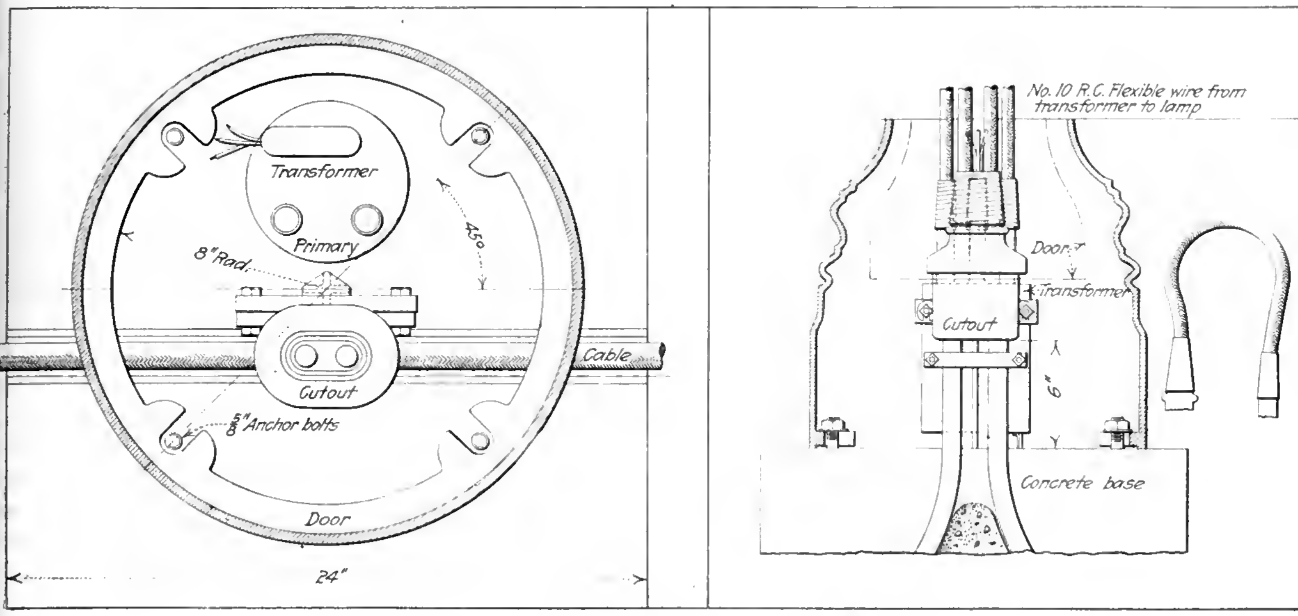
At present there are 6,206 lamps installed, of which 3,706 are rated at 600 cp. Twelve hundred and twenty-five of these are installed on ornamental posts and 2,311 on brackets mounted on trolley poles. There are still 3,781 250-cp. lamps to install on trolley-pole brackets, and it is expected that before long the total number of lamps on the system will reach 12,000. The cast-iron ornamental post used is shown in an accompanying illustration. A No. 107 "Novalux" unit with form T6 "Novalux" top is used with the 600-cp. lamps. No. 109 unit is used with an ornamental post. In the majority of cases the lamp posts used bring the center of the lamp 14½ ft. above the ground, though in one residence district a post with a distance of 11 ft. to the center of the lamp is employed. This is to meet a special condition and is not recommended as a regular practice.

In the base of each lamp standard is a cut-out bolted to a metal support anchored in the concrete. Alongside this support is a transformer with leads running directly to the cut-out. The cut-out is made up of a cast-iron jacket and a porcelain top carrying the contacts. The cables are sealed into the bottom of the cut-out with compound so that the cable sheaths are insulated from each other. The form of construction is such that in case of an accident which tears the post down there is little chance of an injury to the cable, since the top of the cut-out merely pulls out and the pole and transformer may be jerked free of the foundation without putting any strain on the cable. This has already happened in several instances without any disturbance to the cables. Moreover, in case work must be done on the installation a dummy top may be put on the cut-out and the pole and all other parts removed without affecting the rest of the installations in service. Any live parts are thoroughly protected.

Generally there is only one transformer installed in these post bases. However, to take care of lights placed in the street to give warning of street intersections arrangements are made for the installation of a second cut-out in the base of the nearest post, and the circuit for this lamp is carried underground to the center of the street. This makes these warning signs a part of the regular street-lighting system.

For trolley-pole installations a special bracket is used



CONCRETE FOUNDATION AND ARRANGEMENT OF TRANSFORMER AND CUT-OUT

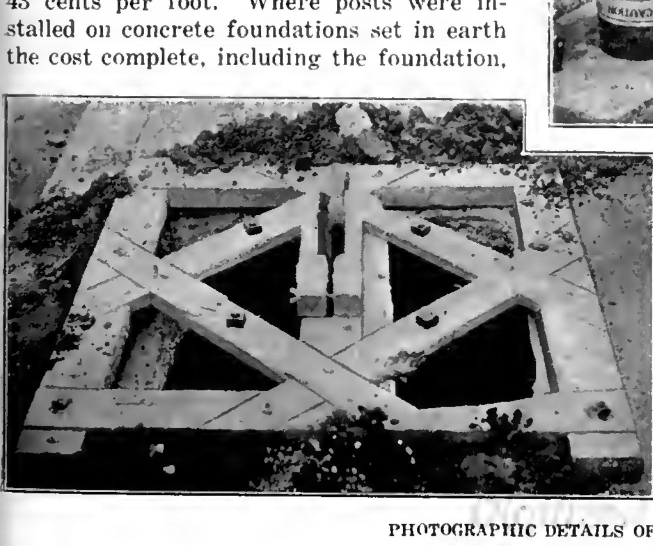
which involves no novel features. Care has been taken to get the best possible appearance. For these installations the conductors are run overhead on the trolley poles and the compensators and cut-outs are mounted on the poles above the bracket, the lamp conductors being taken from the compensators to the interior of the pole and thence to the bracket.

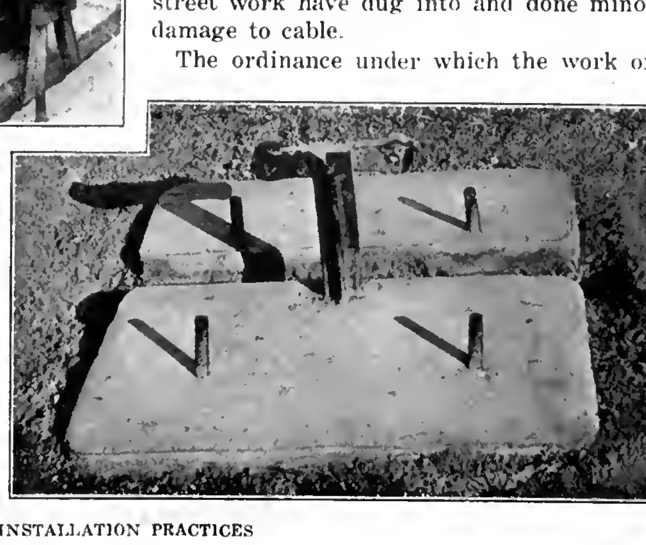
### Some Installation Costs

A variety of conditions had to be contended with so that no statement of average costs would have any meaning. A few costs under specific conditions may, none the less, be of interest. A number of the ornamental posts had to be installed in places where it was necessary to place the conductors in channels cut in concrete walks. In a typical case of this kind the cost of the post installed complete, including wiring, labor and all materials up to the cable, was $131. Anchor bolts were used in the sidewalks to hold the post in place. The installation of cable in the sidewalks, including the cable itself, channeling and the repair of sidewalks, cost approximately 43 cents per foot. Where posts were installed on concrete foundations set in earth the cost complete, including the foundation, ran about $130. The labor cost of installing the foundation and the cut-out in these cases was approximately $12, including excavation. In a typical instance of cable installation which covers a lot of about 12,000 ft. the cost was slightly over 9 cents. This was for the labor of trenching and the cost of placing the cable as well as for replacing sod and otherwise repairing the parking in which the cable was laid. A typical installation cost for cable installed complete is approximately 23 cents per foot. The street crossings where high-grade pavement was excavated cost approximately $2.26 per trench foot complete, including the 2-in. fiber conduit and cable used and the repairs to the pavement. In the outlying districts with the cheaper type of bitumen pavement this cost was approximately $1 per foot.

A large part of the present installation has been operating for nearly a year. In that time almost no trouble has occurred outside of accidents incident to traffic, as where posts are run into and knocked down. One case of trouble with a cut-out due to a loose connection has been recorded. In several instances laborers employed on other street work have dug into and done minor damage to cable.

The ordinance under which the work of



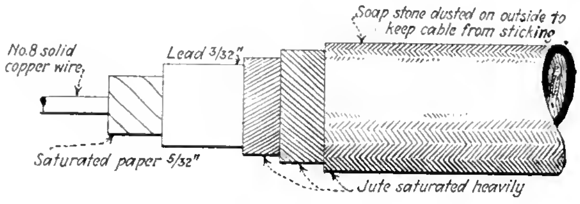


PHOTOGRAPHIC DETAILS OF INSTALLATION PRACTICES

installing the system was carried out was passed in May, 1921. It provides the following schedule of prices for the various types of lamps used:

For 600-cp. series street lamps, equipped with "Novalux" units, supported by posts at an elevation of 14 ft. 6 in. from the ground and supplied from underground circuits, necessitating channeling or excavation in sidewalks in order to install the necessary underground cable; price per lamp per annum, $78.

For 600-cp. series street lamps, equipped with "Novalux"



TYPE OF CABLE USED FOR UNDERGROUND STREET-LIGHTING CIRCUITS

The ordinary type of armored cable used for burial directly in the earth did not seem to offer enough protection against mechanical injury to justify the expense. This cable with a heavily impregnated jute covering outside the lead was used, and for protection against electrolysis troubles dependence is placed on this covering and the fact that the cable is broken at each post and the sections thoroughly insulated from one another.

units, supported by posts at an elevation of 14 ft. 6 in. from the ground and supplied from underground circuits, necessitating channeling or excavation in grass plats in order to install the necessary underground cable; price per lamp per annum, $67.

For 400-cp. series street lamps, equipped with "Novalux" units, supported by posts at an elevation of 14 ft. 6 in. from the ground and supplied from underground circuits, necessitating channeling or excavating in sidewalks in order to install the necessary underground cable; price per lamp per annum, $69.

For 400-cp. series street lamps equipped with "Novalux" units, supported by posts at an elevation of 14 ft. 6 in. from the ground and supplied from underground circuits, necessitating channeling or excavating in grass plats in order to install the necessary cable; price per lamp per annum, $58.

For 600-cp. series street lamps, equipped with "Novalux" units, supported by brackets on trolley poles and supplied from overhead circuits; price per lamp per annum, $57.50.

For 400-cp. series street lamps, equipped with "Novalux" units, supported by brackets on trolley poles and supplied from overhead circuits; price per lamp per annum, $48.

For 600-cp. series street lamps, suspended from mast arms attached to wooden poles and supplied from overhead circuits; price per lamps per annum, $55.

For 250-cp. series street lamps, suspended from mast arms attached to wooden poles and supplied from overhead circuits; price per lamp per annum, $34.

For 100-cp. multiple street lamps, supported by posts and supplied from underground circuits; price per lamp per annum, $24.

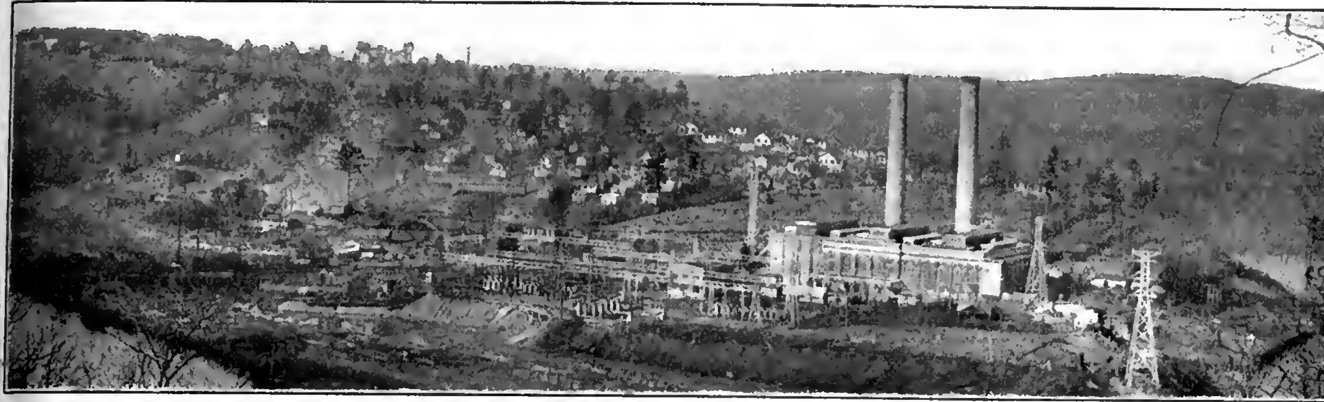
For 100-cp. street lamps used in "traffic standards," now installed or to be installed by the city at street intersections: In case the city shall furnish, install and maintain at its expense all "traffic standards" referred to in this class of street lighting the company shall extend its lines to supply such street lamps and will at its expense maintain the lines, supplying the light and the incandescent lamp; price per lamp per annum, $30.

In this contract the city has the option of purchasing at the end of ten years or any other five-year period thereafter the entire plant, property and equipment devoted exclusively to the furnishing of street-lighting service at the cost to the company less the accumulated depreciation at an annual rate of 3.5 per cent per annum at the time the option to purchase is exercised.

### City to Allow Depreciation

Accumulated depreciation shall be reduced to the extent of any reinvestments of depreciation reserve made by the company in its plant used for street-lighting service to the city. Deferred maintenance, if any, shall be considered at the time of purchase. The term "cost to the company" is specified as meaning the original construction cost of the plant and property devoted exclusively to street-lighting service, including a percentage to be agreed upon by the parties at the time of purchase to cover the cost of organization and legal expenses, engineering, interest, insurance, taxes and injuries and damages during construction. No allowance will be made in the purchase price for going value, franchise value, cost of promotion, bond discount, brokerage commissions, development losses or operating losses. The price to be paid for lamps is to be based on the cost of the posts and glassware used. Any price in excess of this will call for an adjustment of the rates. The city has the right to select the posts, brackets and glassware to be used.

TRENCHING FOR STREET-LIGHTING CABLE



GORGAS STEAM STATION OF THE ALABAMA POWER COMPANY

# Salvaging a War Contract

## How the Gorgas Steam Station, Erected by the Government on the Warrior River, Has Continued to Function and to Serve the Interconnected Network and Industries of the Southeast with Power

By R. D. COOMBS*
*Consulting Engineer, New York*

THE extension of the Gorgas steam plant on the Warrior River in Alabama was made by the War Department to assure an early and adequate supply of power for the construction and operation of the United States nitrate plant then being built at Sheffield, Ala.

When the government, as a war measure, decided to construct the air-nitrate plants at Sheffield, in order that a war necessity might be guaranteed, a very important factor to be worked out in conjunction therewith was the source of the supply of electric power for construction purposes and a guarantee that such power would be available very promptly. For the government to depend on any water power from Muscle Shoals was out of the question, as was also dependence on the completion of new steam-power facilities at Sheffield. It would have involved a delay of several years if the construction of the nitrate plant had awaited the building and completion of water-power plants at Muscle Shoals, and to have delayed the construction of the nitrate plants pending the building from the ground up of a complete steam plant at Sheffield would have involved delay for a period of more than one year.

The Alabama Power Company at this time was operating a large hydro-electric plant at Lock 12 on the Coosa River, Alabama, and this plant was connected by high-tension transmission lines to its steam plant at Gadsden, Ala., and to its much larger steam plant at Gorgas on the Warrior River, the latter plant being approximately 90 miles south of Sheffield. The Gorgas plant was an exceptionally efficient one as the power company owned and operated its own coal mines at the plant and was thus able to avoid the heavy freight charge which ordinarily constitutes a large proportion of the cost of coal for steam-power plants.

As the Alabama Power Company therefore owned and operated a large and dependable power producing and distributing system throughout Alabama, situated less than 100 miles from the proposed nitrate plants at Sheffield, it was a logical conclusion for the government to call upon the power company to supply quickly the power needed to permit of the rapid construction of the all-important nitrate plant.

### EXTENSION OF GORGAS STATION

When the Alabama Power Company built its Gorgas plant provision for future extension to a capacity approximately three times the capacity as first installed was made by expenditures for extra land, foundations, water intakes and discharge culverts. It was therefore possible to make a very important saving in time by utilizing the work already done.

The War Department decided that the best and quickest way to obtain both the power needed immediately and also a portion of the total subsequent power was to build a high-tension transmission line from the existent facilities of Gorgas to the proposed nitrate plant at Sheffield so that power would be available from the power company's system in the course of a few months, and also to install additional equipment in the spaces previously provided in the steam plant at Gorgas. As it was impossible for the power company to raise the necessary funds by financing in the ordinary manner, owing partly to the war emergency control of the government which prohibited the financing of projects of this nature, the government contracted with the power company, as its agent, to install the extensions at government expense, with the agreement that the power company should have the right to purchase at some future time at a fair value the improvements paid for by the government.

Ordinarily a 110,000-volt, 30,000-kw. transmission line, with provision for additional circuits and situated in rather rough country, would be built with long-span steel towers and would be intended as a permanent installation.

The known facts governing the Gorgas-Sheffield line

*Major Coombs was the officer in charge and agent of the contracting officer in the Alabama Power Company contract.

at the time of its design, in the winter of 1917-1918, compelled a different type of construction. It was of the utmost importance that construction power, then estimated as 2,000 kw., followed by furnace-test power of 10,000 kw., should be made available from some existing source within six months. The nearest and most available source of power was the Alabama Power Company system. In addition to the above preliminary blocks of power it was desired that approximately 30,000 kw. be supplied by an addition to the Gorgas steam station for use in the final operation of the nitrate plant and that this power be available in about nine months. Further, it was contemplated that in emergency an additional circuit might be required, the power therefor to be commandeered from the system of the power company. It should be noted that, rightly or wrongly, we considered power in terms of kilowatts bearing the stamp U. S. A. and available at any or all times, 100 per cent capacity, twenty-four hours a day, if needed.

A 110,000-VOLT LINE ADJACENT TO A 44,000-VOLT LINE ON THE SAME RIGHT-OF-WAY

In the circumstances the writer decided in favor of wooden poles, first because the steel market was facing a chaotic condition and no delay was permissible, and second because the life of the line was uncertain. The Muscle Shoals dam project had not then been authorized. It was also possible to construct a long span, H-frame one-circuit line and duplicate it if necessary without interruption to service.

### Details of Transmission Line

Right-of-way was comparatively inexpensive, and the right to trim outside the right-of-way was readily obtained. Therefore the structures were placed near the sides of the 100-ft. width of way, with a small side clearance, the center being reserved for a 44,000-volt existing circuit to Jasper and for the government telephone line. The route of the line lay through rough, scrub-timbered, undeveloped country with very poor roads and these not often parallel to the right-of-way. Cutting and clearing began in January, 1918, during what was said to have been one of the worst winters of local record. The line crews, scattered in from three to six camps along the route, suffered considerably from the cold and wet, the negroes being particularly susceptible to pneumonia.

In five months from the ordering of supplies and the start of right-of-way purchase and clearing, which were approximately simultaneous, the 90-mile transmission line was ready for service and considerable work had been done on the permanent substations. Although this progress is not offered as record-breaking, it represents a very intense effort and is entitled to high rank of performance in view of the conditions.

The wooden poles used were mostly creosoted Southern pine, with some Western cedar in the northern end of the line. Cross-arms were creosoted long-leaf yellow pine, 6 in. x 8 in. x 29 ft., with a grounding wire connected to each insulator eyebolt. In view of the angle braces used with these arms it might appear that the arms were unduly large, but experience with this line indicated that they were not too large since there were some indications of bending in the arms. It seems probable that suspension braces instead of compression braces might eliminate this tendency.

It may be noted that the horizontal separation of conductors on tangent suspension frames is 14 ft., which is less than will be required by certain recent specifications, and that thus far no failures have resulted.

The power-house construction presented no unusual difficulties, as it was essentially an extension of an existing station by the addition of a boiler house, a 30,000-kw. turbine and accessories, though it is perhaps unusual in the East to have to convey all materials and equipment by river barge 18 miles from the rail head.

### Gorgas Substation

The Gorgas substation was designed to make the Gorgas-Sheffield line an integral part of the power system so that in any apparent combination of conditions it would be possible to obtain power from the government unit, the Alabama Power Company unit or the system or connections of the power company.

The substation design followed the usual lines of a high-voltage latticed-steel structure with concrete foundations. An incident occurred in connection with this substation indicating the rapid action of corrosive agencies. In the incidental filling in of low ground adjoining the river with hot ashes from the boiler house the ashes were dumped close to the guard fence and to one of the supporting columns of the substation. Either rain or fog from the river, acting in conjunction with the fumes from the ashes, started a very noticeable corrosion first of the galvanized-wire fence and then of the painted column.

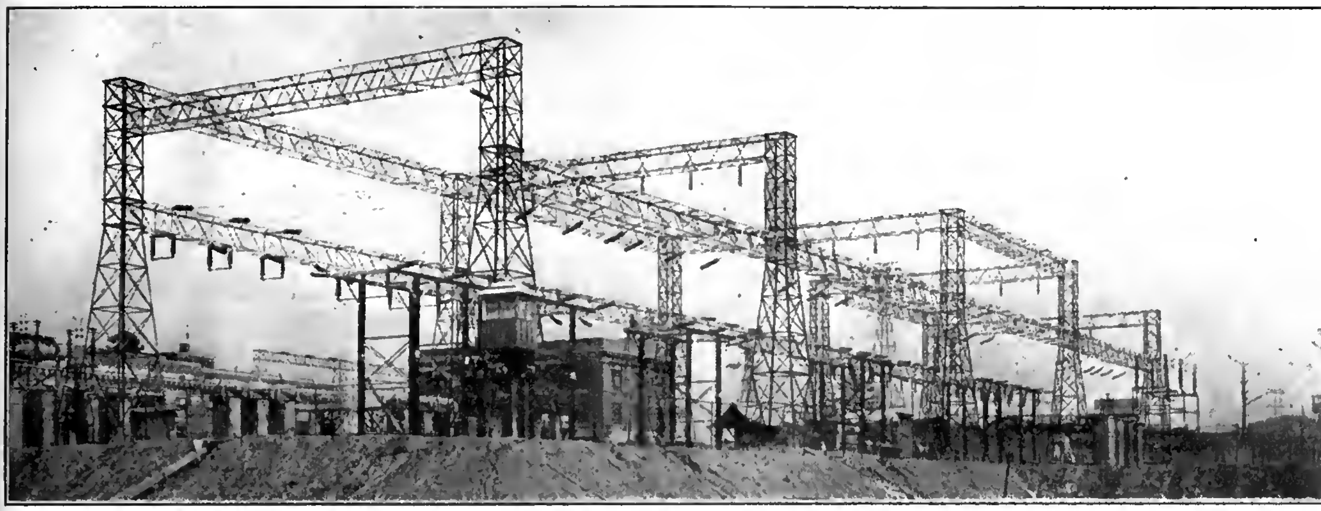
### Contract with Ordnance Department

Under the contract the Alabama Power Company, as an agent of the United States, was in about the position of an engineering-contracting concern doing work under the supervision of an owner. However, the position of the agent was different from that of the peacetime contractor, since all purchases were made after the specific approval of the Ordnance Department, and the Ordnance Department inspected and paid for them. On the other hand, the agent was in fact adding to an

operating station of its own and expected ultimately to purchase the government's construction. Further, the contract contained a limit to the fee to be paid the power company for service, etc. Under the circumstances it is hard to discover a reason why either the power company or the Ordnance Department should have had any tendency to follow a course other than the one pursued—to build a workmanlike job as fast as possible.

After the haze of accusation and counter-accusation arising from the supply contracts of the war, it is interesting to be able to discern at least one type of such contracts which now appears to have had a relatively high salvage value from the standpoint of the public interest. Further, it would appear that the ultimate benefit will be greater than was to be foreseen at the beginning of the contracts in question.

Starting from the premise, which was partly the understanding if not indeed the law of the appropriations, that the war supply expenditures were temporary expenses rather than permanent governmental underwritings, it yet appears that the public utility type of construction contract was in fact a permanent improvement in the public interest. On the other hand, it migh' be said—indeed, it was said—that there was no sure peacetime need of such additions and that there would be no market for the power until a long time after the war.



OUTDOOR SUBSTATION OF ALABAMA POWER COMPANY

### Peace-Time Utilization of Station

In a certain section before the war there was no interconnection or transfer of power. Compare that situation with the power and textile companies of Georgia and the Carolinas joining in a petition to the government to lease the Muscle Shoals power plant to the Alabama Power Company so that company could transfer power to their communities. During the war the impetus to interconnection was greatly strengthened, and the Alabama power and Georgia power companies were afterward connected through a 50-mile transmission line. Next the Alabama Power Company found it necessary and desirable to rent the use of the government power station at Gorgas, which was an extension of its own station at that point, and then to rent the government station at Muscle Shoals. Along came the coal strike, and Alabama, a coal state, needed electric power to replace the coal which was not being mined. On top of the coal strike came the driest year, in a hydro-electric sense, that region had ever known and a pressing need for public utility service and the power to transfer service. As a result the industries of the Southeast clear up to North Carolina were depending to a very considerable extent upon the usefulness in public utility service of the War Department's contracts.

The Gorgas project has already made a return to the government and to the public and stands out above the ordinary war-time contract in the value of this return and also in the relative salvage value of the plant. Operated as it has been, in co-ordination with the large power-producing facilities of the Southeast, it has been a means of accelerating the growth of industry, and, particularly in the past two years of low water flow in the rivers, the operation of this plant and the distribution of the energy to the states of the Southeast, has permitted the operation of numbers of cotton mills which otherwise would have closed down and thrown their employees out of work.

It is the writer's understanding that the Alabama Power Company has made an offer to the government to purchase for cash the portion of the Gorgas plant now the property of the government and has agreed to pay a sum which is equal to or greater than the present construction cost of these facilities. An income to the government in the form of rental for the use of its Gorgas project, the great benefit to industry throughout the South, which otherwise would have been compelled to curtail operations, and the salvage value of the plant as measured by the offer of the power company under the contract to buy it for cash, are among the benefits which have accrued to the government and to the public.

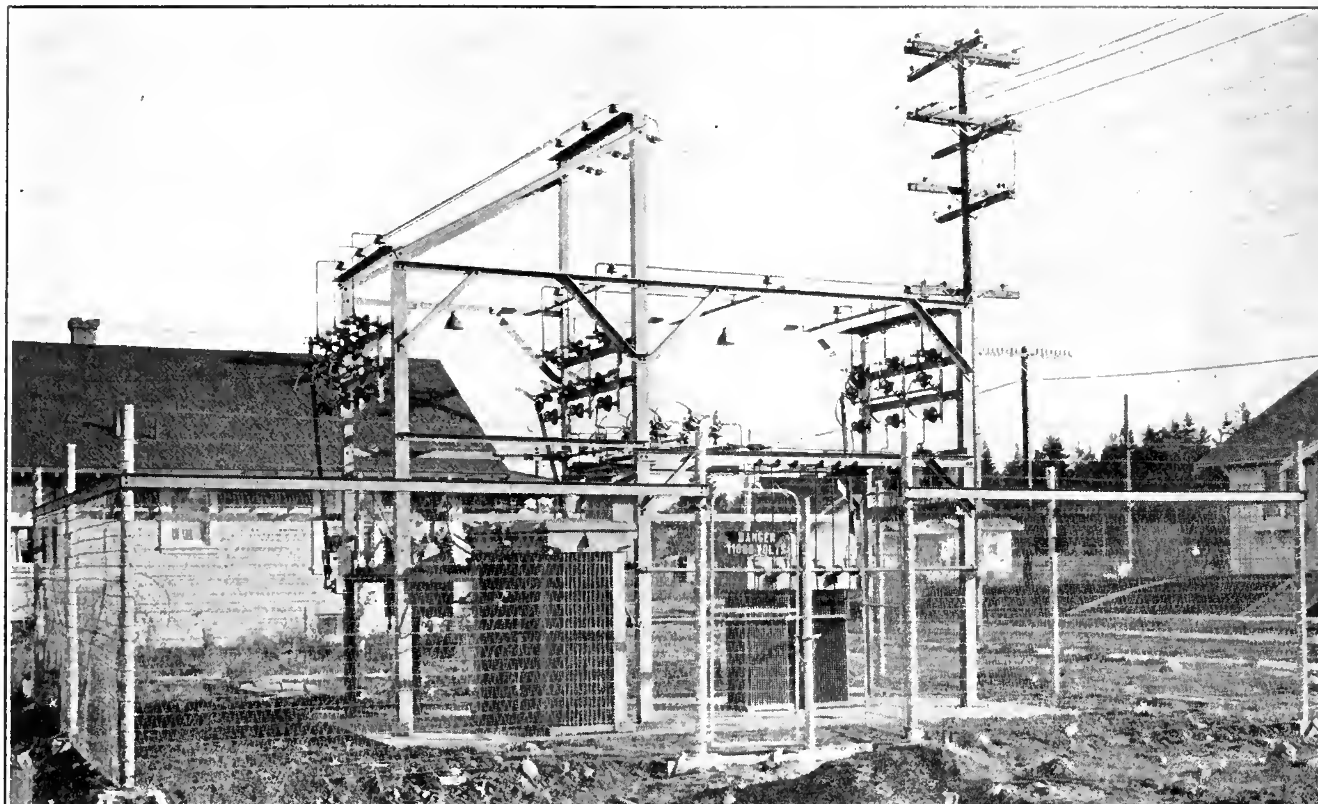
At the site of the nitrate plant at Sheffield, and entirely independent of the Gorgas plant, the government built a steam plant of approximately twice the size of the Gorgas plant. This plant was never used and would have been idle now had not the power companies leased it from the government and distributed its power over their systems.

The wide distribution of power from these plants to industries throughout the Southeast is to the writer a most convincing argument that the power to be created at Muscle Shoals dam should be made available for distribution to industries in the whole Southeast rather than be kept for local use in the vicinity of Sheffield.

# Outdoor Substation for 2,400 Volts

## Including Real Estate, the Type of Outdoor Substation for City Distribution Adopted in Portland, Ore., Cost About $8,500 Each—Construction Features Shown and Design Details

By E. D. SEARING
*Construction Engineer Portland (Ore.) Railway, Light & Power Company*



OUTDOOR SUBSTATIONS OF THIS TYPE ARE USED IN RESIDENTIAL DISTRICTS OF PORTLAND, ORE., TO SUPPLY 2,400-VOLT DISTRIBUTION

MANY changes in the distribution systems of power companies to relieve the overloaded conditions of lighting and power feeders have become necessary as a result of the increase in load due to the building activity and the general business revival throughout the country. Some companies are going to 4,000-volt, four-wire, star-connected systems, while others are changing over single-phase, 2,400-volt feeders to three-phase, or increasing the size of copper in existing three-phase circuits.

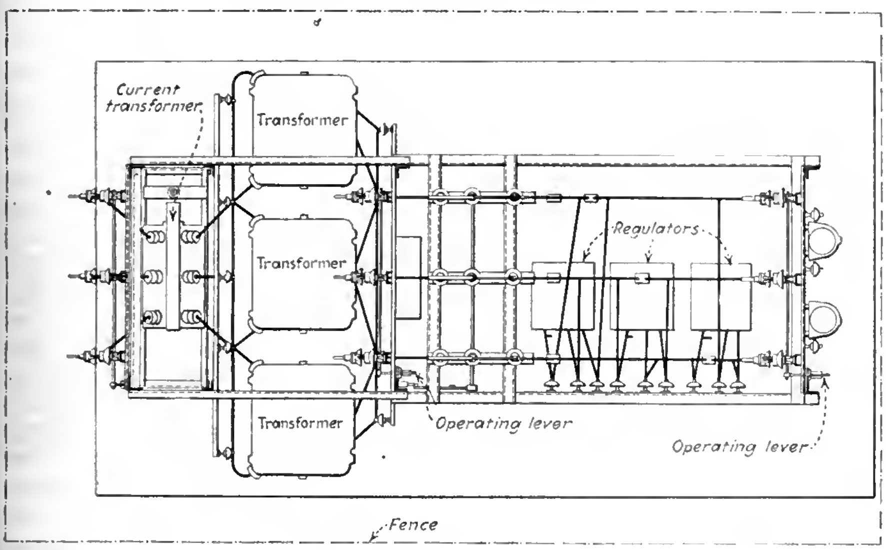
The practice of the Portland (Ore.) Railway, Light & Power Company in the past has been to supply all 2,400-volt city distribution circuits from substations having one or more personal attendants. The installation of feeders from such substations usually consisted of two wires forming a single-phase circuit. As the load grew a third wire would be run, making the circuit three-phase, thereby insuring a greater capacity and more efficient utilization of the copper. Following the period of winter load in 1920-1921, it became apparent that some means of supplementing the existing distribution circuits was necessary. The greater use of electricity per customer and a large increase in the number of customers established the fact that either more feeders would have to be run from existing stations or that other provisions must be made to handle the growing load. The existing substations, besides being located considerable distances from the centers of load, were in most cases found already congested with equipment and outgoing feeder circuits.

From an economic study it was seen that outdoor substations located near the center of load were preferable, and as a result this solution of the problem was adopted. Consideration from the standpoint of reliability of service and accessibility for inspection and repair led to the adoption of a ground location for the equipment in preference to the pole-type structure sometimes employed. A study of the districts being served was made and new centers of load located. A canvass of vacant lots in the vicinity of these distribution points was made, and suitable property on which to locate the outdoor substations was purchased.

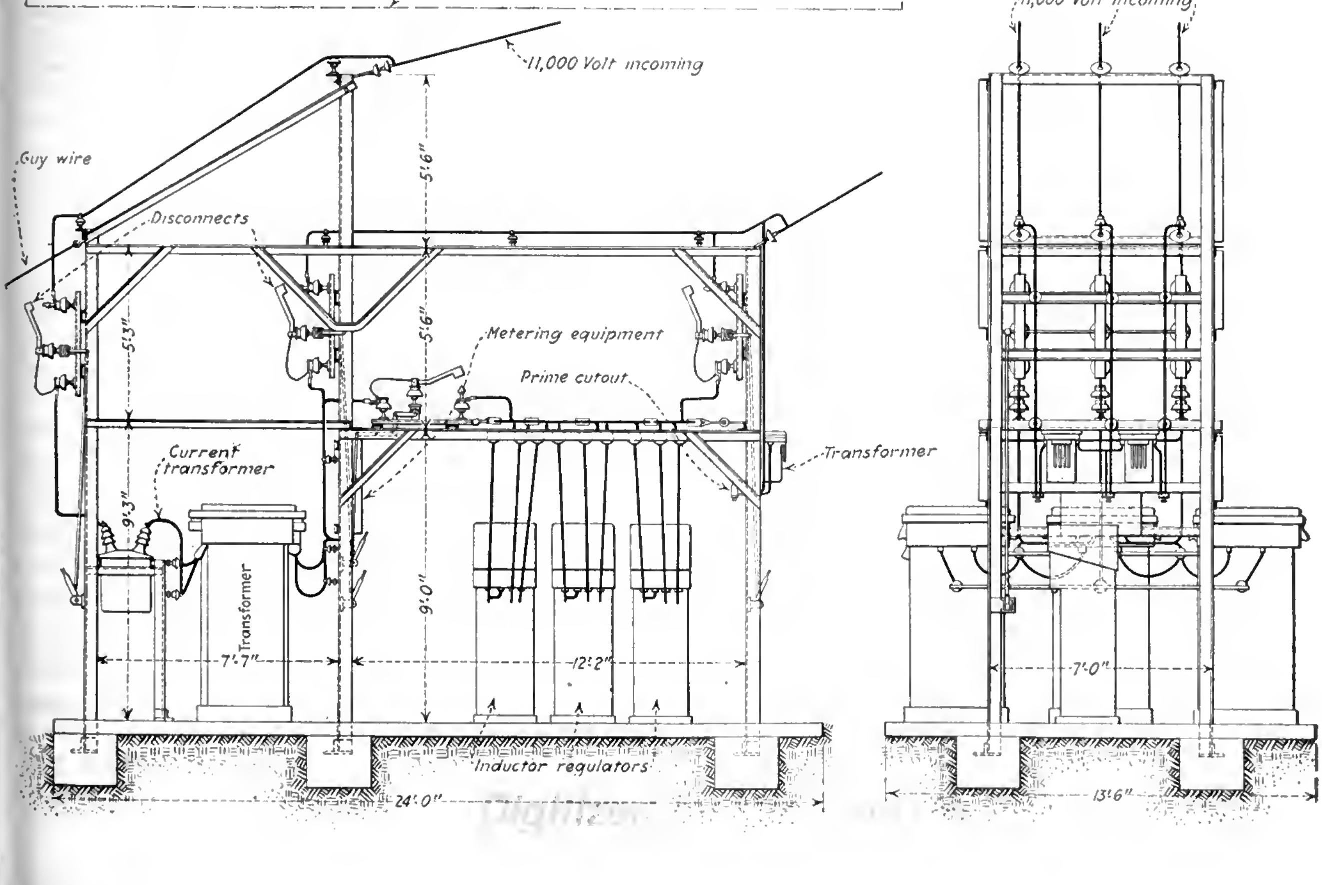
The type of substation decided upon called for step-down from 11,000 volts to 2,400 volts. Connection to each substation was made from existing 11,000-volt tie lines between substations having attendants, and

new lines were run where no 11,000-volt lines already existed. The company's low-tension transmission system consists of 11,000-volt tie lines between various substations having attendants. Usually each substation is fed from two or more adjacent substations by 11,000-volt tie lines and occasionally from the 57,000-volt transmission lines as well. It will thus be seen that the system of 11,000-volt lines is somewhat analogous to a spider-web network. This arrangement insures that each substation is normally fed from at least two sources. The 11,000-volt tie lines which feed the outdoor substations have pole-top sectionalizing disconnecting switches on either side of the connection to the substation, thereby making it possible to feed the outdoor station in case of line trouble from the substation on either end of the tie line.

The outdoor substations are each designed to contain three 200-kva., 11,000/2,400-volt, single-phase transformers, three 150-amp., 10 per cent buck-or-boost induction regulators and one 11,000-volt automatic oil circuit breaker. Control and auxiliary equipment consist of disconnecting switches between the oil circuit breaker and the line and between the 2,400-volt bus and feeder, also for shunting out the induction feeder regulators. Two 1½-kva., 2,400/120-240-volt transformers are provided for furnishing power to the regulator motors, lighting, and potential for a recording demand watt-hour meter. The meter, together with current transformers, is installed in a weatherproof metal box mounted on the structure. The initial installation generally includes only two transformers and two regulators, the third transformer and regulator being added as the growth of load necessitates. The transformers and regulators are mounted on a concrete slab on the ground, a structural-steel framework being erected to support the disconnecting switches, oil



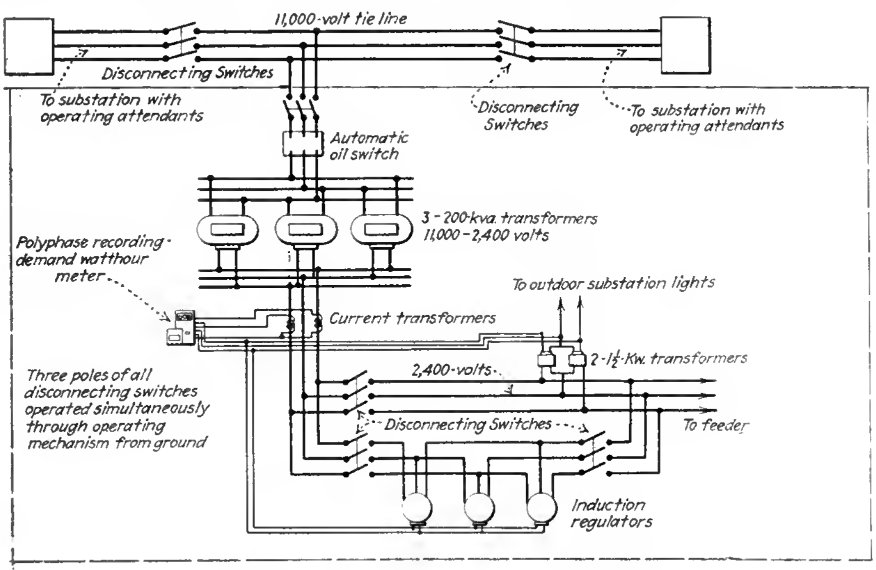
POLE TOP DISCONNECTS MAKE IT POSSIBLE TO FEED THE STATION FROM EITHER TIE LINE



circuit breaker and buses for the incoming and outgoing circuits.

The equipment is inclosed by a close-mesh, non-climbable type of woven wire fence surrounded with three barbed wires, the fence being supported on pipe supports set in concrete. Entrance to the inclosure is provided by a double swinging steel gate with a good padlock to insure protection.

The accompanying illustration shows one of the typical outdoor substations. There are five of these substations in operation at the present time, and plans are now under way for the construction of four more during the early part of 1923. The equipment and its arrangement in all substations are identical. A telephone mounted in a weatherproof metal box is installed within the fenced inclosure for use in case of substation trouble or in line patrolling. This telephone is connected with the company's railway and load-dispatching telephone systems. A number of lamps are provided on



WIRING FOR OUTDOOR SUBSTATIONS, TRANSFORMERS AND TIE LINES

a circuit controlled by a switch for use at night should occasion require. The disconnecting switches are all arranged for simultaneous three-pole operation by handles placed on the structural framework and accessible from the ground. The output from each of the substations is ascertained from a recording demand watthour meter which is read each day. The hourly distribution of the load is found from the demand records of the same meter.

Consideration is being given to the addition of suitable automatic reclosing equipment to the oil circuit breaker as insurance against extensive service interruptions due to feeder trouble. In case of trouble the reclosing equipment would be designed to close the oil circuit breaker periodically a sufficient number of times either to allow the trouble to clear itself or to establish the fact that the trouble is serious, in which case the switch will automatically lock open and the trouble will require the attention of troublemen to clear it.

So far these substations have fully served their purpose, and there is every reason to recommend their general adoption under similar conditions. The average cost of each of the installations complete, including real estate, was about $8,500; this is very reasonable in comparison with the indoor type of substation.

## Why to Use the Radio Telephone

By H. L. WILLS
Georgia Railway & Power Company

THE development and operation of large electric power generating stations and widespread distributing systems would have been delayed and hampered had there been no means for keeping in close and almost instant communication with the activities of those engaged in the construction and operation of the more or less distant units.

During the time when electric service systems were distributed over relatively small areas and power stations were within easy reach of the local telephone lines, a ready means for inter-system communication was obtained through the service of the telephone companies. It soon developed, however, that valuable time was lost by inattention and mistakes of telephone operators, the chance of lines wanted being in use and similar difficulties. Moreover, group conferences were almost impossible. As an emergency measure private telephone lines were installed between the most important points, and as the power systems expanded these private telephone lines extended until in some cases a very real and very busy telephone system resulted and the once "private line" was lost in the system.

Then the call for some means of intercommunication between these private systems and the public telephone system had to be answered, and as a result the old troubles—"Line busy," "Number Six-two-eight doesn't answer," overworked or inattentive operators—flourish as of yore, the only difference being that a few minutes in the business of yesteryear was of less importance than a few minor fractions of a minute are now.

Today another means of communication is available for use—the radio telephone—and where the importance of communication service warrants, advantage should be taken of it, not with the idea that it is a cure-all or an infallible agent, but with the conviction that it is a valuable reinforcement to lines of communication.

It has been urged that the radio telephone is not reliable. How about the reliability of the wire lines when wind, flood, fire, power-line troubles and the troubles of the telephone line and apparatus cut off communication, leaving one absolutely helpless so far as connection with the remote power house or with some important switching center is concerned? What would one not give sometimes to be able to put across a half-dozen sharp, incisive, full-of-meaning words and hear the "All right, I get you, boss," come back assuring him that co-ordinated effort toward the restoration of an interrupted service is under way? Has not many a central-station man added a year to his age in an hour's time as he sat with tense nerves and toyed in impotent rage with a worse than useless telephone? Wouldn't he try another way if he had an opportunity? The radio telephone offers this opportunity. With it one almost always gets a message through some way. It has already proved to be a faithful tool to have in reserve.

# New Sequence System of Polyphase Meters

## A Proposed Method of Meters and Metering for the General Case of Polyphase Circuits Based on Sequence Analyses—Simplicity and Accuracy Are the Keynotes of the Plan

By R. D. EVANS

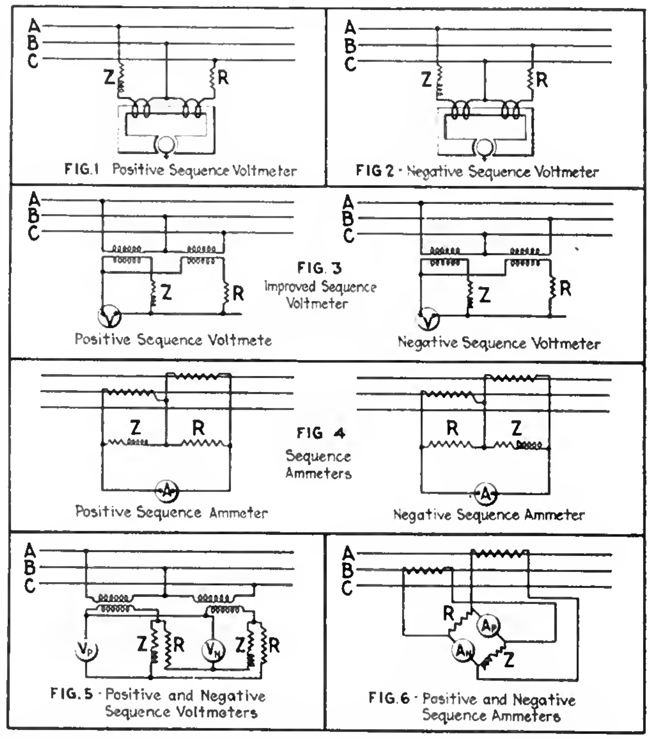
*General Engineer Westinghouse Electric & Manufacturing Company*

A NEW system of measuring devices for polyphase circuits has been proposed. The new measuring devices form a complete system for polyphase circuits and include voltmeters, ammeters, wattmeters, reactive wattmeters, power-factor meters, unbalance meters and also relays. The advantages of the proposed system in comparison with the systems in use at present may be stated as (1) simpler and more direct indications of circuit conditions, and (2) the requirements of fewer metering elements to indicate circuit conditions.

The present systems of measuring devices for polyphase circuits in general indicate phase quantities, as voltages or currents, or summate the phase quantities, as in the case of the polyphase wattmeter. In the development of these systems for polyphase circuits consideration was given principally to the "particular case," i.e., the balanced circuit. The "general" case of the polyphase circuit—i.e., the unbalanced circuit—was not well understood as evidenced by the discussion as to the definition of "polyphase power factor."

A method for analyzing unbalanced polyphase circuit conditions was presented by C. L. Fortescue in his paper on "Symmetrical Co-ordinates." This method is based on the fact that any unbalanced polyphase system may be resolved into two or more balanced or symmetrical systems. For example, in a three-phase, three-wire circuit an unbalanced system of currents may be resolved into two symmetrical three-phase systems in which the currents of one system reach their maxima in the different phases in a positive sequence, as *A*, *B*, *C*, and the currents of the other system reach their maxima in the negative sequence, *C*, *B*, *A*. The method used here of resolving currents into components, positive and negative sequence, is similar to the method now in general use for resolving currents into components in phase, or active, and out-of-phase, or reactive. The reasons for the resolution of the currents into components for the two cases are the same, namely, that the different components have different effects, thus simplifying the solution of the problem. One advantage of this method resides in the fact that it is possible to deal with a few symmetrical systems—two for the three-phase, three-wire system—in varying proportions instead of dealing with an infinite number of combinations of unbalanced systems. Two results this investigation has produced are (1) a revision in the conceptions of polyphase circuit measurements, and (2) recognition of the desirability of a new system of measuring devices which is simpler and more accurate for the general application.

The new measuring devices are based on the resolution of the different quantities of the "general" polyphase circuit into the different phase-sequence components. Each of these phase-sequence components, if present on a polyphase circuit, may be measured. The method of separating these components is accomplished by the devices which will be described in the latter part of this article.



METERS USING THE SEQUENCE PRINCIPLE AFFORD SIMPLICITY IN CONNECTIONS, ACCURACY IN METERING AND RELIABLE RELAYS FOR PROTECTIVE PURPOSES

The following explanations of the phase-sequence devices will, for the sake of brevity and clearness, be based on their application to the three-phase, three-wire circuit. For these circuits, the relations between the different voltages may be expressed as follows:

$$E_A = E_P + E_N, \quad (1)$$

$$E_B = a^2 E_P + a E_N,^* \quad (2)$$

$$E_C = a E_P + a^2 E_N, \quad (3)$$

where $E_A$, $E_B$ and $E_C$ are the line voltages and $E_P$ and $E_N$ are the positive and negative sequence components of voltages respectively. The solutions of these equations for positive and negative sequence voltages are:

$$E_P = \frac{E_A - aE_C}{1 - a^2} \quad (4)$$

$$E_N = \frac{E_A - aE_B}{1 - a^2} \quad (5)$$

These equations show how the voltage of one sequence component may be obtained from the voltages measured in the usual way.

The next step is to show that the separation of the

---

*$a$ is an operator similar to $j$. $a$ is equal to $(-\frac{1}{2} + j\sqrt{3}/2)$ and effects a rotation of 120 deg.; $a^2$, a rotation of 240 deg.; $a^3$, 360 deg.; or $a^3 = 1$.

different phase-sequence voltages, accomplished mathematically as shown above, can be accomplished by measuring instruments. Considering the positive sequence voltage, equation (4), all that is necessary is a meter with one winding taking a current in phase and proportional to the voltage $E_A$, and another winding taking a current proportional to the voltage $E_C$, but with a phase relation of $-a$. Such a meter is shown in Fig. 1. The external impedances, $Z$ and $R$, are of such high value as to determine the magnitude and phase relation of the currents going through the windings. $R$ is a resistance, and the current going through winding 1 is in phase with the voltage $E_A$. The next step is to determine the value of $Z$. The power factor of the impedance must be such that the current is proportional to $-aE_C$. As $a$ represents a rotation of 120 deg., $-a$ represents $-60$ deg., or 60 deg. lag. Hence the impedance must be such as to cause the current in the winding 2 to lag 60 deg. behind the voltage $E_C$. To meet this requirement $Z$ must be equal to $(0.5 + j0.866)R$. Hence this meter measures a quantity proportional to $E_A - aE_C$, and therefore proportional to $E_P$, the positive sequence voltage.

This same conclusion can be obtained in another way by showing that positive sequence voltages cause the meter to register, but negative sequence voltages do not. Hence the meter operates on a system with unbalanced voltages to indicate only the positive sequence voltage.

Negative sequence voltage may be measured in a similar way and by the same meter, only a change in connection is required. The diagram of connections for the meter to measure the sequence voltage is shown in Fig. 2 and the explanation follows directly from equation (5).

This method of measuring the different sequence voltages is generally applicable and may be extended to a different number of phases and to measure other sequence voltages. Another form of the positive and negative sequence voltmeters is shown in Fig. 3. This form appears to be the best for commercial use, as standard meter elements and standard potential transformers are employed.

### Phase-Sequence Ammeters

The different sequence currents may be measured in a manner similar to that of the different sequence voltages. Fig. 4 shows devices for measuring positive and negative sequence currents. The devices shown in Fig. 3 and 4† may be explained in the manner indicated above, or they may be explained from a different viewpoint, that of a network in connection with a standard meter element. This method of viewing the problem is very simple and gives a solution in convenient terms. From this viewpoint a voltmeter or an ammeter consists merely of a meter element which measures voltage or current, depending upon the network which connects it to the circuit. Hence to measure positive sequence current it is only necessary to obtain a network that permits only current of positive sequence to flow in the branch in which the meter element is connected. Such a network is shown in Fig. 4.

It is possible to combine the networks for positive and negative sequence-measuring devices so that separate transformers for each device are not required. Such a combination for measuring positive and negative sequence voltage is shown in Fig. 5, and a corresponding positive and negative sequence-current device‡ is shown in Fig. 6.

†This improved form is due to C. T. Allcutt.

‡This device was suggested by C. L. Fortescue.

### Sequence Wattmeters, Reactive Wattmeters, Power-Factor Meters, Etc.

Having separated out the positive and negative sequence voltages and currents, it becomes evident that it is possible to combine them to measure power, reactive power, and power factor. Standard instruments supplied with positive-sequence voltage and current measure positive-sequence watts, positive-sequence reactive watts and positive-sequence power factor.

A study of the preceding diagrams and explanations will show that there are certain devices now in operation whose success depends upon separating out more or less effectively the different phase-sequence components of voltages or currents. Such devices include those for indicating phase rotation and the ground-current relay operated from three-current transformers on the three-phase grounded neutral circuit. Instead of a number of isolated devices, there is proposed a complete system of devices, all utilizing the same principle.

The phase-sequence-measuring devices are relatively simple, involving standard meter or relay elements with standard types of potential and current transformers and auxiliary networks consisting of resistors and reactors. With the phase-sequence method fewer metering elements are required to indicate circuit conditions. For example, one positive and one negative sequence ammeter will replace three single-phase ammeters. In addition, the phase sequence devices indicate circuit conditions to better advantage. An example in point is the application of the negative-sequence current device as a relay to provide protection against single-phase operation of motors. Some of the advantages of the sequence method of making polyphase power measurements are pointed out in a paper by C. L. Fortescue, entitled "Polyphase Power Measurements," to be presented at the 1923 midwinter convention of the American Institute of Electrical Engineers. In considering the application of the proposed system of measuring devices, there are two cases to be considered: First, one with no unbalance present, in which case the two systems give the same result and the proposed system has the advantage of employing fewer meter elements than are employed at present; second, one with unbalance present, in which case the two systems will give different results and it will probably be desirable to give consideration to unbalance, which is best measured by the system proposed.

## Permissible Electric Drills

THE Bureau of Mines has issued a report embodying the results of an investigation into the matter of permissible electric drills, "permissible" referring to use in gaseous or dust-laden mine atmospheres. The report (Serial 2,434) has been compiled by H. B. Brunot and H. B. Freeman. Two makes of electric drills have successfully met the requirements of the bureau. The formal approval of these drills means that if they were inadvertently operated while immediately surrounded by an explosive mixture of gas as the result of accidental interference with the ventilation, the atmosphere surrounding the drill would not be ignited even though an explosion took place within the equipment.

# Aspects of the Central-Station Sales Effort*

## Necessity of High-Type Service—Customer's Position Reversed in Merchandising Department, Where He Is No Longer a Supplicant

DURING the past few months the sales departments of the central-station industry have furnished a topic for many discussions. It seems to be generally believed that these departments should be more seriously considered, receive more attention and in many instances have the scope of their activities greatly broadened. If the men in such departments have not developed as rapidly as might be desired or the departments been as helpful as they should, the fault may not be entirely their own. In the stress of other problems sales departments have too often been permitted to drift of their own momentum and have not been used to the extent which might have been the case with proper organization training.

In some companies of our industry, even today, the sales department is organized merely to merchandise goods; in other cases it takes on some additional responsibilities for soliciting small-power business; but in few instances does such a department really function in a broad way as a bureau of general business development and as a service department. Only in recent years has more been expected of a sales manager than to be the efficient head of a group of solicitors; but even though this be considered the sole purpose of such an organization, it is not certain that the industry has always reaped the full benefit of it.

### Quality Service Essential

The real mission of the sales department is to sell more electricity by both direct and indirect methods, and merchandising for profit cannot be considered as more than incidental. Probably for several years to come the long-debated question of whether a central station should deal in merchandise at all will continue to be a perennial cause for difference of opinion. It would seem that the answer may be found by considering another question, namely, "By selling merchandise can we render a needful or a desirable service to our customers which they cannot otherwise obtain?" If local dealers and contractors offer but an inadequate service, then most assuredly the central station should fill the gap, even though the transactions themselves may not net a direct and traceable profit.

If the dealer and contractor does this work as well or better than the central station, there does not appear to be much justification for it to remain in a business for which it is not organized and for which it is not pre-eminently equipped. However, even in the latter case it is sometimes urged that central-station merchandising has a very salutary effect upon the methods and practices of other agencies engaged in the distribution of electrical goods.

### Giving the Customer the Advantage

Another view of central-station selling asserts that in all other departments of utility companies the customer's relations are more or less those of a supplicant for service, which is granted him under certain conditions of the central station's making, while the floor of the sales department is a place wherein these relations are reversed. Here the company is actually soliciting favors from its customers, and it is believed by some that to have at least one department which of necessity must have contact with the public from a somewhat different angle is valuable and not to be lightly eliminated.

It is at least generally conceded that the public utility does not desire a monopoly of the merchandising business, that the activities of dealers and contractors all redound to the direct and immediate benefit of the central station, and that the latter should encourage and stimulate the contractor and dealer as far as possible, always having in mind that the central station's most profitable obligation is its customer. Utilities have not always been patient and helpful in their dealings with these outside local agencies. Some sales managers have been trained to expect the value of their services to be measured by the volume of their sales, and all such very naturally look upon the dealer as a rival instead of as an ally. This appears to be a somewhat narrow viewpoint which should be found easy to correct.

### Are Our Goods Well Sold?

Those who are responsible for companies having established merchandising departments may well ask themselves: "Are our goods well sold?" Speaking very generally, the answer is "No," or at least not so well sold as they will be when volume ceases to be the goal of sales effort. There is room for much improvement in this respect. Stating the problem in other words, it would be: "Do our salesmen make people buy their goods rather than make them *want* to buy them?" and therein lies an important distinction.

Customers' closets and shelves contain many devices which they bought but did not want, and so they are out of use, producing neither revenue for the utility nor satisfaction for the owner. Some test inspections have shown as high as 25 per cent of owned devices out of use, largely because the keen desire for the service which the appliance could render was not sold with the device itself. In most instances, probably, this desire could have been implanted.

Doubtless more than 50 per cent of the electrical devices in customers' homes are not used to anywhere near their possibilities. Sweeping a floor is only one of many uses to which a suction cleaner may be put; percolators will do more than make coffee; flatirons are capable of far more service than merely smoothing out damp cloth, and yet a discussion with a selected group of owners of such devices proves that they know little or nothing of their possibilities. It must be assumed that the salesman did not know them either, or that he was merely marketing an energy-consuming device and considered it no part of his duty to sell a service, his mission having ended with the making out of his sales slip.

In our calculations of the possibilities of load building we should not overlook the one of better selling. The dealer is interested in selling those devices yielding him the greatest profit. It chances that nearly all such are the most insignificant consumers of electricity, while, on the other hand, devices which are the best load builders cost so little in the first place that the retailer cannot give more than casual service. If we find upon investigation that those devices which have been poorly

*From an address by H. T. Edgar, division manager Stone & Webster, Inc., Boston, before managers of utilities under the company's administration.

sold have been marketed by the dealer, we can at least consider the desirability of reselling them through advertising, service calls, etc. In any event our own sales departments must become something more than order takers and record writers if they are in any measure to justify their existence. It appears to be rather inconsistent with good business judgment to place so vital a factor as business development in the hands of the type of man who may be attracted by an inadequate salary and whose sole qualifications are those of a clever peddler.

### The Public Relations Opportunity

Like the head of any operating department, the chief of the sales department should be a man capable of contributing real strength to the manager's staff. He should be familiar with the larger problems of public utility operation if he is to bring to his job that broad vision and understanding which now appear essential to successful operation. His position demands that he and his assistants maintain close contact with the public. It would seem to be desirable to select and train our sales managers to represent adequately their companies in that capacity. If they are to be bigger men, they will as a matter of course command larger salaries, but no public utility has yet conclusively determined the limiting value which can be placed upon the services of the right sort of man in this position, assuming that the latter means selling the company and its service to its customers rather than merely selling them energy-consuming devices.

Serious effort to train sales managers in many cases implies supporting them by furnishing better personnel in their departments. It has been too often assumed in the industry that if a given candidate for employment has no training, little education and appears good for nothing else, he should enter the sales organization. More careful selection of this sort of material could be exercised. It cannot be seriously maintained that our sales departments are today in general what we would like to have them. A reasonable length of time, if accompanied by genuine effort, will make them more profitable and helpful adjuncts of the utilities and a constructive force in the community.

Having raised the standard of requirement and performance in our sales departments, we shall have therein organizations specially trained in an understanding of the consumer and his desires, his dissatisfactions and state of mind—certainly a factor of great potentiality in accomplishing our desire for improved public relations. That such departments are not generally used for things which they presumably can best do is simply another way of stating that they are susceptible to substantial improvement, without depreciating the excellent work which they have accomplished in their previous development.

## Ontario May Start Peat Manufacture

THE solution of the fuel problem of the Province of Ontario through the erection of a government-owned peat plant is made in a report of a committee of the Provincial Legislature. The committee, which has completed researches occupying seven years, expresses itself as strongly of the opinion that the manufacture of fuel from Ontario's peat beds is a commercial possibility and should be considered.

## Electric-Steam Boilers in Western Sweden

THE use and employment of electricity for the generation of steam has been the subject of close study in Sweden for many years and has, United States Consul W. H. Sholes reports, to a certain extent been successfully realized in western Sweden, notably at Gothenburg and Vargon, especially during and immediately after the world war, when coal could be obtained only in insufficient quantities or at exorbitant prices.

The problem is chiefly of an economical character and of interest to countries either devoid of coal or endeavoring to eliminate it from their import budgets. The purely technical problems do not cause any difficulties; in fact, electric boilers, according to Swedish engineers, have proved to be simpler in construction, easier to build and erect than ordinary steam boilers, because fireplaces, smoke channels, smokestacks and fuel storage are unnecessary. Loss of heat by the smoke and gases escaping through the smokestack is avoided, it is claimed, and the loss of heat on account of radiation from an electric steam boiler can be reduced to such an extent that the working efficiency of the boiler can be brought up to 98 per cent, even if no more than 96 per cent can be counted upon in normal operation. Steam with working pressure can be raised within ten to twenty minutes.

Engineers in Sweden calculate that with a normal effect of 96 per cent about 825 caloric units are obtained per kilowatt-hour. The amount of heat required for generating 1 kg. of steam depends, however, on the temperature of the feed water as well as on the heat of the steam generated and the pressure to which it is subjected. Besides this, the price of coal as compared with the price of electrical energy must be taken into consideration, also continuous or interrupted use of electric power, the use of "surplus" electric power at night and on holidays and similar factors.

Local experience is that in electric generation of steam 1 kw-hr. can supplant 0.18 kg. of coal of average quality, and that therefore, with a coal price of 15 kronen ($4.02 at par) per ton, which was not unusual before the war, the cost of fuel for generating 1,000 kg. of steam will be 2.14 kronen ($0.574 at par). In order that the cost for the electrical energy per 1,000 kg. of steam generated in an electric boiler shall in this case be the same as the cost of fuel for the same amount of steam generated in an ordinary boiler, the price of energy must not exceed 0.27 öre (0.07236 cent) per kilowatt-hour. In Gothenburg the price is 15 öre. However, if the price of coal be 200 kronen ($53.60) per ton, which it was occasionally during the war, the equivalent price of electrical energy would be about 3.6 öre, and the cost of fuel or of the electrical energy would be 28.57 kronen ($7.66) per 1,000 kg. of steam.

For purpose of comparison, it may be mentioned, however, that the present price of coal in quantities is about 50 kronen ($8.04) per ton, and that the lowest ordinary price of second-hand converted electric power in the city of Gothenburg is 15 öre (4.02 cents) per kilowatt-hour. Therefore it is evident that first-hand alternating current direct from hydro-electric power stations can come into consideration only for the purpose under discussion.

Electrical energy in western Sweden is in many cases sold per kilowatt-year. In such cases the price of the electrical energy per kilowatt-hour is in an indirect proportion to the effective time of operation per annum.

# Letters from Our Readers

A Place Set Apart for Suggestions, Comments and Criticisms, to Which All Men of the Electrical Industry Are Cordially Invited to Contribute

## Cost of Selling Appliances

*To the Editors of the* ELECTRICAL WORLD:

Some two or three years ago the Electrical Contractors' Association sent out a questionnaire to its members and compiled some statistics which showed that the cost of handling electrical appliances amounted to about 35 per cent of the selling price. Inasmuch as several commodities, particularly washing machines, vacuum cleaners and ranges, which ran into a large figure did not carry on an average more than 25 per cent to a dealer, it was evident that there was no money in handling appliances from the contractor-dealer's standpoint.

The jobbers have also investigated this matter, but as jobbing experience is more or less varied between men who only receive and ship out in original packages and those who retail, I have no record of any definite figures being determined. I was at the contractors' meeting in Cincinnati where Mr. Gilchrist brought out the fact that central stations' contractor-dealers must get more of a "spread."

From our experience in appliances we know that the central station or the dealer that retails units such as washing machines, vacuum cleaners, ranges, refrigerating outfits and appliances of that type has a large expense bill in connection with demonstrating, trucking back and forth and then servicing the apparatus after it has been installed. We believe it is all right for central stations to exploit machines which require demonstration and a large amount of service, even though this may not show a profit, since the demand must be created and the experimental "try-out" with the public must be conducted by somebody and central stations are naturally better equipped financially to do this experimental work. But after the appliance has reached the condition that the vacuum cleaner, washing machine and range have reached today it should not be necessary to sell these goods at a loss, but the public will then be well enough acquainted with them to make the expense of exploitation unnecessary.

This is illustrated in the case of the flatiron. When the flatiron was first brought out it was necessary to allow a customer to try it out and experiment with it, which added to the selling cost. In fact, in the early years of the flatiron it was sold at a loss. Today the flatiron is recognized as a household commodity, and there should be no expense in connection with demonstrating or exploiting it. We believe, from our experience, that selling appliances such as flatirons, toasters, percolators, etc., can be handled at a smaller margin of profit than in the case of other types of machines.

I have looked into this situation from the department store's and furniture store's standpoint. I find as a general thing that department stores and furniture stores are not interested in handling large electrical appliances unless there is a spread of 50 per cent or more. I understand the usual spread in furniture is even higher than this. It would seem to me the only thing for us to do is to let the jobber, the central station and the contractor-dealer on the one hand get together and determine what is an equitable profit for handling these goods and then present this proposition to the manufacturer.

JOHN P. COGHLIN.

Worcester, Mass.

## Does Not Consider Absolute Elimination of Ionization Essential

*To the Editors of the* ELECTRICAL WORLD:

I have read with interest D. W. Roper's article on "Recent and Prospective Developments of Underground Cable." I agree with his statements with one exception —I do not feel sure that it is necessary to eliminate air ionization entirely as specified in the third paragraph from the end of his article. I know of a number of cables which have been in satisfactory service for several years in which ionization of occluded air undoubtedly occurs at operating voltages and has not been harmful in any way.

Mr. Roper is quite right in placing so much importance upon inspection at the factory. It will only be by very thorough control that it will be possible to obtain cables for voltages of 110,000. However, it is not only at the cable factories that this control is needed, but also at the factories of the paper makers and oil refiners.

WILLIAM A. DEL MAR,
Chief Engineer.

Habirshaw Electric Cable Company, Inc.,
Yonkers, N. Y.

## Ungrounded Lighting Fixtures Condemned as Unsafe

*To the Editors of the* ELECTRICAL WORLD:

I wish to register approval of the suggestion made by Fred Clayton in your issue of Dec. 20 last regarding the fusing of a grounded neutral. His idea of placing two fuses in series on a hot wire is very good in overcoming the objection that protection of only one fuse will be provided if the grounded wire is run continuously. There are serious doubts in my mind, however, whether this objection is justified considering the benefits derived from continuously wired ground. My personal opinion is that the use of one fuse to protect a circuit meets with objection simply because it is not the way we are accustomed to doing things. In other words, the use of one fuse to protect a circuit must overcome the inertia of the old methods with their historical backgrounds.

Along this same line, the writer cannot understand why agitation has not been brought to bear in the past against the use of ungrounded electric lighting fixtures. While death from lighting voltages occurs rarely, nevertheless a few instances are known to the writer where death would have been prevented had the fixtures been grounded as is done in the case of motor frames. This, perhaps, would create a little additional fire hazard, but I think it is high time that the value of human life as well as the value of property should be considered.

It is the writer's personal opinion that the frame of every electrical device, whether it be motor, transformer, electric light fixture or what, should be securely grounded and that the neutral of lighting circuits should be grounded and run continuously without fuse from transformer to end of circuit. This practice would result in uniformly safe installation.

# Central Station and Industrial Practice

Installation, Operation, Maintenance, Test and Repair of Generation and Distribution Equipment, and Methods of Economically Utilizing Electric Service in Large Industrial Plants

## Testing Relays Prior to Installation

**Checking Correctness of Operation Before Placing Apparatus in Service—An Account of Particular Interest to Small Companies Unfamiliar with This Work**

THE relays which are provided throughout an electrical generating and distribution system are far more important than would appear on first thought as the continuity of service of a part of a system or even an entire system depends upon the correct functioning of such relays. Too much stress, therefore, cannot be laid upon the care which should be used, first, in selecting the proper types of relays; second, in inspecting and checking them at the time of placing them in service, and, third, in maintaining a rigorous routine inspection and calibration. The failure of relays to isolate a piece of equipment at the time of the occurrence of a fault may lead to serious damage which would not be caused if the equipment were removed from the system instantly.

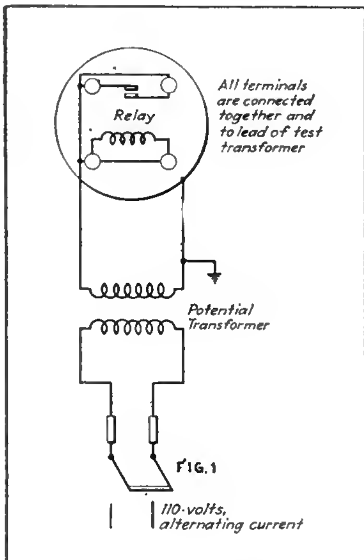
It is intended in the following discussion to cover the most important points that should be taken care of in the inspection of relays when they are received prior to placing them in service, but not to touch on those comparative tests which should be made on a number of relays at the time a choice is made of the particular type to be used.

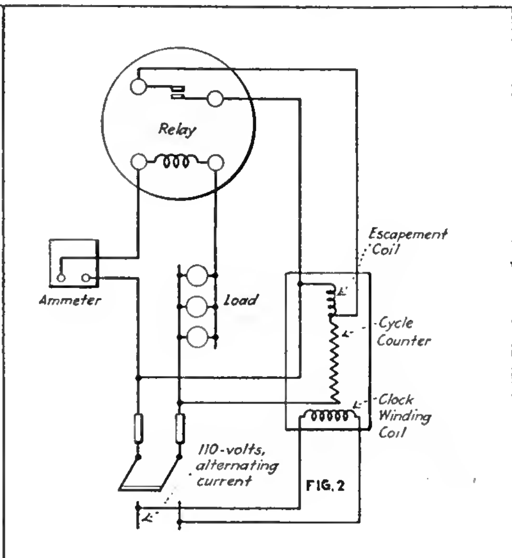
All relays when received should be inspected very carefully to make sure that there is no foreign material in them and that no breakage has occurred since leaving the factory. All moving parts, such as plungers, disks, etc., should be examined to make sure that they move freely throughout the entire range. It is also important to see that all contacts close and open properly and that no parts have worked loose.

Potential tests (about 1,000 volts) should be made on the windings and contact systems of the various relays to make sure of good insulation and clearance. Typical connections for this test are shown in Fig. 1.

Most excess-current relays have time adjustments and should be checked for operating current and time at several points, one of which should be the minimum operating current and another a current large enough to cause the relay to operate on the flat part of its characteristic curve. A cycle counter will be most convenient to measure the time, and the general scheme of connections can be as given in Fig. 2. Usually there are characteristic curves furnished with the relays which should be compared with these test data and used later for setting the relays when installed.

Power directional relays, in addition to being inspected as outlined above, should be connected to a test circuit in the laboratory to make sure that the leads are brought out properly so that the tripping contact will close on the proper direction of energy transfer. Fig. 3 shows the connections for making this check on Westinghouse type CR relays. The General Electric type IK relay can be tested in the same manner with slightly different connections. The adjustment of the power directional relay must be very carefully made as in case of line failure the voltage is much reduced and with this low voltage on the potential coil comparatively little torque is pro-





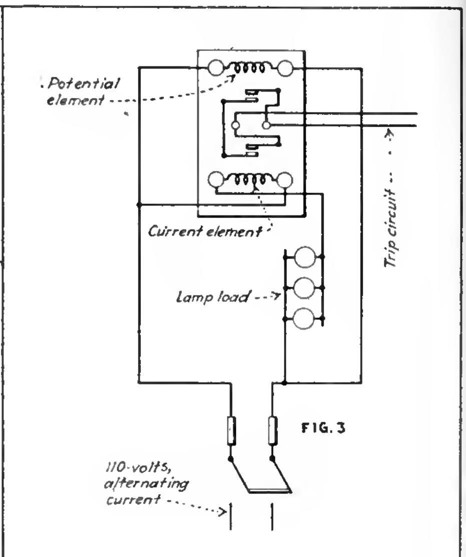


FIG. 1—TESTING INSULATION OF RELAY WINDINGS AND CONTACT SYSTEM. FIG. 2—CONNECTIONS FOR TESTING EXCESS-CURRENT TIME-LIMIT RELAYS. FIG. 3—TRIPPING CONTACTS SHOULD CLOSE WHEN TESTING WESTINGHOUSE TYPE CR REVERSE POWER RELAYS USING THESE CONNECTIONS

duced. If not carefully adjusted, it is possible under the condition of low voltage that the operation of the directional relay may require more time than with the excess-current relay which is properly set in conjunction with other relays on the system and thus destroy selective action. The excess-current relay used with power directional relays may or may not be in the same case with them, but in any event should be tested as outlined above.

Single-winding differential relays are to all intents and purposes instantaneous excess-current relays and should be inspected carefully and checked for operating current.

In later issues comments will be given on the checking of relay installations prior to placing them in service and on routine testing and calibration of relays.

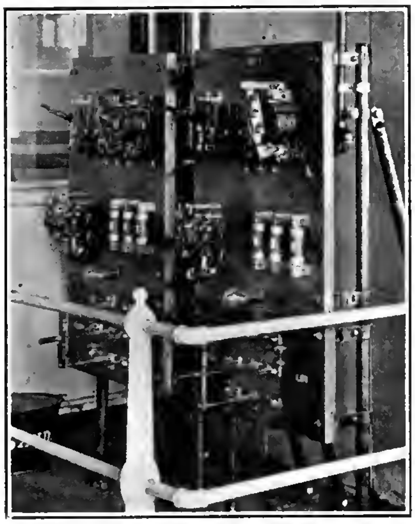
RAYMOND BAILEY,
Assistant Chief Electrical Designer.
Philadelphia Electric Company,
Philadelphia, Pa.

## Electric Japanning Ovens for Optical Company

TWO batteries of electrically heated japanning ovens are now operating in the Bausch & Lomb Optical Company's factory at Rochester, N. Y., and the company's experience with them is interesting both because of the character of the work done and the results obtained. The material baked comprises not only high-grade japan, but rubber enamels and bakelite, and the finished parts are used in the assembly of microscopes, field glasses and other instruments where the quality of the finish is of paramount importance. The effect of electric heat on the quality of the finished articles and upon the over-all production cost, under these exacting conditions, should be of interest to those with similar problems to overcome. Since the ovens have been installed the percentage of parts rejected because of improper baking has been reduced to about 4 per cent of the total amount baked, as compared with about 50 per cent with the gas ovens formerly used for the same purpose.

The total installation of ovens comprises two truck-type and three shelf-type units, both types having a connected load of 36 kw. each in heaters, or a total of 180 kw. at 230 volts, three-phase, 60 cycles.

The two box-type ovens are installed in one end of a small room, the rest of which contains the spray hoods, trucks, etc. Each oven is 5 ft. wide by 6 ft. 6 in. deep by 6 ft. 9 in. high. They are of the box type built by Young Brothers of Detroit. The heaters are installed in two banks, on each side of the ovens, extending from front to back, about half way up the walls. The control is automatic. The two automatic control panels, furnished by the General Electric Company, are installed together at one end of the ovens and carry the necessary contractors, pilot lights, overload relays and a double-pole, double-throw switch on each panel for changing the heater connections from Y to delta to obtain high or low heat. The temperature range is between 300 deg. F. and 450 deg. F.



CONTROL APPARATUS FOR ELECTRIC OVENS

The shelf type ovens are mounted along the side wall of another room, which is also used as a spraying room. The baking space of these ovens are each 3 ft. 4 in. wide by 2 ft. 5 in. high by 3 ft. deep. The heaters are installed between the bottom of the lower baking compartment and the floor level of the room. These ovens are also automatically controlled. The automatic control panel for each oven is mounted directly above the oven itself, while the instruments are mounted on the rear of the ovens.

FEWER REJECTIONS AND GREATER SPEED IN BAKING ARE ADVANTAGES OF ELECTRIC OVENS

The most interesting feature of the installation, however, is the effect the ovens have had upon production as regards both economy and volume. The parts must have an exceptionally high quality of finish owing to the uses to which they are put. This may be elaborated by saying that these finishes must be duplicated time after time on a large number of different parts, as these are baked in large numbers and then returned to stock for assembly later. The effect of a number of parts with varying degrees of finish assembled together on the same microscope, for instance, need not be emphasized.

### STRICT TEMPERATURE CONTROL IMPORTANT FACTOR

The ability to control the temperature of the ovens accurately makes this duplication of results possible, as the degree of finish is determined by the temperature of baking. Furthermore, the absence of contaminating gases in the oven interior is an important factor in decreasing spoilage.

This same freedom from contamination, which extends to the atmosphere surrounding the ovens, makes it possible to put the spraying machines in the same room, which naturally saves much time and labor in handling the material to be baked. Since articles can be baked much more rapidly owing to the higher temperatures possible with electric heat, the time of baking per load has been reduced from about five hours with gas ovens to about one and one-half hours with electric ovens, at temperatures of from 300 deg F. to 450 deg. F. according to the finish desired. To sum up the matter, the economy of the electric oven has been found to exceed that of the gas oven because of fewer rejections, greater speed in baking and the saving in space, labor and material that can be directly traced to its use.

Factory Engineer.
Bausch & Lomb Optical Company,
Rochester, N. Y.

COMBINATION OF BELT CONVEYOR AND BOX-CAR LOADER UTILIZED IN JAPANESE POWER PLANT TO HANDLE COAL

## Coal-Conveying System in Japan

THE installation of an American-built belt conveyor and a box-car loader at the gas works in Kobe, Japan, proves that the efficiency of this method permits it to compete with the cheap labor obtainable in Japan. This plant operates with slack coal. The combination of a belt conveyor and a box-car loader, as illustrated, makes for very flexible operation in handling coal. The loader has been developed to deliver sand and other materials to the farthest corner of a box car without the machine itself taking up much room; but Japanese engineers have used this loader in conjunction with a standard belt conveyor so that still more efficient operation is obtained. This information was obtained from the Link-Belt Company, Chicago.

## Gravity Pipe Line Saves 150 Kw.-Hr. a Day

BY BUILDING a new condensing-water intake line from the Concord River to a cold well outside the local 1,200-kw. municipal lighting plant located at Concord, Mass., it was found that 150 kw.-hr. a day could be saved which had formerly been consumed in operating a motor-driven centrifugal pump. Formerly a 7.5-hp., 200-volt, two-phase vertical motor in a pump house near the river ran a pump which lifted the water about 8 ft. and delivered it to the plant through a 12-in. pipe 600 ft. long. The new line of 18-in. wooden staves enables gravity flow to be obtained from the river, the length of the line being about 620 ft. On account of quicksand and other poor foundation conditions, the cost of the new line with intake-screen connections, etc., was about $6,600, but at a conservative figure for the energy consumed by the pumping outfit, the investment will be retired in a reasonable time by the change, besides giving a more reliable service. The former pipe line and pumping outfit are held in reserve.

FIELD EDITOR ELECTRICAL WORLD.
Boston, Mass.

## Reversal of Meter Torque at Low Power Factors

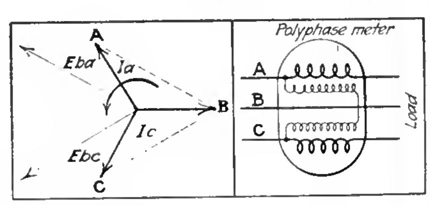
OCCASIONS often arise when it is desired to determine which element of a three-phase watt-hour meter is exerting a backward torque under conditions of lagging power factors below 50 per cent. This condition is easily ascertained if a small highly inductive load, such as a motor lightly loaded or running idle, can be put on the line and the potential circuits of the meter alternately opened. However, such opportunity is not always available, in which case it is convenient to determine the phase sequence at the meter, thus indicating which is the reversing element, as explained below.

A tester usually has as a part of his testing equipment the necessary apparatus to determine the phase sequence or rotation. A very common method is to connect two 25-watt or 40-watt, 110-volt lamps and the 110-volt primary of the phantom loading transformer or the 110-volt potential coil of the rotating standard in star connection to the three-phase line. Then if *A, B* and *C* represent the phase rotation, as shown in the accompanying illustration, line *A* should be the one connected to coil, line *B* the one connected to the dim lamp and line *C* the one connected to the bright lamp. A telephone condenser rated at 1 mfd. might be used in place of the coil and the order would be reversed.

If the upper element of a meter reverses at low lagging power factors, it is found that the lower element will be the reversing one if two of the line wires ahead of the meter are interchanged, causing the phase rotation to be reversed. It is thus apparent that there is a definite relation between phase rotation and the question of which of the elements will reverse in direction of torque exerted on the meter disk when the power factor of the load is lagging and below 50 per cent.

A study of the vector diagram will show that if phase rotation is indicated by *A, B* and *C,* the current coil of the reversing element will be in line *A*; the line *B* will be the one common to both potential coils, while the current coil of the element always running forward will be in line *C*.

Referring to the diagram and assuming a balanced load, vectors $I_a$ and $I_c$ represent the current in the two current coils in phase relation (under conditions of unity power factor) to the vectors $E_{ba}$ and $E_{bc}$, representing the voltage across the potential coils of the upper and lower elements respectively. The vector rotating in the direction indicated by the arrow, it is evident that as the current lags behind the voltage, due to inductive condition of the load, the voltage vectors $E_{ba}$ and



REVERSAL OF METER TORQUE ON INDUCTION MOTOR LOAD STUDIED BY USE OF VECTOR DIAGRAM

$E_{bc}$ will advance ahead of their respective current vectors, $I_a$ and $I_c$. Now, since the voltage vector $E_{ba}$ of the upper element is already (at unity power factor) 30 deg. ahead of its current vector $I_a$, while the voltage vector $E_{ba}$ of the lower element is, under the same condition, 30 deg. behind its current vector, it is shown that the voltage vector $E_{ba}$ of the upper element will become 90 deg. ahead of its current vector first.

Any further separation of the voltage and current will cause reversed torque on the meter disk by the upper element.

## Standard Nomenclature for Oil Circuit Breakers

A NUMBER of definitions covering standard nomenclature for oil circuit breakers were adopted by the Electric Power Club at its regular fall meeting held at Asheville, N. C. These should greatly assist in furthering clarity in specifications. A partial list of the definitions is given below.

*Accessories* — To be used broadly to include both attachments and auxiliaries.

*Attachments* — Accessories to be attached to a circuit breaker as distinguished from auxiliaries.

*Auxiliaries* — Accessories to be used with circuit breakers but not attached to them, as distinguished from attachments.

*Automatic Trip*—Operation of a circuit-opening device due to changes in current or voltage or other electrical conditions without requiring manual control. Automatic operation may be obtained by the use of any one of the following devices: (a) Self-contained overload trip connected to current transformers with or without relays; (b) shunt trip energized through relays operated by current or potential transformers; (c) self-contained series trip directly connected in the circuit; (d) under-voltage trip with or without potential transformers.

*Baffle (Deflector)* — Device for deflecting oil or gas.

*Barrier*—Partition for insulation or isolation of electric circuits or arcs.

*Bell Alarm Switch* — A switch controlled by the automatic opening of a circuit breaker and designed to close the circuit to a bell or other audible signaling device.

*Bell Crank* — A rectangular lever by which the direction of motion is changed through an angle.

*Bushing* — The part insulating a through conductor.

*Calibration* — A set of graduations marked to indicate the values of current or voltage at which an automatic trip device can be set to operate.

*Cell*—A compartment to isolate circuit breakers or other switching equipment.

*Cell Doors* — Doors for closing the front or rear of a cell.

*Cell Structure* — A set of compartments to house switching equipment.

*Clevis*—A fitting having a U-shaped end and arranged for attaching to the end of a pipe or rod.

*Fume Resisting* — Fume-resisting switching and control apparatus is apparatus so constructed that it will not be readily injured by the specified fumes.

*Pipe End (Rod End)* — A fitting arranged to connect the end of a pipe or rod to a lever, bell crank or other part.

ROTATING ARM HOLDING GLOVES IN TESTING EQUIPMENT SAVES TIME

## Time to Test Rubber Gloves Cut 60 per Cent

THE number of rubber gloves which must be tested regularly is often considerable, and labor-saving methods are very helpful in this work. During the first half of 1922 an average of more than 550 gloves a month was tested at the laboratory of the Edison Electric Illuminating Company of Boston, and the time per pair has been cut from about five minutes to about two minutes by co-ordinating the equipment and methods used. The test for leakage follows well-known lines, the safe limiting value of leakage current being set at 10 milliamperes at 10,000 volts. The basis of this reduction in time is a rotating holder devised by a member of the laboratory staff and illustrated herewith.

The customary tank for glove testing is in this case large enough to permit testing ten gloves at once. The tank is equipped with a swinging arm carrying ten individual metal glove holders, and the arm can be moved through 90 deg. by means of an external handle. In testing, the arm is swung above the surface of the water so that the glove holders are brought into a horizontal position as shown. The gloves are inserted in the holders, and the arm is swung back into the water, the end of its travel bringing the gloves into a vertical position in the water, which rises to within about 2 in. of the edge of the cuff. Water is introduced into the gloves one by one through a rubber hose with convenient valve above the group. Above each glove on a wooden bar is a binding post with chain for use as an electrode within the glove, each chain being wired to an insulated push button on a control switchboard. One side of these buttons is grounded, voltage being applied between ground and the metal tank. A milliammeter is so arranged that pushing any particular button causes the leakage current of the corresponding glove to be indicated on the instrument. This arrangement enables the leakage current of ten gloves to be readily observed within the required sixty seconds' time limit of the test. After testing, the rotation of the arm to the horizontal position automatically empties the gloves.

Edison Electric Illuminating Company,
Boston, Mass.

## Synchronous Motors for Industrial Drives

THE method of synchronizing a motor while on the starting tap at low voltage and then throwing over to full-line voltage was advocated by S. H. Mortensen in a paper on "Self-Starting Synchronous Motors and Their Application to Power-Factor Correction and Industrial Drives," presented before the A. I. E. E. section of the Western Society of Engineers on Jan. 15. He illustrated this point by showing the two "V" curves for a synchronous motor, one for half voltage and the other for full voltage. It was preferable to synchronize where these two curves cross each other rather than at the bottom of the curve, which would give rise to excessive armature current under full voltage.

Regarding the application for industrial drives, Mr. Mortensen listed

three things which were essential before any changes were made, namely, first to examine the details of the cable system from power stations with respect to the inductance of these lines; second, not to have the drive overmotored; third, consideration of the replacement of three or four small motors by one large-size motor.

Mr. Mortensen declared that synchronous motors for industrial purposes were now obtainable from 35 hp. up to 5,000 kva. The full-load losses of the last-named machine with proper design, he declared, would be only about 100 kva., with the no-load loss 50 kva. With regard to reciprocating loads such as air and ammonia compressors, care must be taken to keep the forced frequency of the load and the natural frequency of the motor at least 20 per cent apart, as otherwise the forced frequency will magnify the rotor swing and cause fluctuations in power input to the motor. The permissible value of the swing depends upon the relative capacity of the power feeder and the constants of the motor, but most compressor motors in successful operation limit this swing to approximately 60 per cent of the current fluctuation.

## Firing and Putting Boilers on the Line

BEFORE starting up a boiler and placing it on the line the steam-pressure gage and water column should be carefully inspected, the section of pipe between the main stop and automatic non-return valve should be drained and trap lines should be used to drain the condensate from the steam piping and prime movers. When the condensate from the steam piping and prime movers is not drained damage is often caused. Water should be turned on to the waterbacks before the fire is started, otherwise the waterbacks will become so hot that they will be cracked when cold water enters. At first raw water should be used to prevent taking too much condensate from other boilers.

Below are listed the directions for starting up a boiler and putting it on the line as abstracted from the operating code of the Philadelphia Electric Company:

PUTTING A BOILER ON THE LINE

1. Remove danger signs from main stop, main feed, blow-off valves and control board.
2. See that blow-off valves are all closed. Where a safety stop gate valve is connected to blow-off line see that this valve is open.
3. Open all vent valves.
4. Close all drain valves.
5. See that valves controlling water column and pressure gages are in operating condition and open.
6. Open the water-feed valves to the boilers slowly for one or two turns. On boilers equipped with separate economizers see that the valves between the boilers and economizers are open.
7. Fill the boiler to about one gage.
8. Open the superheater drains.
9. Start the stoker and fill the grate about half way down with coal.
10. See that the change-over valve on the waterback lines is set for raw water.
11. Open the feed and discharge valves on the waterbacks.
12. See that "telltales" are open and discharging water and that the drains are clear.
13. Turn on the spray of the clinker crusher pit.
14. Open the stack damper.
15. Dig holes in the coal over the tuyères and put a shovelful of fire in each hole or use wood and oil-soaked waste.
16. Cover the fire with "green" coal.
17. Start both the induced and the forced draft fans slowly. Have the electrician inspect the motor-driven forced and induced draft fans before starting.
18. Adjust the stack damper to proper draft over the fire.
19. Apply proper blast on the forced draft.
20. Close all vents on the boiler as soon as steam escapes.
21. Note that the pressure gage is operating.
22. Raise from 30 lb. to 50 lb. pressure on the boiler.
23. Close the drain valves on the superheater. These valves may be left cracked until the boiler is about to go on the line.
24. Increase the speed of the fans for both induced and forced draft to such a degree as may be required.
25. Bring the boiler gage pressure up to from 150 lb. to 180 lb.
26. See that the drain valves between the main and automatic non-return valves are open.
27. Open the by-pass valve of the main stop-valve and blow out all water from the gooseneck between the automatic non-return valve and the main stop valve.
28. Close the drain valves.
29. Open the trap line valve above the automatic non-return valve.
30. Open the main stop valve and close the by-pass on the same.
31. Unlock the automatic non-return valve when pressure has risen to within 50 per cent of the line pressure.
32. Increase the stoker speed and air blast until the boiler begins to steam. Keep the fire as light as possible. The rate of increasing the blast and stoker speed is determined by how fast the boiler must be put on the line.
33. Set the change-over valve on the waterback line for condensate.
34. Inspect all boiler-setting doors and see that they are tightly closed.
35. Blow down both water columns to check the water level.

## Inspection of Rotating Electric Machines

GOOD electrical contact between brushes and commutator or slip rings is essential to prevent sparking and excessive heating. This can easily be obtained if the brushes are clean, free in the holder and under the proper spring tension and can, therefore, accommodate themselves to the surface of the commutator or slip rings. Very serious mechanical or electrical damage may sometimes be caused by small objects, such as bolts, nuts and screws left on or near a machine, which may be shaken down by vibration or drawn in by magnetic force. In the operation of all machinery one of the most important points to observe is to see that oil is properly fed to the bearings.

The acquiring of systematic habits in practice will go far toward preventing trouble and accidents, and the following rules abstracted from the operating code of the Philadelphia Electric Company should be of value:

INSPECTION BEFORE STARTING

1. Go over the machine carefully, inspecting alternating-current and direct-current brushes. See that they move freely in the holders, that they fit closely to the commutators and slip rings, that all connections are tight between brush holders, shunts and brushes, and that on rotary converters provided with brush-lifting devices the direct-current brushes, except the pilot brushes, are lifted off the commutator.
2. Examine all speed-limit devices and see that they are in proper operating condition.
3. Wipe off commutator, slip rings and brushes.
4. Examine the interior of the machine for foreign material and for visible damage to the insulation.
5. Remove all bolts, tools and foreign material which may have been left lying near the frame.
6. Examine bearing housings to make sure that there is the correct amount of oil in the wells and that the rings are free to turn.
7. Examine all switches to see that they are in proper position for starting.

INSPECTION AFTER STARTING

Immediately after starting and before putting on load examine all oil rings to make sure that they are turning over and carrying oil.

## Simplified Rates a Good-Will Asset*

**Complex Schedules Irritate the Majority of Residential and Small-Power Customers—Specific Instances—The Question of Discounts**

BY A. S. PRATT
District Manager Stone & Webster, Inc., Boston

THE small house owner, the fellow who pays rent and the one who just lodges are quite fond of thinking of themselves as being more or less the "downtrodden" victims of the big business concerns and financial institutions on the street. When we enter upon a discussion of public relations these men come into their own, for they constitute the one important factor to be considered. In so far as the public utility is concerned, the financial and business sentiment of a city is likely to be relatively unimportant—if, in fact, it is not already sympathetic because of its better understanding of big business—but the chap who is so gleefully pictured by the "reform" newspapers as of the "common peepul" is the man whose tolerance and consideration we must win. And so our most important field for missionary work is that occupied by the residence lighting user and the small power consumer.

For a number of years the national associations and many companies have directed a very earnest and expensive campaign toward teaching the housewife and her husband the significance of a kilowatt-hour, and some even more optimistic and ambitious crusaders have still further refined their educational program by dilating upon the advantages of comprehending a watt. Possibly the progress made by those who have labored so long and heroically along this line has been satisfactory, but we might pause and ask "What of it?" What particular advantage is it to us for Mrs. Jones to know what a kilowatt is? She doesn't buy kilowatts and she doesn't use them. She does buy heat and light. Perhaps all of this is of no importance except to illustrate the angle from which a great industry may approach a desired objective. Apparently it has thought it necessary to force upon Mrs. Jones its own arbitrary terms rather than to permit her to be happy and contented in the use of her own. In any event it has not been notably successful. In the beginning it would have been far easier to have fitted our performance into the customer's requirements and mental state than has been the attempt to force him to fit his to our own.

### SOME RATES TOO COMPLEX

Some of the industry's rates are too complex. No doubt the various factors which enter into them are justified from the engineer's viewpoint, but the fruit grower who sought to sell peaches to the housewife at so much for the first "gazook" plus a service charge plus a charge because she didn't buy last week plus a half-dozen other factors of which she knows nothing and whose real existence she doesn't concede would carry his peaches home with him when the day came to a close.

Probably our busines is not so simple as selling peaches, but we might find it profitable to make it as nearly so as possible. Any rate other than a perfectly simple one contains elements of mystery to the consumer, and any human being is suspicious of anything he cannot understand. Perhaps much thought could be profitably expended in contriving simple rates which will bring in the revenue. that a scientific analysis of conditions determines necessary, but which will be expressed in more or less general terms.

Not long ago a central-station company had occasion to seek an increase in its lighting rates before a city council. The rate expressed its intentions in the ordinary electrical nomenclature. The people were willing that an increase of some sort should be established, but would not accept the one proposed. After much fruitless negotiation and delay a committee of customers came before the city council with a rate schedule which it had prepared and which it was willing should be established. The company accepted it. It was a slightly higher rate than the company had proposed, but it was expressed in a manner that everybody could understand and every one was satisfied.

In a Western city the public became very much worked up over a lighting rate of 9 cents per kilowatt-hour which was locally in use. The agitation following a city election resulted in a situation where the city undertook to do its own retailing, purchasing energy from the old company at approximately 2 cents per kilowatt-hour. Under city management the ostensible rate became 3 cents, but it started off with a flat annual charge varying from $20 to $50. Actually it works out that the people are paying in the vicinity of 11 cents per kilowatt-hour but they are perfectly happy. The figure which really sticks in their minds is the 3 cents, and they appear able to forget the flat advance charge. Incidentally, the company is more prosperous than formerly, so every one is satisfied. Almost any resident of this city will descant upon how much cheaper lighting is than formerly.

Another company changed from the usual rate structure to one wherein cubic-foot content of used rooms is apparently the principal factor, and by so doing slightly raised its rates. This broke the back of an agitation for lower rates which threatened the utility's occupation of its field. This rate was actually more complex than the one it replaced, but it had the merit of being expressed in familiar terms. There are in existence in not a few com-

*From an address before managers of Stone & Webster properties.

panies small-power rates which are so complicated that it would embarass many managers if they were asked to interpret them without prolonged study. Such a rate cannot possibly have an effect on the customer other than to weaken his confidence in the utility. He can never feel sure that he is paying only for that which he has used.

Large-power rates do not have the same effect on public relations as do the small-power tariffs.

A discount for a prompt payment of a bill is not a discount in any sense of the word. It is a roundabout and legal way of imposing a penalty for delayed payment. One of its disadvantages is that it is the gross rate and not the net which is fixed in the public mind when any discussion of rates is before it. One company has, for example, a gross rate of 10 cents for lighting, with a prompt payment discount of 25 per cent. Therefore the net rate is $7\frac{1}{2}$ cents. Yet customers do not think of the rate as being the latter figure; it is always 10 cents in newspapers and elsewhere.

#### Abolishing Discounts

Some interesting experiments are being made in abolishing discounts. One company did this and in this way obtained a "chocolate-coated" rate increase. Of two others which have tried it, one reports that the change has made no material difference in collections, while the accounting department of the other questions the wisdom of the change while volunteering the information that collections appear to be pretty good so far. The advantage is that the abolition of the discount will make the rate appear to be lower and the consumer who fails to pay his bill on time is not penalized, as he generally believes, unjustly.

## Dayton Company Rescues Municipal Plant

TROY, Ohio, has a municipal electric light plant and this plant has had more than its share of troubles. It has in the past few years encountered everything from inadequate equipment to internal dissension, and the citizens of Troy have suffered and lost money.

Recently the new plant which the municipality had been trying to make go this year gave up and quit. The system of the city of Piqua is owned by the Dayton Power & Light Company, and A. J. Patrick, the superintendent at that place, learned of the neighboring city being in darkness and communicated with the Dayton office to know whether it could help Troy out. O. H. Hutchings, general manager of the Dayton company, made the connection in a few hours by installing two 500-kw. transformers, building a line and stringing wires, crossing a railroad right-of-way underground with 33,000-volt conductors and building an outdoor substation and connection in Troy.

The city of Troy has spent approximately $300,000 on a plant, and the whole undertaking now appears to be a sorry mess.

# The Banker's Side of Customer Ownership

### Co-operation Between the Utility Company and Local Banks in Public Offerings of Securities Develops Good Will and Makes Financing Easier

WITH the increasing sale of public service company stock to customers and residents of the community served the attitude of local bankers is frequently a matter of concern to utility executives. At times the banker has looked somewhat askance at a customer-ownership campaign, for he felt that the utility company was encroaching too much upon his field. Again, when a drive for the sale of stock got under full swing, depositors have made rather heavy withdrawals from their bank accounts to purchase the stock, which, in the aggregate, temporarily disturbed the equilibrium of the banks' cash deposits. As a matter of fact, customer-ownership has always proved beneficial to the community by keeping investment money at home and forestalling wildcat speculation, encouraging thrift and, in the long run, increasing the deposits and business of the local financial institutions.

Most bankers, however, are far-sighted and therefore eager to cooperate with a company in customer ownership. They feel, and rightly, that they have a vital interest in every industry and business project of the community. The bankers' viewpoint was set forth in a most interesting manner by Robert Neill, vice-president of the Hot Springs National Bank, at the convention of the Arkansas Public Utilities Association in that city on Nov. 7-9. His statements are particularly pertinent and merit serious consideration by central-station officials when laying out a program and preparing the ground for the sale of securities locally. Pointing out that the local utility stock is a logical form of investment for its customers, Mr. Neill said:

The discriminating public, while not always capable of analyzing balance sheets and earning statements, is inclined to invest in the things it knows something of, or at least of which it thinks it knows something, and it seems to me therefore that those concerns which serve the necessities of our every-day lives in these modern times come most readily to the minds of people who have a surplus and are looking around for a suitable investment. With our vanishing supply of firewood and bad labor conditions holding back coal production, gas and electricity are the only dependable sources of heat and light, and in this day, when rapid transportation facilities are imperative, I class these with food and raiment as our first necessities. You who are in the business of bringing these supplies to your respective communities should receive your public's first consideration when you have something to offer in the way of investment.

The theory of profit sharing with employees in vogue in many of the industrial and manufacturing establishments of the country had its inception in the desire of the employer to get the benefit of a psychic feeling in the minds of his workmen that they were partners in his business. The same rule, broadened somewhat, is workable with the public you serve. Give them an opportunity of investing in your company to some extent, and they will have a personal interest in the well being of that company and assist in molding a favorable public sentiment toward your enterprise and organization.

#### Let the Banks Join in Selling Stock

Some of the largest stock issues of recent times have been disposed of on this plan, and in its ramifications the local banker should not be overlooked, for he helped finance all your projects at some stage of their development and perhaps took a chance with some of you which led to your success. The bank, as a rule, expects to be the custodian or depository for the funds of its public only for that period when a profitable investment may not be had, except, of course, as regards its active commercial accounts and those who are satisfied with the comparatively low returns of savings-bank interest. There is, however, a very comfortable proportion of the average bank's funds made up of deposits which are comparatively inactive, and these are the bulwark of the bank and its earning capacity.

When a utility corporation sets under way a program of permanent, or even temporary, financing in a public offering, that offering makes an appeal to the owner of this inactive bank account.

who proceeds to invest, sometimes seeking the advice of his banker and at others giving his check without explanation or comment. When your country banker sees his deposits going out in this channel it makes an impression. Therefore, I say that the course of some corporations which had stock issues to market of first interviewing local bankers and securing their co-operation in making sales, even at the expense of allowing a small brokerage, discloses good judgment. This is giving some measure of recompense for the banker's loss and is worth the cost to the corporation in good will. That may sound like the devil's theory that every man has his price, though I do not consider it so, for we all like to feel that we are getting an even break in all our business and commercial dealings.

Branch banking is rather irrelevant to the subject, but at this point it seems apropos to say that the individual, locally owned banking organization has been the cause of the rapid development of this big country of ours, and while no doubt this argument of centralized power, consequently cheaper power, applies logically to your line of business, I submit that it does not to mine. I confidently believe that a banking institution controlled and officered by individual residents in and conversant with their locality can much better serve that community than could the branch of some large bank operated by executives at a distant point who are not in sympathy, perhaps, with local plans and ambitions. The enlargement in the amount of money under the control of such an organization would not necessarily mean cheaper money, the probability being that your locally controlled bank would loan for local purposes more liberally in amount and rate than would its big rival.

What chance would a local utility have in securing help and co-operation in a local flotation of securities with a branch office of a non-resident banking institution? This is the application of branch banking to the subject in hand.

### An Endless Chain of Prosperity

Any increase in the income of your utility due to legitimate causes means an increase in the banking business in your town. If you have to lay new mains or build new lines to serve new patrons in a new district, that means so many more people to earn and spend with your merchants and to deposit in your banks. An increase in power sales means another industry started which will furnish employment to more men to earn money to put in channels of trade, whence it gravitates to the banks.

It is an endless chain. The more general prosperity the more prosperous is the bank serving this community, for the bank which does serve its community makes its loans in such lines as will tend to build up and increase business and population, and it usually takes its losses with its community when business goes wrong and periods of depression set in.

Harmonious co-operation of component parts is necessary to make a smooth-running machine of any kind, and the banking interest is perhaps in the same boat with the public utility interest in that we are neither to be classed primarily as producers and are not therefore indispensable; for you know there was a time when there were no banks and folks carried their money in belts and there was a time when you had to use a pine torch or a tallow candle to make your way afoot to the stream where you quenched your thirst or took your bath. But who wants to live in those times again?

Having this community of interest, therefore, I believe even closer co-operation between banking and utility lines will be mutually advantageous, it being perhaps possible to reach the condition where financing will be done through your banker rather than through your broker or underwriter.

## Good-Service Publicity Bears Fruit

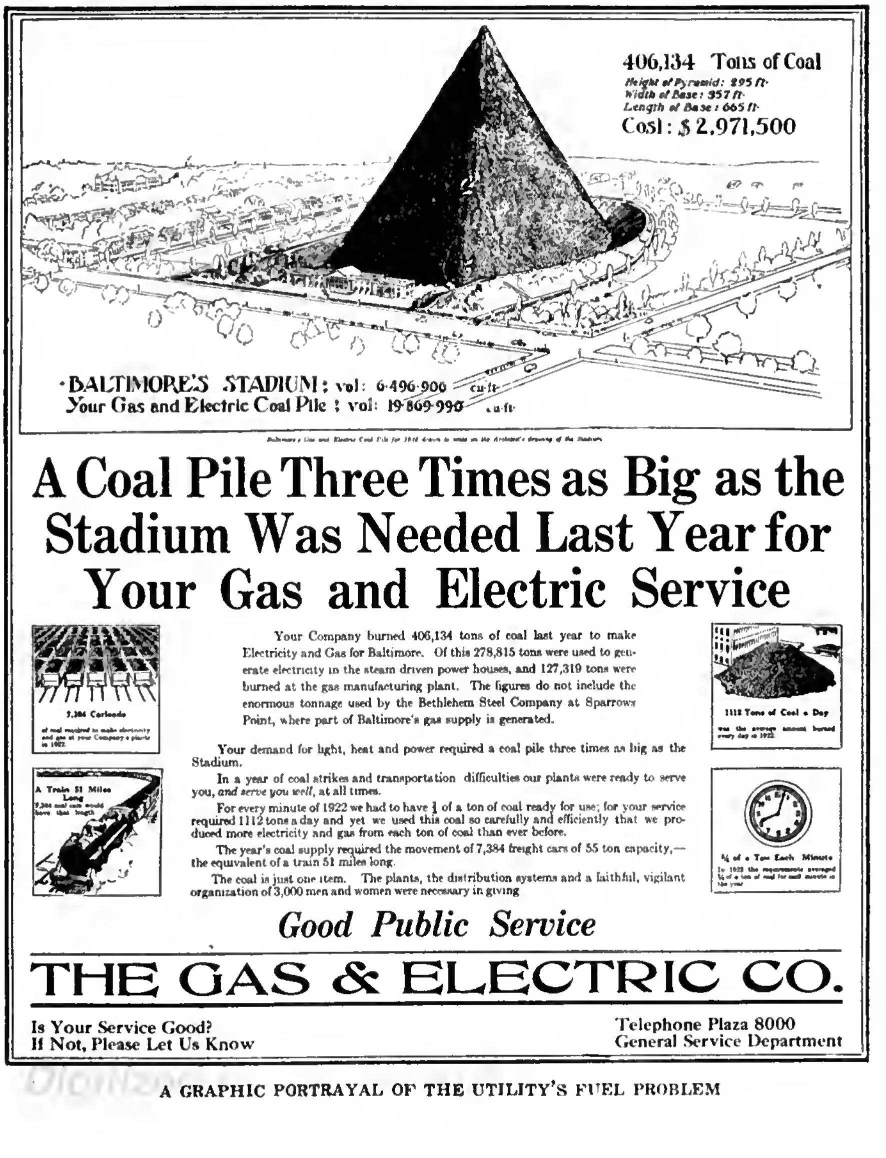
As a MEANS of acquainting its customers and the public with the different phases of the work required to maintain a high standard of service, the Consolidated Gas, Electric Light & Power Company of Baltimore has for some time been running full-page advertisements which illustrate and explain many outstanding features about the company. One of the most interesting of the series, one which is particularly timely during the present coal stringency, is shown here. It gives a graphic picture of the company's fuel problem and visualizes to the public the magnitude of its operations.

All of the advertisements are written around the slogan "Good public service," and each carries the inquiry, "Is your service good? If not, please let us know." A most gratifying response to this effort to improve the service is seen in a letter from a customer which was published as one of the advertisements after the customer's permission had been obtained. Under the caption "One of Our Customers Writes a Public Service Advertisement" the letter read:

*The Gas & Electric Company:*

Gentlemen: Two men were discussing the series of "Good Public Service" advertisements now being published by the Gas & Electric Company. The suggestion was made that in covering the larger aspects of service the little items be not overlooked.

It is, of course, right to talk about the wonderful electric turbines on the Susquehanna and the high-power cable transmission line that brings the energy to Baltimore, but all this great equip-



A GRAPHIC PORTRAYAL OF THE UTILITY'S FUEL PROBLEM

ment is valueless temporarily to the householder whose fuse blows.

It may seem to be just a matter of routine to be able to go to your telephone at any hour, as I did, and tell the company your lights are out and have a man at your side door, as I did, to fix the trouble in a few minutes, but it is more than that.

It is an evidence of the determination of the company organization to help in the little things for which there is no charge as well as in the more important service that shows on the monthly bill.

A burned fuse may not be important to the company engineers, but they know it is important to the family in a home gone suddenly dark with company at dinner, and they have organized to take care quickly of big-little emergencies like this, just as they have prepared to meet more serious accidents that might interrupt "good public service." A SATISFIED CUSTOMER.

Here is evidence indeed that the customer has gained a fuller understanding of the Baltimore company's business, and it shows the possibilities for building good will where the utility takes the pains to put its story honestly before the public.

## Boston League Launches Electric Home

COINCIDENT with the organization of the Boston Electric League plans were approved for the establishment of an "electric home" group under the auspices of the central-station, jobbing and contracting branches of the industry in eastern Massachusetts. H. B. Gilmore was elected president of the league, Frank S. Price vice-president, Welles E. Holmes secretary, R. M. Miller assistant secretary and Rockwell C. Tenney treasurer. Fifty-three electrical men pledged their support to the league and its work. Committee chairmen elected were: Publicity, L. D. Gibbs; wiring and illumination, I. L. Matson; appliances, K. L. Norris, and house manager, W. J. Freethy.

The Boston "electric home" project is being conducted through the co-operation of prominent real-estate men and house-furnishing firms with the league, and it is planned to open the first home in Newton, Mass., April 14 and to exhibit it until May 5 on weekdays, for subscribers from 10 a.m. to noon and for the public from 2 to 10 p.m. The home is to be run on a purely educational basis, without distinctive identification or demonstration of appliances. Other homes will be established later in other places in eastern New England.

## A Decisive Victory for the Electric Truck

BACK of the accompanying advertisement offering at auction the complete delivery equipment of a baking company is a most convincing piece of evidence of the superiority of the electric truck for city delivery. As stated in the advertisement, the equipment was disposed of because the owner, the Wagner Pastry Company, Newark, N. J., was changing to electric trucks. This move is largely the result of missionary work and co-operation on the part of the electric vehicle department of the Public Service Electric Company in Newark, and R. R. Young, new-business agent of the company, in telling of the change-over says:

**AUCTION OF DELIVERY EQUIPMENT**

**DON'T FORGET ON DECEMBER 15**

WE WILL SELL FOR THE WAGNER PASTRY COMPANY, NEWARK, N. J., AT PUBLIC AUCTION, WITHOUT RESERVE, TO THE HIGHEST BIDDER, THEIR ENTIRE DELIVERY OUTFIT OF HORSES, WAGONS, HARNESSES AND GAS AUTOMBILES, ALL IN FIRST-CLASS CONDITION, ON ACCOUNT OF THEIR CHANGING TO ELECTRIC TRUCKS, ON FRIDAY, DECEMBER 15, 1922, AT 10 A. M., AT THE COMPANY'S STABLE, VESEY STREET, NEWARK, N. J., CONSISTING OF—

57 Horses
7 Mules
32 Top Wagons
1 Concord Buggy
2 Double Trucks
14 Sets Single Harness
21 Sets Double Harness
90 Collars
1 Set New Single Harness
1 Horse Swing
1 Oat Crusher
Blankets
Stable Utensils

6 1922 1-Ton Ford Trucks with Bodies.
2 1922 1-Ton Ford Truck Chassis.
4 1922 ¾-Ton G. M. C. Truck Chassis.
3 1922 ¼-Ton G. M. C. Trucks with Bodies.
7 2-Ton Pierce-Arrow Trucks with Bodies
These Cars are all in first-class mechanical condition.

**The Vogel & Schonfeld Commission Stables**

ELECTRICS DISPLACE GAS TRUCKS AND HORSE-DRAWN WAGONS

"The Wagner Pastry Company is purchasing 177 electric trucks, which, so far as we know, is the largest single order that has been placed for these vehicles. They are to supersede the gasoline trucks and horse-drawn vehicles used by the baking company on its delivery routes, which now cover a total of 3,500 miles daily.

"The Wagner Pastry Company first began to experiment with electric trucks about fifteen months ago, when it ordered six wagons from the Commercial Truck Company and several of other makes. These were tried out on all of the company's routes. To prove beyond a doubt that electric trucks would be satisfactory the tests were continued for fifteen months. The results proved that electric trucks are more satisfactory than any other type of delivery equipment.

"The trucks were used for a whole winter, careful records being kept of the various items of cost. W. J. Bittles, president of the Wagner Pastry Company, stated: 'We expect to save $100,000 a year with 70 of these trucks at our Newark plant, where they will replace an equal number of gasoline trucks and wagons.'"

Data covering the tests and performance of these trucks, with which it was decided to replace all of the gas trucks and horse-drawn wagons, will be published in a later issue of the ELECTRICAL WORLD.

## What Other Companies Are Doing

**New York City.** — Results of a census of electric signs by the New York Edison Company shows that there are 9,577 electric signs along Broadway and all other streets in the five boroughs of New York. More than a million lamps of various kinds are used in these signs. Of these lamps 947,623 are the 10-watt size.

**Fitchburg, Mass.**—The Fitchburg Gas & Electric Light Company, F. S. Clifford, sales manager, sold 400 table, bridge, floor and boudoir lamps during the year just ended and a total of 1,381 other major appliances which are estimated to add about 71,000 kw.-hr. to the system's output per year.

**Hartford, Conn.**—Appliance sales of the Hartford Electric Light Company for 1922 totaled about $155,000 against about $107,000 for the preceding year. January, 1923, sales ran about one-third ahead of the corresponding month last year. Improving industrial conditions, active merchandising effort and a rate composed of an area charge and a 6-cent energy charge have all been factors in the above results.

**Vancouver, B. C.** — To the Oak Bay district, served by the British Columbia Electric Railway Company, goes the honor of serving the first permanent entire electrical home. This place is not for demonstration purposes, but for ordinary occupation. The residence is a bungalow which, besides having an all-electric kitchen, is completely heated electrically. The connected load is approximately 25 kw.

**Springfield, Ill.**—During the five weeks ended Dec. 30, 1922, the Central Illinois Public Service Company gained 650 electric customers, sold merchandise to the amount of $49,861.01, connected to its lines 351 kw. of lighting load and 1,963 kw. of power load and contracted to serve 7,199 kw. of additional power load.

# Digest of Electrical Literature

Including Brief Abstracts of and References to Important Articles Appearing in the Scientific and Engineering Press from All Parts of the World

## Hydro-Electric Development and Steam Equipment

*Comparing Value of Power-Plant Fuels.*—G. M. LEVY.—A graphic method of computing cost of steam generated with oil or coal as fuel is described. Three charts are included for determining the cost of steam with various fuels, steam costs for varying efficiencies, heat values and coal costs, using both 2,000 lb. and 2,240 lb. as making a ton of coal.—*Power Plant Engineering*, Dec. 1, 1922.

*Modern Boiler-Feed Regulation.*—E. W. NICK.—A regulator that feeds a boiler continuously as long as it is under load, but at the same time lowers the water level during peak and overloads so as to increase the steaming capacity and during subnormal and no loads raises the water level so as to conserve the energy which would otherwise be wasted is the subject of this article.—*Sibley Journal of Engineering*, November and December, 1922.

*Furnace Maintenance with Pulverized Fuel.*—M. W. ARROWOOD.—The effect of imperfect mixing in causing overheating of brick surfaces, abrasion of eddying currents, efficient firing and maintenance are points in connection with the pulverized-fuel system that are discussed in the article.—*Iron Age*, Dec. 21, 1922.

*Combustion of Bituminous Coal.*—R. REDDIE.—The author discusses in a practical manner boiler-furnace material, the action within the furnace during combustion, elementary chemistries of combustion, etc.—*National Engineer*, December, 1922.

## Generation, Control and Switching

*Electric Generator Troubles.*—R. L. TULLIS.—Failure of the power and light generating equipment of a large institution with its own power plant sometimes calls for quick thinking and action on the part of the engineer. Some of the most common troubles that arise and methods for overcoming these are described. — *National Engineer*, January, 1923.

*Causes of Reversed Polarity in Direct-Current Generators.*—CLARENCE LYNN.—A number of conditions that may cause reversal of polarity, with methods for correction, are discussed.—*Power*, Jan. 9, 1923.

*The Applications of Relays.*—L. A. TERVEN.—The most common method of protecting alternating-current apparatus against internal faults is by means of current overload relays. This is really an application of the differential current relays, where the current entering a transformer and leaving it is made to pass through a relay which trips out the circuit when there is an unbalance within the transformer. The general application of this form of relay for various types of electrical apparatus is described.—*Electric Journal*, December, 1922.

## Transmission, Substations and Distribution

*Corrosion of the Lead Sheaths of Cables by Water Seeping Through Concrete.*—G. C. BUNKER and A. H. KHACHADOORIAN.—The cost of the repairs to the control cables at the Miraflores locks of the Panama Canal is large enough to call attention to the breakdowns and damages liable to result to unprotected cables installed in damp locations in concrete-covered duct lines and to merit a careful study of the conditions of each installation so that similar failures may be avoided. To prove that the water in the lock chambers, after dissolving lime salts from concrete, would attack lead several laboratory experiments were made, the results of which are narrated.—*Journal of the Worcester Polytechnic Institute*, November, 1922.

*Full and Semi-Automatic Versus Manual Operation for Substations.*—C. M. DAVIS.—A statement of the principles involved, showing that the interurban railway application is simpler than the urban, but that labor, feeder copper and incidental savings in general more than offset the fixed charges on the additional investment, is the most important part of this paper, presented at the annual meeting of the Central Electric Railway Association, Louisville, Jan. 18.—*Electric Railway Journal*, Jan. 27, 1923.

*A Low-Voltage Cathode-Ray Oscillograph.*—J. B. JOHNSON.—In the new type of Braun tubes low-voltage operation has been obtained by the use of a Wehnelt cathode as the source of electrons, so that the lower limit of voltage is set by the effect of the electrons on the fluorescent screen and not by the voltage needed to obtain the electrons. The tubes are designed to operate at 300 volts to 400 volts.—*Electrical Communications*, Vol. I, No. 2.

## Units, Measurements and Instruments

*Magnetic Observations by United States Coast and Geodetic Survey in 1921.*—D. L. HAZARD.—A comparison of the declination results obtained at repeat stations throughout the United States, Alaska, Hawaii, Porto Rico, the Virgin Islands and Siberia during 1921 is given. The results of earlier observations in the same localities are presented in table form. The investigations indicate that in the past few years there has been little change of declination in the southwestern part of the country and a decrease in the northwestern part.—*Serial No. 205 of the United States Coast and Geodetic Survey.*

## Illumination

*Recent Developments and Modern Requirements in Street Lighting.*—H. T. HARRISON.—In a paper presented before the British Illuminating Society the author refers to the great importance of good public lighting in promoting order and safety in the streets. The burden of rates is one reason why progress has been delayed, but improved street lighting need not always be at an increased expenditure. He also pointed out that the classification of streets on the basis of minimum horizontal illumination by joint committees on this subject in England and the classification by the street lighting committee of the N. E. L. A. were in close accord as to the amount of light. —*Electrical Times*, Dec. 28, 1922.

*Equipment to Improve the Lighting of Homes.*—P. C. KELLER.—The problem of lighting homes already occupied is radically different from that of designing proper illumination for a house in course of construction. This article presents a survey of suitable equipment with suggestions for simple demonstrations to show the advantage of good practice as compared with bad, and it pictures equipment suitable for carrying on this work.—*N. E. L. A. Bulletin*, January, 1923.

## Motors and Control

*Applying the Electric Motor to the Pulp Industry.*—GORDON FOX.—The heavy machinery used in the manufacture of pulp for paper making is well adapted for motor drives. A detailed description of these drives is given.—*Power Plant Engineering*, Dec. 1, 1922.

*Determining the Performance of an Induction Motor Without Plotting a Circle Diagram.*—G. T. SMITH.—A method is described for determining induction-motor characteristics that is easier than the circle diagram and has the added advantage that the accuracy of the result is not dependent upon reading values from charts. The method is in fact the circle diagram put into mathematical terms.—*Electric Journal*, December, 1922.

*Operation of Direct-Current Motors.*—E. C. PARHAM.—Features of application and operation, characteristics of different types and troubles encountered and their remedies are the chief points considered.—*National Engineer*, January, 1923.

*Production of Noise and Vibration by Squirrel-Cage Induction Motors.*—F. T. CHAPMAN.—A suggestion is made that the high-pitched notes emitted by some induction motors are due to a side pull arising from an unsymmetrical field which may be produced when cer-

tain numbers of rotor slots are used. A simple case is first considered and the dissymmetry shown, the forces produced being indicated and their effects considered. The motor field is analyzed, and it was found to include pairs of components such that in each pair the numbers of poles differ by two. *Institution of (British) Electrical Engineers*, December, 1922.

## Heat Applications and Material Handling

*Coal Handling and Electricity Supply.*—G. F. ZIMMER.—When coal is received by both railway and waterway the difficulty of handling is much greater than if coal is received at one source only. At the Blackburn (England) power station a novel traveling crane is employed that can either take coal from a barge or pick up railway cars bodily and empty them into the storage yard.—*Electrician*, Dec. 29, 1922.

*Electric Welding of Storage Tanks.*—Report of the American Welding Society committee, working with the American Bureau of Welding, on the specifications for the welding of a 5,000-barrel tank by the electric process. Specifications are included in the report.—*Journal of the American Welding Society*, December, 1922.

*Ferro-Alloys and Hydro-Electric Power.*—F. A. J. FITZGERALD.—The author contrasts the popular clamor for the benefits of cheap electricity from water power with the propaganda designed to discourage the reasonable use of such natural resources as Niagara Falls. Demand for ferro-alloys is increasing, and the question is raised as to where the great quantities of cheap electric power which are needed for the natural growth of the ferro-alloy industry are to come from. —*Iron Age*, Jan. 4, 1923.

## Electrophysics, Electrochemistry and Batteries

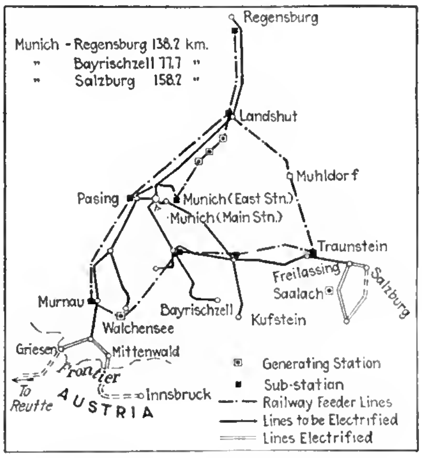
*Five-Wire Balancers for Charging the Batteries of Electric Vehicles.*—J. P. KEMP.—The advantages of the five-wire system for charging electric storage batteries are outlined. A table shows the cost of such a system as compared with the cost of an ordinary motor-generator set operating directly from 440-volt mains, and a detailed description is given of the five-wire system. The method of employing the balancer set is explained.—*Electric Vehicle*, November and December, 1922.

*Atomic Systems Based on Free Electrons, Positive and Negative, and Their Stability.* — R. HARGREAVES. — In the atomic scheme, of which a planetary system is the model, negative electrons have the position of planets and a positive charge is condensed at a central nucleus. It is then postulated from experience — chemical, electrical and spectroscopic—that the nucleus shall contain an integral number of standard charges. The question of how far these structures, regarded as representations of the atom, meet the demands from the various branches of physics and chemistry is a fundamental one to which the author devotes forty pages.—*Philosophical Magazine*, December, 1922.

*Vapor Recompression Systems for Evaporators.*—W. L. BADGER.—A technical history of regenerative evaporation, enumerating the advantages and shortcomings of this system, is given. This is followed by an analysis of recorded data on test runs, a critical discussion of the regenerative evaporating system with particular reference to the general theory of design and construction, comparison of operating economies with single and multiple-effect evaporators and a bibliography of patents and literature references.—*Chemical and Metallurgical Engineering*, Jan. 3 and 10, 1923.

## Traction

*Electric Traction in Bavaria.*—B. GLEICHMANN. — The electrified lines and proposed lines in Bavaria are shown in the accompanying illustration. Electric operations began in 1912 on the Mittenwald Railway, power being supplied at 50,000 volts from the Reutz works. The system adopted was single-phase at $16\frac{2}{3}$ cycles, with overhead-conductor pressure of 15,000 volts



ELECTRIFIED RAILWAYS IN BAVARIA

in conformity with the system used in other German states which have adopted electrification. The extensions since that time, working costs, sources of supply and details of system employed, as well as the advantages of the single-phase system used, are among the factors discussed.—*Electrician*, Jan. 5, 1923.

*Electric Locomotives for Norfolk & Western Railway.*—Four double-unit 4,000-hp. locomotives are under construction for the Norfolk & Western Railway's Elkhorn grade and electrified extension. These will supplement twelve lighter locomotives that have been in service since 1915. A general description is given of these locomotives, including the equipment that they will carry.—*Electric Railway Journal*, Dec. 30, 1922.

## Telegraphy, Telephony, Radio and Signals

*Characteristics of 5-Kw. Elwell-Poulsen Arc Generator.*—A. T. C. MOORE.—Tests were made on this type of generator to determine the distribution of transverse magnetic field in the air gap, the effect of magnetic field on the magnitude of the high-frequency current, and the relation of wave lengths to the high-frequency current, the generator operating with the field coils connected in series with the arc.—*Engineering*, Dec. 8, 1922.

*An Electron Tube Amplifier.*—P. D. LOWELL.—The apparatus described is an amplifier developed by the Bureau of Standards using a crystal detector and five stages of amplification, three stages of radio-frequency amplification and two stages of audio-frequency amplification. The tubes are energized from a 60-cycle supply for both filaments and plates. Circuit diagrams and values of condensers, resistors and inductors used are included.—*Scientific Paper No. 450 of the Bureau of Standards.*

*Calculation of an Antenna.*—F. PERRIN.—The author shows the way in which a somewhat unusual antenna was calculated for its mechanical strength and its electrical characteristics. The efficiencies of this antenna are then investigated mathematically for five different wave lengths.—*Revue Générale de l'Electricité*, Dec. 23, 1922.

## Miscellaneous

*Reclamation of Used Petroleum Lubricating Oils.*—W. H. HERSCHEL and A. H. ANDERSON.—Used lubricating oils may be reclaimed by apparatus already commercially available and thus saved for further use. Such reclaimed oils will pass all the commonly accepted tests for new oils, such as flash point, viscosity and sediment. It is often the case that high acidity is accompanied by readiness of emulsification, but exceptions have been found, so that the value of the test for acidity must lie in the possibility that an oil of high acidity will not prove durable in use. Important points discussed are the deterioration of lubricating oils in use, present methods of reclaiming used oils, tests with motor-oil purifier refining processes and the cause of sludge formation.—*Technologic Paper No. 223 of the Bureau of Standards.*

*Neon-Glow-Discharge Lamp on Alternating-Current Circuits.* — R. A. BROCKBANK and L. E. RYALL.—After giving the various characteristics of this type of lamp by means of numerous curves, the author suggests further experiments that should be carried on to determine future applications. Among these experiments would be a detailed study of the lamp for stroboscopic purposes at all frequencies, a study of the photometric properties of the lamp and experiments to determine the possibilities of its use for photographic purposes. — *Electrician*, Jan. 5, 1923.

# New Books

Reviews of the Latest Contributions to
Technical, Industrial and Commercial Literature of Particular Interest
to Members of the Electrical Industry

### Theoretical and Practical Electrical Engineering

By Louis Denton Bliss. Vols. I and II. Washington, D. C.: Bliss Electrical School. 1470 pages.

This treatise includes a very complete discussion of the fundamentals and application of electrical phenomena. The descriptions are, in general, clear without the use of mathematics. A much larger range of electrical applications is included than in the usual textbook. A large number of illustrations are used to illustrate fundamental principles and wiring connections. Complete machines are illustrated as well as their constructional features. Historical facts are introduced in a manner to add interest.

There may be exceptions taken to a few explanations of certain features of electrical apparatus. In the treatment of generators the fact that field distortion is corrected by commutating poles is emphasized. This, of course, is not true except at the point of commutation. In a later discussion on commutating-pole motors this point is clarified. In describing three-wire generators with balance coils an incorrect statement is made, that the current in the outside wires is continuous while the current in the middle wire pulsates between points of maximum and zero value. Obviously any pulsation in current must be the same throughout the circuit and will be small as it is due to the varying resistance in the armature circuit and leakage reactance of the balance coil. The treatment of the transformer is very good in detail and introduces a more accurate conception of leakage flux than can be gained from many textbooks.

The subjects covered include static electricity, electric circuit, magnetic circuit, electromagnetic phenomena, wiring for bells, lighting, etc., measuring instruments and use of same, direct-current generators, boosters and motors, alternating-current principles (with the minimum of mathematics), alternators, transformers, synchronous motors, induction motors, synchronous converters with their modern developments, phase advancers, single-phase induction motors, and commutating motors both single-phase and polyphase.

Applications of electrical apparatus are also described, with the modifications for the particular application, including electric elevators, automobile engine ignition, starting and lighting, electric railways, communication and illumination. The power system is treated by a brief description of prime movers as well as an account of power transmission by various systems and power station protective and metering devices.

From the standpoint of instruction the questions at the end of each chapter serve to emphasize the important facts of the chapter. However, a larger number of numerical problems might be used to clinch certain facts.

The completeness and simple treatment of electrical phenomena should give these two volumes a definite place among electrical engineering literature, particularly for the man who has not been able to keep up with the development of modern apparatus or who has not been fortunate enough to have a college education. R. G. WARNER.

### André Marie Ampère, 1775-1836

A special issue of the *Revue Générale de l'Electricité*, dated November, 1922, is dedicated to the memory of Ampère. This elaborate publication of more than 300 pages contains nine chapters of a biographical nature dealing with the life and achievements of the great French electrophysicist. Then follows a description of the recent centennial Ampère festival in France, all the addresses being published. The second half of the book gives descriptions of the salient features of forty of the most important electrical generating centers of France. The first part of the book will be of great value to the historian and bibliographer, and the second part will serve as an excellent and up-to-date reference book on the existing electric systems of France.

### Principles of Electric Spark Ignition in Internal-Combustion Engines

By J. D. Morgan. London: Crosby, Lockwood & Sons. New York: D. Van Nostrand Company. 92 pages with diagrams.

This is not a book describing the construction and operation of electrical ignition apparatus, which fact makes it unique in the literature of electrical ignition. It presents the physical facts underlying gas ignition. The treatment is purely physical and descriptive, with an almost complete absence of mathematics.

The discussion covers such matters as gas characteristics (inflammability, rate and manner of flame propagation), spark characteristics (capacity and inductance components of spark currents), effects of sparks on gases, effect of spark-gap form on sparks and ignition, effects of inductance and capacity of spark generator and spark circuit, and effect of resistance leak across spark gap. The subject matter is in part a collection of information scattered through technical journals, but more largely the result of the author's own investigations. The presentation is pleasantly clear and comprehensible. Intended primarily for the designer of gas engines or ignition equipment, the book is of interest and value to any engineer who drives a car and is interested in its operation. W. B. HALL.

### The Lead Storage Battery

By H. G. Brown, A.M.I.E.E. London: The Locomotive Publishing Company. 162 pages, 60 illustrations.

The fundamental theory of the lead storage battery is very well set forth in this book and in terms that will be found quite clear to a reader not thoroughly posted in electrochemical theories.

In taking up the description of different types of plate and cell assemblies and various storage-battery applications, including details of installation and auxiliary apparatus, however, the book is practically limited to English practice. In many respects European practice is so different from that in this country that the descriptive matter is of little value and may in some cases be actually misleading to one who is looking for information in regard to storage-battery practice in the United States. For example, the discharge curves given in Fig. 7 on page 17 show final voltages which are considerably higher throughout the entire range of discharge rates than those which have been established as standard in this country. As another example, on page 27 the statement is made that the Planté positive is without a serious rival for stationary battery work. In this country the Faure, or pasted plate, has been almost universally adopted for standby service for the large standby batteries in central-station lighting systems.

In many places the descriptive matter reveals a prejudice on the part of the author in favor of the product of a particular manufacturing company, which is rather unfortunate in a book supposed to deal with the subject generally and from an unbiased standpoint

Some of the fundamental data do not appear to be quite correct, such as the curve given in Fig. 3, page 11, showing the variation of open-circuit voltage with acid density. The temperature at which this curve is intended to be used is not given, but if a temperature of 80 deg. F. be assumed, which will make the highest point on the curve correct, the rest of the curve is too high.

## Books Received

**Practical Tests for the Electrical Laboratory.** By Chesley H. Johnson and Ralph P. Earle. New York: D. Van Nostrand Company. 347 pages, illustrated.

**Engineering Economics.** By John Charles Lounsbury Fish. New York: McGraw-Hill Book Company. 311 pages.

**Rate Making for Public Utilities.** By Lamar Lyndon. New York: McGraw-Hill Book Company. 209 pages.

**Lehrbuch der Praktischen Physik.** By Friedrich Kohlrausch. Leipzig: B. G. Teubner. 802 pages, illustrated.

# News of the Industry

**Chronicle of Important Events and General Activities, Announcements and Reports of Association Meetings, Court Decisions and Commission Rulings and News of Electrical Men**

## Reorganization of Northern Illinois Company

The Public Service Company of Northern Illinois on Feb. 6 announced the executive reorganization of the company to meet exigencies created by the death of Frank J. Baker, vice-president of the company. Samuel Insull resigned from the presidency to become chairman of the board with general authority over the company's affairs conferred by amendments to the bylaws. Britton I. Budd, president of the Chicago Elevated Railroads and the Chicago, North Shore & Milwaukee Railroad, was elected president; John G. Learned was elected vice-president in charge of the commercial and new-business departments, and Julius L. Hecht was made vice-president in charge of engineering and operation. Charles A. Munroe resigned as vice-president, but retains his position as a director and a member of the executive committee. John H. Gulick remains vice-president in charge of finances.

## Carrier Current in Operation at Hartford

One of the "wired-wireless" installations now being made by central-station companies as an aid to operation has, with characteristic enterprise, been put into use by the Hartford (Conn.) Electric Light Company between its South Meadow and Falls Village generating stations. This installation differs from others in that it is the first one to be made on a long rambling transmission line with numerous taps. A frequency of 13,000 cycles is used, and the sound wave is impressed on the 66,000-volt transmission line through a coupling wire which is about 1,000 ft. long and runs parallel to and within a few feet of the high-tension wires.

The transmitter contains two 50-watt tubes. When the microphone is spoken into, the voltage on the grid of the second tube, called the modulator, is varied. This in turn creates a much greater variation in the current flowing from the plate of this tube to the filament. Since the plates of the modulator and oscillator tubes are connected in parallel, the current in the plate of the oscillator will vary, and this causes a variation in the amplitude of the oscillations generated; in other words, the voice frequency is carried along with the carrier frequency. The receiving unit contains three tubes, a detector and two amplifiers. Different combinations of tubes may be used for receiving the calling and taking frequencies. The receiving tubes burn constantly and a switch is so connected that while one battery is lighting the filaments another one is being charged.

## News from the Capital

**Ford Bill Doomed — Radio Bill Meets Obstacle—Ratification of Colorado Treaty in Doubt**

ALTHOUGH the announcement by Representative Madden, the chairman of the appropriations committee of the House, that he regards it as desirable for Congress to accept Henry Ford's Muscle Shoals proposition did much to stimulate the flagging hope of the advocates of that proposal, the Washington correspondent of the ELECTRICAL WORLD reports that it apparently has brought the realization of those hopes no nearer. It is admitted that support from such a prominent member of the House of Representatives is a great asset to the advocates of the Ford offer, but it is an asset which will be of little service in this Congress, since it is conceded that no vote can be had in the Senate at this session. The bill, therefore, will die with the Congress on March 4.

The radio bill is in a very difficult position in the Senate. Its passage virtually depends on its receiving unanimous consent. This seems improbable owing to the fact that a number of Senators are insisting that action wait on an international agreement. Secretary Hoover, however, has taken pains to call attention to the fact that a recent federal court decision does away with every shred of authority which his department has been exercising over radio matters.

Doubt as to the ratification of the Colorado River compact by Congress at this session has been expressed by Secretary Hoover. Delay on the part of Arizona and Colorado in securing its ratification by their legislatures has precluded consideration of the compact by Congress so long that, in the face of the usual congestion of legislation at the close of the session, federal action, even if those states should take belated action, is endangered. Mr. Hoover emphasizes the responsibility which those states are assuming in delaying works of flood protection and those necessary to the utilization of the resources of the river. He points out, however, that failure on the part of the legislatures of Arizona and Colorado as now constituted in no way impairs the existence of the compact itself, which can be ratified at any future time.

## Edison Seventy-six Years Old Tomorrow

Tomorrow, Feb. 11, Thomas A. Edison will be seventy-six years old. There will be no celebration on Sunday, but on Monday the Edison Pioneers, composed of Mr. Edison's associates between 1885 and 1900 and the descendants of his associates before 1885, will hold their annual meeting and luncheon in the Edison plant at West Orange, N. J. Mr. Edison's presence at this luncheon is always an event of great interest to his old associates.

No special program has been arranged. Samuel Insull, president of the Edison Pioneers, will speak. John W. Lieb is chairman of the dinner committee, other members of which are C. E. Esterbrook of the General Electric Company, F. A. Scheffler of the Fuller Engineering Company of New York, vice-president of the Pioneers; William H. Meadowcroft, confidential secretary and personal representative of Mr. Edison, and Frank A. Wardlaw, curator of the Museum of Edisonia and secretary of the Pioneers.

## Radio Monopoly Debated in Congress

Just previous to the passage of the administration's bill for the control of radio, reported in last week's issue, a lively debate arose in the House of Representatives over the clause authorizing the Secretary of Commerce to refuse or revoke licenses in cases where a monopoly of radio transmission was threatened. Representative Jones of Texas led in an attempt to have the Secretary "directed" instead of "authorized" to revoke or refuse licenses in such cases and also to give to any one whose application had been refused or permit revoked or suspended the right to appeal to the courts, the Secretary's order to remain in force pending judicial decision. Mr. Jones declared that there was grave danger of a monopoly in the radio business by four great companies.

As named by Representative Jones in speaking to his amendment, these are the American Telephone & Telegraph Company and the allied Western Electric Company, the Westinghouse Electric & Manufacturing Company and the American Radio Corporation. In pursuing his remarks, however, he brought in also the General Electric Company.

The proposed amendments were defeated and the refusal or revocation of licenses because of monopoly was left to the decision of the Secretary.

## Miller's Quarter Century

**President Southern California Edison Receives Congratulations on His Twenty-five Years' Service**

A BANQUET long to be remembered by those in attendance was given at Los Angeles last week to John B. Miller, president of the Southern California Edison Company, in celebration of the completion of his twenty-fifth year of service with that company. The event, which was participated in by three hundred executives, engineers and district managers of the company, served to drive home again the ideal of service that has made possible the building of this company's great network. G. C. Ward, vice-president in charge of operation and construction, speaking at the banquet, delcared that this ideal was what had made possible the budget of new expenditures for 1923 of $26,000,000 and the coming drive for an additional connected load in the present year of 100,000 hp. or more.

Vice-president S. M. Kennedy read a score of congratulatory letters and telegrams from leaders of the electrical industry, among them Thomas A. Edison, C. A. Coffin, Frank W. Smith, Joseph B. McCall, Charles L. Edgar, Samuel Insull, W. E. Creed, John A. Britton, H. M. Byllesby and James H. McGraw.

Roy V. Reppy, chief counsel of the company, said Mr. Miller had "built not only physical transmission lines, but a human co-operative association that with its high ideals, its loyalty and its enthusiasms has shown to the people that a corporation is indeed possessed of a soul." Vice-president W. A. Brackenridge presented the twenty-five-year service button to Mr. Miller, saying that it was a symbol of the untiring effort he had displayed in behalf of the public.

### TRANS-ROCKY MOUNTAIN PROBLEMS

Mr. Miller in his response told his hearers that west of the Rockies lay 70 per cent of the undeveloped water powers with only 8 per cent of the industry of the nation. He said his vision had been to transport the industrial scenes of the East, where 42,000,000 hp. developed by steam is now used, to the West coast, where lie such vast untouched water powers.

Referring to the subject of the Colorado River and its development, alluded to in the congratulatory telegram of James H. McGraw, Mr. Miller said: "I am glad that the subject of the Colorado has been alluded to this evening. We do not as yet need the Colorado, but we stand ready to go into the Colorado if permitted to do so and carry out this great work. We are now doing work of equal magnitude, and should we undertake this development we should like to proceed in the same way we have proceeded in the past. We should like to have as partners all the people of the Colorado River Basin. We believe that such a system of development works the highest justice in economic service to the consuming public, to the employees and to the investor."

R. H. Ballard, vice-president and general manager of the company, presented to Mr. Miller a painting of a California hillside, a gift to the president from the eight thousand employees of the company.

## Ten-Year Program Beginning in Southern California

The first step in the ten-year construction program of the Southern California Edison Company, the final cost of which is estimated at $375,000,000, will be the erection of a substation in the Vernon district of Los Angeles to serve as a distributing center for power brought from the Big Creek developments. The substation, to be known as the Laguna-Bell terminal station, will have a rating of 160,000 hp., will be of the outdoor type and will cost approximately $2,000,000. Work will begin in the near future. The structure will be of the most modern type and will receive power over a new extension of the Big Creek transmission line. The connection will be made by a trunk line, 30 miles in length, which will join the main trunk line at Eagle Rock.

According to George C. Ward, vice-president in charge of construction, the entire construction project, when completed, will develop in the neighborhood of 1,250,000 hp. The power will be distributed to most of the counties in southern California.

## Solid Building Justified

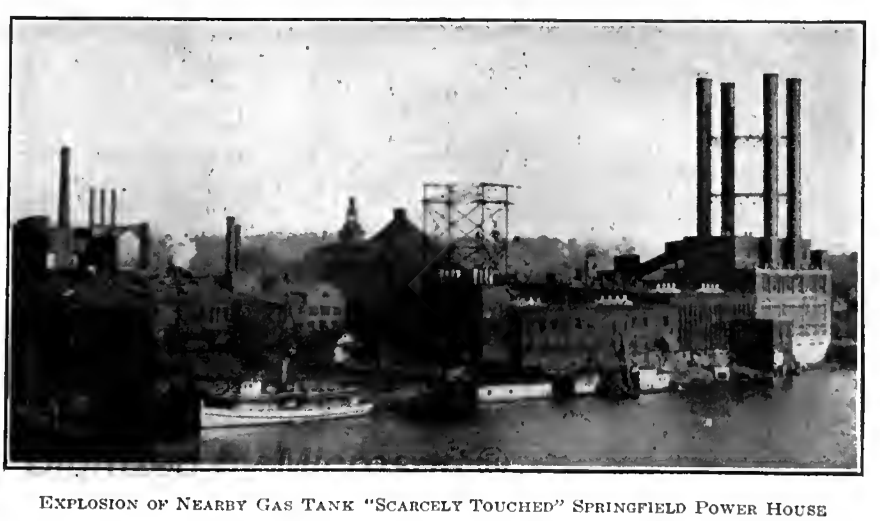
**Springfield (Mass.) Central Station Unscathed When Adjacent Gas Tank Explodes**

ELECTRIC service at Springfield, Mass., sustained no interruption and the property of the United Electric Light Company, the Springfield Street Railway, the Turners Falls Power & Electric Company and the New England Telephone & Telegraph Company escaped serious damage when a purifying tank at the works of the Springfield Gas Light Company exploded in the early afternoon of Feb. 1, although three persons were killed in the disaster, about a hundred injured and downtown property suffered an estimated loss of $500,000. The main steam plant of the United company is on the east bank of the Connecticut River within about 75 ft. of the gas plant, a recently completed boiler house and switch house facing the main line of the New York, New Haven & Hartford Railroad which divides the two properties. About 55,000 kva. in generating equipment is in service and the boiler plant is surmounted by four steel stacks 197 ft. high, supported on the framing of the building. In the switch house are the operating headquarters of the United system, and a 66,000-volt interconnection with the Turners Falls system spans the river at this point, terminating on a steel structure at the top of a transformer house at the north end of the station.

The explosion destroyed 90 per cent of the windows of an older portion of the station and several in the newer section, bulged out a portion of the old boiler-house wall no longer used; showered the office of the chief engineer with glass and covered a rotary converter with fragments. Windows were destroyed at the main office of the company 600 ft. up the street.

### SERVICE UNINTERRUPTED BY EXPLOSION

The solid construction of the boiler house and switch house completely safeguarded the employees on duty, and the service was not interrupted by the opening of a single circuit breaker. Many of the principal lines of the underground service pass the gas company's plant. The mechanical shock of the explosion caused a slight movement of recording-instrument needles in the switch house. The turbo-generators in operation showed no sign of bearing temperature rise when observed closely for eight minutes after the disaster. McClintock & Craig, Springfield, designers of the boiler house, made an immediate inspection of the plant after the explosion and reported no structural damage to either building or stacks. The switch house was designed by Stone & Webster, Boston, and went through the test equally well.



EXPLOSION OF NEARBY GAS TANK "SCARCELY TOUCHED" SPRINGFIELD POWER HOUSE

## Commonwealth Edison Plan

### Samuel Insull Tells of Power House Soon to Be Erected on the Drainage Canal

TRUE selling engineering plus true distribution engineering was declared by Samuel Insull, in the course of an address made at Chicago before the Western Society of Engineers on Thursday evening of last week, to be the basic reason for the growth of the Commonwealth Edison Company. Mr. Insull's address dealt with central-station development in Chicago from 1892 to 1922 and thereafter. After giving a historical account of the building and growth of the company's earlier stations, he came to the Calumet plant, started in 1920, which by the end of 1923 will have a rating of 200,000 kw. The growth in demand has been so great, however, that the company is now compelled to build on an even larger basis. The new plant to be erected at Crawford Avenue on the Drainage Canal will develop at least 400,000 kw., although the possibilities are that the final capacity will be 600,000 kw. The first two units will have a rating between 90,000 kw. and 95,000 kw., operating at a steam pressure of about 600 lb. The first unit is to be purchased from Charles Parsons of England, while the second will be a Westinghouse unit.

#### EFFICIENCY OF CALUMET PLANT

Referring to the increased efficiency and fuel economy obtained in the Calumet plant, which operates on 1.8 lb. per kilowatt-hour as compared with the old Adams Street plant, which required 12 lb. of coal for one kilowatt-hour, Mr. Insull declared that if economy had not been improved in the last thirty years, the annual consumption of the Commonwealth Edison Company would now be 15,000,000 tons to 18,000,000 tons of coal instead of the present consumption of 2,225,000 tons to 2,500,000 tons. This improvement has not been due merely to the increase in steam pressure but has been assisted by the use of condensers. With 400 tons to 450 tons of water pumped through the condensers for every ton of coal burned in the furnaces, the Commonwealth Edison Company pumps more water than the city of Chicago uses for all other purposes.

Estimates on the construction of a transmission system from Waukegan down to the Indiana line involve two 132,000-volt transmission lines with a capacity of 75,000 kw. each, Mr. Insull informed his hearers. Although this transmission line would cost approximately $7,500,000, it would safeguard continuity of service and save a station investment of from $10,000,000 to $12,000,000.

Mr. Insull felt that the fundamental reason for the success of the company was selling large volumes of energy. By distributing 50 per cent more energy and receiving for it one-fifth less money the company was able to make more profit on the dollar invested, he contended, than has been the case with any other large electric light and power company elsewhere in the world.

In closing the speaker paid a tribute to Frederick Sargent, who, he said, had, as a designing engineer, contributed more than any other man toward the development of central stations.

## Empire State Meter Section Meets at Syracuse

The recent annual meeting of the electric meter section of the Empire State Gas and Electric Association, held at Syracuse, brought out papers on demand-meter maintenance, by E. A. Le Fever, Buffalo General Electric Company; demand rates, by W. M. Carpenter; changing distribution from two-phase to three-phase, four-wire, by W. S. Davis, Public Service Corporation of New Jersey; effect of phase angle and power factor on polyphase meters, by J. B. Gibbs, Westinghouse Electric & Manufacturing Company; potentiometers, by I. Melville Stein, Leeds & Northrup Company; meter maintenance, by C. L. Casler, Syracuse Lighting Company; measurement of energy, by F. C. Holtz, Sangamo Electric Manufacturing Company, and jewels and pivots, by B. W. St. Clair, General Electric Company.

Mr. Le Fever said that in some cases 50 per cent of the revenue of electric companies is based on the demand element in rates. He emphasized the importance of the proper location of demand meters and of the regular and thorough cleaning of meter clocks. Mr. Carpenter said that, even ignoring the element of power factor, it is possible to obtain only an approximation of true electrical demand with the instruments now used. Mr. Davis outlined ways and means for changing over distribution, using meters already in stock and with a minimum of expense for the purchase of new transformers.

Mr. Le Fever was elected chairman of the section for the ensuing year.

## All Ready for Institute's Midwinter Convention

All preparations for the midwinter convention of the American Institute of Electrical Engineers, to be held in the Engineering Societies Building, New York, from Wednesday to Friday of next week, are complete. The only change from the program as printed in the ELECTRICAL WORLD for Jan. 20, page 180, is that there will be parallel technical sessions on Thursday morning, three of the papers scheduled for the afternoon being transferred to the morning session. At noon on Thursday the delegates will visit the building of the McGraw-Hill Company as the guests of the publishing firm.

# A Million Kilovolt-Amperes in Big Units

### Large Turbo-Generators Under Order with Westinghouse and General Electric Reach This Rating—Smaller Units and Those to Be Built by Other Firms Will Double Total

THE healthy state of the electrical industry cannot be shown more vividly than by the news that two manufacturing companies alone have under contract 1,139,500 kva. in turbo-generator units of 25,000 kva. rating and larger. Add to these units the production under way by other companies as well as the smaller units being built by the two companies referred to and an estimate of about two million kilovolt-amperes is obtained, representing the power equipment now being made under order from central-station companies.

In order to show the type of unit and the nation-wide extent of the buying, the tabulation given below should be interesting.

The Detroit Edison turbines are for a new station at Trenton Channel; the American Gas & Electric equipment is for a new station at Philo, Ohio; the General Electric turbines for Cleveland, Philadelphia and Chicago will be added to existing stations, as will the equipment ordered by the New York Edison Company. The turbines the Westinghouse company is building for the Commonwealth Edison are for its Calumet station and the coming station on Crawford Avenue, the Brooklyn equipment will go in its new Hudson Street station and the Public Service Production Company's generator will be installed at Jersey City.

LARGE TURBO-GENERATOR UNITS NOW CONTRACTED FOR

| Company Ordering | No. of Units | Rating, Each, Kva. |
|---|---|---|
| **General Electric Company** | | |
| Detroit Edison | Three | 50,000 |
| American Gas & Electric | Four | 35,000 |
| Cleveland Electric Illuminating | One | 30,000 |
| Public Service of Northern Illinois | One | 30,000 |
| Minneapolis General Electric | One | 30,000 |
| Commonwealth Edison | One | 30,000 |
| Philadelphia Electric | Two | 30,000 |
| New York Edison | One | 35,000 |
| New York Edison | One* | 35,000 |
| **Westinghouse Electric & Manufacturing Company** | | |
| Commonwealth Edison | One | 50,000 |
| Commonwealth Edison | One | 37,000 |
| Brooklyn Edison | One | 62,500 |
| Connecticut Light & Power | Three | 25,000 |
| Middle West Utilities | Two | 25,000 |
| Indiana Public Service | Two | 25,000 |
| Counties Gas & Electric† | One | 25,000 |
| Denver Gas & Electric | One | 25,000 |
| Moline & Rock Island Manufacturing Co. | One | 25,000 |
| West Penn Power | Two | 30,000 |
| Public Service Production (N. J.) | One | 25,000 |
| Luzerne County (Pa.) Gas & Electric | One | 25,000 |
| Lorain County (Ohio) Gas & Electric | One | 25,000 |
| Toledo Edison | One | 37,500 |
| Metropolitan Edison‡ | One | 37,500 |
| Pennsylvania Railroad‖ | One | 25,000 |

# From Mexico to Puget Sound

### Closing of Two Gaps, Which Is Now Under Way, Will Provide an 1,800-Mile Interconnected Power System on the Pacific Coast, with a Generating Capacity of 1,640,000 Kw.

COULD a kilowatt be isolated at Yuma, Ariz., equipped for travel with a through ticket and a clear line, it would be possible to transfer it to Albany, Ore., over approximately 1,200 miles of copper, composing the backbone of a superpower system whose annual kilowatt-hour output is almost one-tenth the total annual consumption of electrical energy in the United States and whose network of transmission and distribution lines exceeds half the total railway mileage of America. While the East has been talking and agitating for a superpower system in the Boston-Washington district, Western public service companies have gone quietly about the business of interlinking their lines until at the present time there has been built up an interconnected network which covers three states and which within the next eighteen months will cover the entire Pacific Coast, from the Mexican border to Puget Sound.

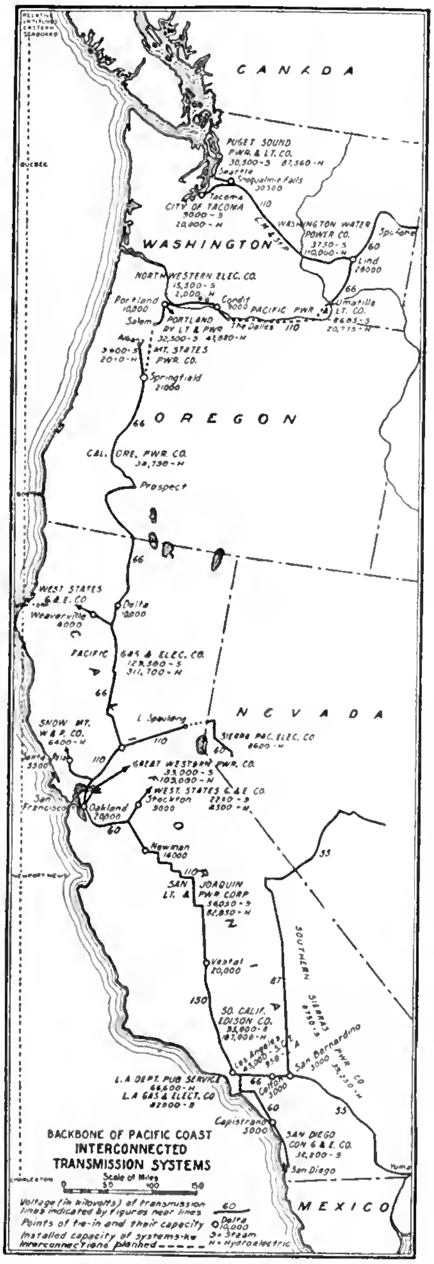
THE REMAINING GAPS

The Pacific Coast Interconnected Transmission System at the present time comprises all of the major California power companies and two of the important Oregon utilities. Plans are now under way for the closing of the two remaining gaps in the Pacific Northwest, and when this is done there will then exist a superpower system whose main trunk will be approximately 1,800 miles long, whose generating capacity, both steam and hydro-electric, will be nearly 1,700,000 kw., and whose annual output will be close to 6,000,000,000 kw.-hr. Were this system to be transposed to the Atlantic seaboard, it would serve a territory extending from Quebec, Canada, to Charleston, N. C.

The lines of the system cross barren deserts, traverse fertile valleys and wooded hills, and finally climb through a pass in the Sierras to carry power to the Nevada mines. They are fed by steam plants fired with oil and natural gas and by hydro-electric plants whose generators are turned by waters from the eternal Sierra snowbanks or from the never-diminishing springs of the Pit River. Even the vagaries of nature are overcome, for in years when rainfall is light in the south and water scarce power can be sent from the north to make up the resulting shortage.

Some idea of the immensity of the present interconnected system existing on the Pacific Coast can be gained from the figures it involves. The present system includes the lines of eleven major companies and one municipality, involving a total steam generating capacity of 402,150 kw. and a hydro-electric generating capacity of 839,990 kw. The annual output of the system for the year ended Dec. 1, 1922, was 4,330,640,821 kw.-hr.

The two gaps which must be closed before the lines of the Pacific North-



BACKBONE OF PACIFIC COAST INTERCONNECTED TRANSMISSION SYSTEMS

west will be tied in with those of California are shown in the map. There is a transmission line at the present time between Springfield, Ore., and Portland, which is the property of the Oregon Electric Company and which operates at 33 cycles. The lines of the Mountain States Power Company and the California Oregon Power Company, which are joined at Springfield, both operate on 60 cycles. The Oregon Electric Railway Company is at the present time installing twelve automatic substations which will operate on 60 cycles, and upon the completion of this installation it is planned to change over the lines to 60 cycles and interconnect with the California Oregon Power Company at Springfield. The Portland Railway, Light & Power Company supplies the railway transmission line, and when this connection is made the interconnected system will extend to The Dalles, Ore., over the system of the Pacific Power & Light Company, which is tied in with that of the Portland Railway, Light & Power Company.

The second gap exists between two of the divisions of the Pacific Power & Light Company. Surveys are being made for a line along the banks of the Columbia between The Dalles and Umatilla and officials of the company predict that the line will be completed within the next eighteen months. When these two gaps are closed there will be added to the interconnected system 99,815 kw. in steam generating capacity and 298,215 kw. in hydro-electric generating capacity.

Interconnection, then, as far as the Pacific Coast is concerned, is an accomplished fact. Quietly, without the blare of trumpets, there is being built up a superpower system which eclipses anything in the world—a system which will serve four states and a population of approximately 5,600,000.

## Tidewater Power Company to Expand

The Tidewater Power Company of Wilmington, N. C., controlled by A. E. Fitkin & Company of New York, is to proceed at once with the construction of a transmission line from Wilmington to Warsaw and Clinton. The line will be about 68 miles in length and cost approximately $130,000. Cotton mills and other manufacturing plants will be served, and it is expected that a number of towns between Wilmington and the two places named will also be supplied with light and power.

## A. M. E. S. Schedules Its March Meetings

The following schedule of section meetings has been drawn up by the Associated Manufacturers of Electrical Supplies for the week beginning March 5. All meetings will be held in the association offices, 30 East Forty-second Street, New York.

MONDAY, MARCH 5

1:30 p.m.: General standards committee. 7:45 p.m.: Committee on section activities.

TUESDAY, MARCH 6

10 a.m.: Snap switch section, molded or formed insulation section, laminated phenolic condensation products section. 2 p.m.: Line material section, lamp receptacle and socket section, air circuit-breaker section. 4 p.m.: Attachment plug section.

WEDNESDAY, MARCH 7

10 a.m.: Fuse section, fan motor section, carbon section, rigid conduit section. 11:30 a.m.: Non-metallic conduit section. 2 p.m.: Armored conductor and metallic flexible conductor section; knife switch section, industrial lighting section. 4 p.m.: Metal molding section.

THURSDAY, MARCH 8

10 a.m.: Panelboard and switchboard section, outlet box section, signaling apparatus section.

FRIDAY, MARCH 9

10 a.m.: Heating appliance section. 2 p.m.: Meeting of board of governors.

## Federal Power Commission Activities

The Tennessee Hydro-Electric Company of Knoxville has applied to the Federal Power Commission for a preliminary permit for projects on the Clinch and Powell Rivers in Tennessee and Virginia. These streams are tributaries of the Tennessee. The ultimate installation of 390,000 hp. is contemplated. The company draws its financial support from New York and Pittsburgh interests. J. R. Paul of Pittsburgh is president. The same interests previously applied for a preliminary permit covering three projects on the Holston River.

The Virginia Power Company, a going concern in West Virginia, has applied for a preliminary permit for a large development on New River, 5 miles above Hinton. The power will be used to extend the present system of the company, which is furnishing power to coal mines, public utilities and manufacturing plants in that region.

The Louisville Gas & Electric Company has declared its intention to apply to the commission for a preliminary permit covering projects on the Green and Cumberland Rivers in Kentucky.

The Susquehanna Power Company of New York recently filed a declaration of intention covering the construction of a dam 70 ft. high in the Susquehanna River at Conowingo, Md. The Chief of Engineers of the army has ruled that the Susquehanna at that point is a navigable stream, and it is probable that the commission will find that the project comes within federal jurisdiction.

Complaints from public utility companies concerning the delay of municipalities in exercising water-power rights probably will result in a formal opinion being rendered by the chief counsel of the commission as to whether or not cities may be granted these rights when no bond issue has been voted, no state charter issued and no approval from the voters obtained.

## Forest Service and Alaskan Development

Hutton, McNear & Dougherty of San Francisco are pressing the Federal Power Commission for a license to cover the power project on Cascade Creek, in the Tongass National Forest, in Alaska. They hold a preliminary permit covering this project, which is among the best power sites in Alaska, and are anxious to begin work in the spring.

The Forest Service has taken the position that the power rights should not be granted until the timber has been sold. Before bids can be asked for the timber, it must be cruised, or inspected, and the proposed sale advertised. These preliminaries will require until July 15 at least. Since the Forest Service is not willing to make an exception in this case, the development may be delayed a year. For the past two seasons the Forest Service has been reconnoitering the possible power sites in the national forests of Alaska, and it is cruising the timber in those areas where development is likely so as to prevent these delays. Every effort is being made by both the Power Commission and the Forest Service to co-ordinate their work, but in this particular case it seems almost certain that the applicant will have to wait.

## Iowa Engineering Society Discusses Furnace Design

Taking exception to the statement that a furnace designed to burn Iowa coal will not successfully handle Virginia or Kentucky coal—an assertion made by J. M. Drabelle in his paper before the mechanical and electrical section of the Iowa Engineering Society on "Arch and Furnace Design for Iowa Fuels"—A. T. Luce of the Des Moines city waterworks called attention to the fact that a furnace designed for Iowa coal is larger than necessary for fuel from the other states mentioned and that the tests made by the Bureau of Mines show that too large a furnace is not a detriment but merely an added expense. Mr. Luce indicated that the real trouble in using the high-heat and low-ash-value coals lies with the natural-draft chain-grate stoker, owing to the lack of ash to protect the excess grate area. He said that this difficulty is encountered with the Illinois coal to a less extent. He also explained that it has been eliminated in the forced-draft-natural-draft chain-grate stoker, which is arranged so that the grate area can be reduced and the air regulated by forced-draft equipment. In an installation under his own observation during the coal shortage it had been possible to burn successfully eastern Kentucky semi-bituminous, Colorado, Illinois and Kansas coals and Iowa "bug-dust," with slight difficulty in changing from one to the other. The heat value and ash range in these fuels was from 13,000 B.t.u. with 7.6 per cent ash to 6,430 B.t.u. with 33.4 per cent ash. Mr. Luce also declared that the chain-grate type of stoker is most effective and satisfactory with the Iowa fuels, although there are several other types working successfully. The large percentage of ash requiring constant dumping makes other types of stokers the exception rather than the rule. The low fusing point of the ash and the high sulphur content lead to clinker troubles when the fuel is agitated.

B. P. Fleming asserted that 50.7 per cent of the fuel of the country is burned in small plants that cannot afford to make changes in furnace design. He thought that the best means of increasing efficiency in these cases is the education of the firemen.

T. A. Marsh of the Green Engineering Company also called attention to the importance of the firemen as a factor in the efficiency of the boiler plant and discussed the tempering of fuel before firing in relation to combustion.

## A. I. E. E. Committee on Ship Electricians' Status

The marine committee of the American Institute of Electrical Engineers and the committee on marine electrical engineering practices of the American Engineering Standards Committee have sent a letter to the board of supervising inspectors of the Steamboat Inspection Service dealing with the status of the men aboard ship whose duty it is to maintain the electrical equipment—a matter that is becoming of increasing importance with the increase of electric propulsion. If competent men are to be obtained for this work, it is evident that they must rank as ship's officers and not simply as working electricians.

To meet this situation the committees suggest that the board establish a series of examinations leading to various electrical certificates that may be obtained by steam engineers in addition to their regular licenses, and another set of examinations leading to electrical certificates for the engineering officers of a ship fully equipped with electric power. The committees recommend further that on all ships carrying electrical officers there shall be carried in addition one or more electricians who shall have a rank comparable to that of petty officer or that of the foreman in land practice. Detailed recommendations are attached to the committee's letter

## Two Big Issues in One Day

On Thursday of last week, Feb. 1, the Alabama Power Company placed upon the market $4,700,000 in first mortgage lien and refunding 5 per cent gold bonds, due 1951, at 89½ and interest, to yield 5¾ per cent. The bonds are callable at 105 and interest, to and including June 1, 1932, and thereafter at a premium reducing one-quarter of 1 per cent per annum.

On the same day the Connecticut Light & Power Company offered a new issue of $4,500,000 in cumulative 7 per cent preferred stock at $100 per share, yielding 7 per cent.

## America's Part in London's Power Congress Unsettled

American participation in the power congress to be held in London in May of next year was to be discussed informally by representatives of the interests principally concerned at a meeting held in New York on Feb. 8. O. C. Merrill, the executive secretary of the Federal Power Commission, had asked a small group to gather on that date so that some idea might be gained as to the feeling in this country concerning American participation. Some objection has been voiced to this country's having any part in congress unless the exposition of electrical machinery and electrical products is opened to American manufacturers. Otherwise, these objectors contend, the

United States will contribute importantly to the success of the congress and will help greatly in attracting attendance at an exposition where the exhibits will be confined to articles of British manufacture. At a preliminary conference held in Washington, Jan. 30, it was suggested that the Federated American Engineering Societies should take the matter up with the promoters of the congress to ascertain the exact facts.

## New Mexico Electrical Men Adopt Program

For its ninth annual convention, to be held at Albuquerque on Feb. 12 and 13, the New Mexico Electrical Association has adopted the following program:

MONDAY, FEB. 12

*Afternoon.*—"Modern Highway Lighting," B. C. J. Wheatlake, General Electric Company, Denver; "The Power-Factor Problem," N. R. Stansel, Southwest General Electric Company, El Paso; "Utility's Place in the Industrial Field," J. E. Moorhead, Mountain States Telephone & Telegraph Company, Denver; "Method of Practical Field Testing of Transformer Loads With or Without Graphic Instruments," E. D. Stewart, Westinghouse Electric & Manufacturing Company, El Paso; "Electrical Homes," C. A. Winder, Southwest General Electric Company, El Paso; open discussion by members on general matters concerning public utility problems.

*Evening.*—Entertainment.

TUESDAY, FEB. 13

*Morning.*—"Recent Scientific Work on Coal," Prof. John D. Clark, State University of New Mexico; "The Public's Response," George E. Lewis, executive manager Rocky Mountain Committee on Public Utility Information; "Power-Plant Construction," George J. Gauthier, engineer Federal Light & Traction Company, New York; "Automatic and Remote Control of Induction Motor," Prof. R. W. Goddard, State College of New Mexico; moving pictures furnished by E. H. Waddington, Western Electric Company, St. Louis.

*Afternoon.*—"Activities of Rocky Mountain Section, N. E. L. A.," J. F. Dostal, president Rocky Mountain Geographic Division, N. E. L. A.; "Manufacture and Operation of Porcelain Insulators," R. H. Marvin, chief engineer R. Thomas & Son, East Liverpool, Ohio; "Electrical Contracting," M. Nash, Albuquerque; election of officers.

*Evening.*—Annual banquet.

## Denver Meet a Big Success

### Commercial Section N. E. L. A. Men Flock to Bureau and Committee Sessions in Mid-Continent

GREAT satisfaction with the three-day meeting of the Commercial Section of the National Electric Light Association held in Denver from Jan. 24 to Jan. 26 was expressed by the chairman of the section, Oliver R. Hogue, who said the sessions, which brought together at a point in mid-continent commercial men from all parts of the country, were the most important yet held. The attendance of 250 delegates and guests made the meetings and banquet seem more like those of a convention than like committee proceedings. An account of the opening day was contained in the ELECTRICAL WORLD for Jan. 27, page 236.

More than one hundred were in attendance at the meeting of the Merchandise Sales Bureau. The discussion centered around the possibilities of the electric range and methods of promoting electric range load. The Lighting Sales Bureau announced plans to work along two important lines during 1923—the development of the residence load and the cultivation of the store-lighting load. It was pointed out that 58 per cent of the revenue of central-station companies comes from these sources and that it is possible with benefit to the consumer to double the present lighting intensities in the home and in the store.

The Power Sales Bureau paid special attention to the problems of Western central-station companies and is to devote effort to new types of drive and control which will increase production and lower operating costs. Western men asserted that there exists a large field in the further electrification of the lumber industry and the oil wells of California. There is now 50,000 hp. in motors in use in the oil fields of that state on the lines of one central station alone. The problem of applying electric drive to the pumping of wells has been comparatively easy, but the application to drilling has not been so simple, because manufacturers do not yet produce the type of equipment necessary. The industrial heating schools started last year will be continued. It is the plan of the Power Sales Bureau to establish such schools next year in various important centers of industry in the West, working through the geographic divisions of the N. E. L. A. The manufacturers have recognized the necessity of having trained salesmen in the field and are planning to send out specialists. During 1923 the bureau will take up the study of the operating economies of uniflow and Diesel engines and will probably undertake a survey to determine the average power factor of induction motors in industrial plants in order to ascertain to what extent overmotoring is responsible for poor power factor.

#### VEHICLE BUREAU NAME CHANGED

At the meeting of the Electric Vehicle Bureau the dominant feeling was that the electric truck is now "coming into its own" as a factor in city transportation and rapidly developing into an important source of revenue for the power companies. A motion was passed at the meeting of the executive committee to change the name of the bureau to "Electric Truck and Car Bureau."

The meeting of the executive committee of the section, held on the last day, was devoted to reports from the chairmen of the various bureaus and a discussion of plans for the national convention to be held in New York in June.

The hospitality of the electrical interests of Denver was profuse and will long be remembered by the visiting delegates.

GROUPS OF DELEGATES TO N. E. L. A. COMMERCIAL SECTION MEETINGS IN DENVER

Standing, left to right—C. R. Skinner, New York; N. T. Wilson, Keokuk, Iowa; Vernon Tallman, Boston; H. S. Meese, Philadelphia; E. Praget, Schenectady, N. Y.; R. M. Bleak, Salt Lake City; R. P. Sanborn, Orange, N. J.; M. C. Morrow, New York; C. O. Dunten, Springfield, Ill.; W. L. Goodwin, New York. Sitting—J. R. Coxe, New York; F. R. Jenkins, Chicago; C. K. Nichols, New York; G. E. Miller, Cleveland; A. K. Baylor, New York; Samuel Adams Chase, New York.

Front row, seated, left to right—Harold Wright, Chicago; R. S. Hale, Boston; Oliver Hogue, Chicago; A. W. Childs, Los Angeles. Standing, left to right, L. C. Spake, Chicago; E. R. Jacobs, Chicago; C. E. Greenwood, Boston; C. A. Cummings, Chicago; James Kirk, Chicago; E. A. Edkins, Chicago; G. B. Regar, Philadelphia; A. M. Frost, Fresno, Cal.; W. E. Clement, New Orleans; D. C. Ray, H. E. Sandoval and Walter C. Heston, all of San Francisco, Cal.

## Illinois Utilities' Chicago Convention

The tentative program of the joint convention of the three Illinois utility associations to be held in the Hotel Sherman, Chicago, March 14 and 15 has been announced. The morning sessions will be joint meetings of the Illinois State Electric Association, the Illinois Gas Association and the Illinois Electric Railways Association. The annual banquet is to be held on the evening of March 14.

The tentative afternoon program for the electric association is as follows: "Survey of Appliances and Their Use in Residences in Chicago," H. B. Gear, Commonwealth Edison Company; "Thirty-Thousand-Watt High-Tension Transformer," representative of the General Electric Company; "Unattended Distributing Substations of the Commonwealth Edison Company," H. E. Wulfing, Commonwealth Edison Company; "Alternating-Current and Direct - Current - Controlled Automatic Feeder Substations," F. E. Goodnow, Public Service Company of Northern Illinois; reports of the Accounting Section of the Great Lakes Division, N. E. L. A., the committee on uniform classification of accounts and the committee on customers' records and billing; "Correct Meter Installation and the Use of Protective Devices Against Thieving," R. D. Hart, Central Illinois Light Company; symposium on merchandising: Domestic appliances, by a representative of the United Appliance Company; commercial appliances, convenience outlets and electrical homes, by E. W. Lloyd, Commonwealth Edison Company.

## Co-operation of Utility May End Holyoke Dispute

Controversy between the Holyoke (Mass.) Water Power Company and the Gas and Electric Department of that city, arising from what city officials construed as unfair competition with the city in supplying electrical energy, now appears to be approaching a settlement. In an acute fuel shortage which the city plant has lately experienced the company offered to re-establish connections between local plants and to furnish the city with energy to meet the emergency. This offer was accepted and an arrangement made for the purchase of 1,500 hp. daily from the company, to effect a saving of a carload of coal daily to the city plant. The immediate occasion of the trouble between the utility and the city was the action of local silk manufacturers in contracting with the company for a large part of their electrical energy, instead of continuing to take it entirely from the city, and the Holyoke Chamber of Commerce appointed a committee to study the merits of the controversy and seek a basis of peace.

This committee has submitted a report in which it approves of the expansion of the company, operating within its franchise rights, and suggests that it ought not to be hampered in furnishing electrical energy to any of its hydraulic power customers. The committee recommends that the connection of the city department with the company's lines be made permanent and that the city's service be developed to the limit of the possibilities of its present location. The report views dubiously the building of a new power plant by the city at a new location, believing that the larger opportunities which are being opened to New England in electric power supply can be utilized to far better advantage by the Holyoke Water Power Company than by the municipality. As the company has extensive resources in surplus hydraulic power the committee recommends that these be developed for the benefit of the community.

## Industrial Heating School to Be Held in Spring

All central-station commercial managers have received a letter from Wirt S. Scott, chairman Industrial Heating Division of the National Electric Light Association, with reference to the conduct early this spring of another central-station school of industrial heating for power engineers like the one which proved so successful last year. The Westinghouse Electric & Manufacturing Company and the General Electric Company have agreed to undertake this work again for one class each, provided that the class is sufficiently large to warrant the expense involved. The course will last two weeks. As outlined by the N. E. L. A. division, it includes lecture courses on industrial heating and high-temperature electric furnaces, a combined shop and lecture course and a shop course. The Westinghouse school will start at Mansfield, Ohio, be continued at Pittsburgh and concluded at Newark, N. J. The General Electric school will start at Schenectady, N. Y., and be concluded at Pittsfield, Mass.

This action by the Industrial Heating Division was the most important outcome of its meeting on Jan. 25, wher members from East Pittsburgh, Schenectady, Waterbury, Cleveland and Youngstown were present.

## E. H. Sniffin Talks to Western Massachusetts Engineers

E. H. Sniffin, manager of the power department of the Westinghouse Electric & Manufacturing Company, addressed the Springfield (Mass.) branch of the American Institute of Electrical Engineers Jan. 16 on "The Engineer." In the course of his remarks he said: "We are wasting more than half the 300,000,000 tons of coal we use in a year for power purposes. Many plants consuming between five and ten pounds of coal per kilowatt-hour should do the same amount of work on two pounds. Forty millions of water horsepower are yearly going to waste in this country, or double what we are now using. The problem is to utilize this power in greater volume and thus effect a vast saving in coal and the expense of hauling it from the mines. Last year the purchases in this country of steam-turbine capacity in sizes of 500 kw. and larger amounted to 10,000 hp. a day. The average size of unit was 6,500 kw. and the largest was 50,000 kw. The new electric power facilities that must be created in this country in less than ten years will exceed in extent all the facilities that exist today and which have been forty years in the making."

# Brief News Notes

**Cupples Station Company May Expand.**—St. Louis papers report the purchase of a 14-acre tract in North St. Louis, near the Mississippi River, by the Light & Development Company as a tentative site for a large supplementary power house for the Cupples Station Light, Heat & Power Company.

**New York Interests Acquire Keystone Power Corporation.** — The American Water Works & Electric Company, New York, has acquired control of the Keystone Power Corporation, which will be managed by the West Penn Power Company. The Keystone Power Corporation supplies Kane, James City, Mount Jewett, Hazlehurst, Smethport, Ridgway, Johnsonburg, St. Marys and Kersey, together with smaller places in western Pennsylvania.

**New Hood River Plant.**—The new 10,000-hp. hydro-electric plant of the Pacific Power & Light Company on the Hood River, near the town of the same name in Oregon, will be completed and placed in operation by March, according to the present estimate of the company. This plant, which will cost approximately $1,250,000, will be tied in with the Condit hydro-electric plant of the Northwestern Electric Company on the opposite side of the Columbia River.

**Quick Recovery from Substation Fire.**—Approximately seven and one-half days after the recent fire which caused damage to the amount of $50,000 to the Eagle Rock switching station of the Southern California Edison Company all impediments to the distribution of power were removed and the system was on a physically normal basis. Men of the Edison company's engineering and repair departments worked day and night to bring this about.

**Genesee Light & Power Absorbs Le Roy Company.**—All the outstanding stock of the Le Roy (N. Y.) Hydraulic Electric Company has been purchased by the Genesee Light & Power Company of Batavia, N. Y., and the latter company is now operating the Le Roy plant. As soon as a transmission line from Batavia to Le Roy can be built the operation of the Le Roy steam plant will be discontinued and the city will be served with Niagara power from Batavia.

**Municipality to Take Over Central-Station Plant.**—The city of Rice Lake, Wis., is to take over the local light and power plant belonging to the Wisconsin-Minnesota Light & Power Company. A price of $233,000 has been set on this plant by the Wisconsin Railroad Commission. This action is in accordance with a popular vote taken in August, 1920, when a majority of more than three to one favored the proposal. The plant has been furnishing electric light and power for thirty years.

**North Penn Merger.**—The Blossburg (Pa.) Electric Light & Power Company and the Mansfield (Pa.) Electric Company, together with seventeen other small electric service companies, have been merged into the North Penn Power Company, to be operated and managed by Gannett, Seelye & Fleming, consulting engineers, Harrisburg. It is proposed to develop this territory extensively. The fiscal agents for the North Penn Power Company are Jay N. Schroeder & Company, who have been in the investment banking business in Lancaster for eighteen years.

**Eastern Connecticut Buys Danielson Property.**—Papers have been signed looking toward the acquisition by the Eastern Connecticut Power Company of Norwich of the People's Light & Power Company and the affiliated Danielson & Plainfield Gas & Electric Company of Danielson. Under the transfer of ownership the Eastern Connecticut company, which operates interconnected steam and hydro-electric plants and which is tied in with the system of the New England Power Company, will distribute energy in the towns of Killingly, Brooklyn, Plainfield, Canterbury, Griswold and Jewett City.

**Buffalo Claims Largest Outdoor Station.**—Terminal "C" of the Buffalo General Electric Company, said to be the largest outdoor station of its kind in the United States, was put into operation at Buffalo on Jan. 28 to furnish power generated by the Niagara Falls Power Company at Niagara Falls. The ultimate capacity of Terminal "C" will be 175,000 hp. Transmission is at 66,000 volts stepped down to 22,000 volts for distribution to substations. The cost of the new station was more than $500,000. The same company will complete a new service building at Niagara and Front Streets about April 1.

**Good Progress on Devon Plant.**—Construction of the new $3,500,000 power plant at Devon, Conn., for the Connecticut Light & Power Company, Waterbury, has started. The site is about three miles above the mouth of the Housatonic River and is convenient for the supply of energy throughout the Housatonic and Naugatuck valleys. Three units, with a total capacity of 75,000 kw., are first planned, and when completed the plant will have six units with a total capacity of 150,000 kw. The foundations are nearly completed. The station building proper will be of steel and hollow-tile construction and will have five 300-ft. steel stacks, each 16 ft. in diameter. The "U. G. I." interests of Philadelphia are in charge of the work.

**Bill to Promote Water-Power Development in New Hampshire.**—A bill introduced into the New Hampshire Legislature by former Governor Bass of that state provides for the selection of a site where a substantial amount of water can be stored at a moderate cost and for negotiations with owners of water-power privileges on the stream below the proposed storage reservoir with a view to making contract with such plants for the additional water to be thus provided. The plan aims to provide additional power at every plant now operating below the site of the proposed reservoir at a minimum cost and without adding anything to the public charges. Those who use the water will, by the terms of the bill, pay for the interest on the cost of development, maintenance and operation and in addition they will pay off the principal within a period of fifty years. At the end of that time, the reservoir and water rights will be owned by the state free and clear.

## Associations and Societies

**Sacramento Valley Electric Society.**—An association under this name has been organized at Sacramento, Cal., with more than sixty members.

**Wisconsin Engineering Society.** — Plans are now being made for the annual convention of the Wisconsin Engineering Society, to be held in Madison, Feb. 22-24.

**Pennsylvania State Association of Electrical Contractors and Dealers.**—The eleventh annual meeting of this association will be held in Lancaster, Pa., on Wednesday, Feb. 28. Among the chief features will be an "electric open forum" designed to bring contractor-dealers into consultation with representatives of other branches of the industry.

**Supply Jobbers to Meet in Chicago.**—The regular quarterly meeting of the Central Division of the Electrical Supply Jobbers' Association will be held at the Sherman House, Chicago, on Tuesday and Wednesday next week, Feb. 13 and 14. The two morning sessions will be open, while the afternoon session on Tuesday will be devoted to an executive meeting.

**Electric Power Club.**—The next annual meeting of the Electric Power Club will be held on June 11 to 14 at the Homestead, Hot Springs, Va., where this association was organized in 1908. It is expected that important standardization of electric power apparatus will be effected at the coming meeting, because the new edition of the Electric Power Club handbook will be published soon thereafter and the different sections of the club are eager to get their work into this book.

**New York Section, I. E. S.**—On Thursday, Feb. 15, Dr. Clayton H. Sharp, will talk on "Observations in Europe" and F. V. Magalhaes will comment on the international standardization of Edison lamp bases and sockets before this section of the Illuminating Engineering Society in the auditorium of the Consolidated Gas Building. Dr. Sharp and Mr. Magalhaes were delegates to the International Electrotechnical Commission meeting at Geneva.

**Gilchrist to Address New England Merchandisers.**—John F. Gilchrist, vice-president Commonwealth Edison Company, Chicago, is to address the first luncheon meeting of the Merchandising Bureau of the New England N. E. L. A. Commercial Section at the Boston City Club, Feb. 14, at 12:30 p.m. His subject will be "Merchandising and Merchandising Conditions." The bureau will hold three or four other luncheon meetings before midsummer, the schedule calling for an address at the Bond Hotel, Hartford, March 14, by A. G. Kimball, president Landers, Frary & Clark, and one by H. A. Lewis of *Electrical Merchandising*, on "Compensation of Salesmen," at the Congress Square Hotel, Portland, Me., May 16.

---

### Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

New Mexico Electrical Association—Albuquerque, Feb. 12-13. C. E. Twogood, Albuquerque, N. M.

Electrical Supply Jobbers' Association—Central Division, Chicago, Feb. 13-14; Atlantic Division, New York, Feb. 14; executive committee and general meeting, Hot Springs, Va., May 21-25. Franklin Overbagh, 411 S. Clinton St., Chicago.

American Institute of Electrical Engineers—New York, Feb. 14-16. F. L. Hutchinson, 33 West 39th St., New York.

American Electric Railway Association—Washington, D. C., Feb. 16. J. W. Welsh, 8 West 40th St., New York.

American Institute of Mining and Metallurgical Engineers—New York, Feb. 19-21.

Wisconsin Engineering Society—Feb. 22-24. L. S. Smith, College of Engineering, Madison.

American Physical Society—New York, Feb. 24; Washington, April 21. D. C. Miller, Case School of Applied Science, Cleveland.

Pennsylvania State Association of Electrical Contractors and Dealers—Lancaster, Feb. 28. M. G. Sellers, 1518 Sansom St., Philadelphia.

Oklahoma Utilities Association—Oklahoma City, March 12-14. O. D. Hall, 1106 First National Bank Bldg., Oklahoma City

Southwestern Division, N. E. L. A.—Oklahoma City, March 14-16. S. J. Ballinger, San Antonio Public Service Co., San Antonio, Tex.

Illinois State Electric Association—Chicago, March 14-15. R. V. Prather, 305 Mine Workers' Bldg., Springfield, Ill.

Wisconsin Utilities Association—Milwaukee, March 22-23. John N. Cadby, 445 Washington Bldg., Madison.

Tri-State Water and Light Association—Birmingham, April 17-20. W. F. Steiglitz, Columbia, S. C.

American Electrochemical Society—New York, May 3-5. Colin G. Fink, Columbia University, New York.

Southwestern Public Service Association—Fort Worth, Tex., May 15-17. E. N. Wills, 403 Slaughter Bldg., Dallas, Tex.

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

Electric Power Club—Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

Pacific Coast Electrical Association—San Francisco, June 19-22. S. H. Taylor, 527 Rialto Bldg., San Francisco.

# Recent Court Decisions

**Rate-Fixing Procedure of New Jersey Commission.**—Reversing on a writ of certiorari an order of the Board of Public Utility Commissioners of New Jersey (Hackensack Water Company vs. Commissioners), the Supreme Court of New Jersey held that the board must take the present value as the value of property devoted to public use and may not arbitrarily take the average for the two preceding years, notwithstanding the making of valuable improvements in the second of such years. Moreover, the board must take into consideration deficiencies in earnings accumulated during a series of years under and due to prior insufficient rates fixed by the board. (119 At. 84.)*

**Contributory Negligence in Relation to Linemen.**—In Elliott vs. Water, Light & Transit Company damages were sought for the death of a workman of little experience who was killed while engaged in stringing and connecting transmission wires in Keytesville, Mo., because the current was not cut off and some of the wires were uninsulated. The trial court refused to instruct the jury to render a verdict for the defendant on the ground of contributory negligence, and the jury found for the plaintiff. The Kansas City Court of Appeals has now reversed this finding and ordered a new trial, but on purely technical grounds connected with a defect in the original petition. (245 S. W. 568.)

**Presumption Is That Franchise Rates Are Reasonable.**—Although a city and a utility company are powerless to make an irrevocable contract as to rates, yet the rate specified in the franchise, in the absence of negative allegations, will be presumed to be a reasonable rate for the purpose of considering the sufficiency of a complaint on demurrer, and on a hearing of a motion for a temporary injunction a like force will be given to such specified rate, in the absence of affidavits tending to show that it is unreasonable. This was the finding of the Supreme Court of South Dakota in an action brought by the city of Mitchell against the Mitchell Power Company to prevent it charging a rate for gas in excess of the maximum franchise rate. (190 N. W. 1013.)

**Employer Not Liable for Injury from Explosion of Electric Light Bulb.**—Sustaining a non-suit in Russell vs. St. Louis & San Francisco Railway Company, the Springfield (Mo.) Court of Appeals found the company not liable for an injury to the eye of the defendant caused by the explosion of an electric light bulb from which he got light on his work. The doctrine of *res ipsa loquitur* (the thing speaks for itself) was held not to apply in the absence of allegations that employer manufactured and supplied its own electric light bulbs and the electricity to produce the light, or that an explosion would not have occurred without some negligence in the use of the bulb and electricity, or unless the construction of the bulb was faulty, since the court could not take judicial notice as a matter of common knowledge that an electric light bulb will not explode except as the result of negligence. (245 S. W. 590.)

**Riparian Owners' Rights to Water Power.**—In a suit brought by the Watervliet Hydraulic Company against the State of New York to obtain compensation for lands appropriated for Barge Canal purposes and damages for such appropriation the Court of Claims of New York found that a riparian owner whose lands border on a stream the bed of which is owned by the state has no right to use the water power of the river at that point, where the only practicable method for using that power requires the construction of a dike or dam extending into the river on the state-owned lands. The owner of tracts of land on opposite sides of a river the bed of which was owned by the state, who had for many years maintained a dam across the river between those tracts without objection by the state, is not a mere trespasser, but it must be presumed the state acquiesced in the maintenance of the dam, so that the riparian owner was a licensee, and where the state, instead of requiring the licensee to remove the dam, elected to appropriate it, it must pay the owner the value of the dam, considering the fact that the owner has no right to maintain it if the state should require its removal. (197 N. Y. S. 348.)

**Property Owner Maintaining Electric Conductor Near Sidewalk Liable for Injury.**—Ruocco vs. United Advertising Corporation and United Illuminating Company was a suit to recover damages for the death of a passing pedestrian who was said to have reached over and touched a chain hanging close to the inside of the open door of the first-named defendant's garage, this chain, it was alleged, having become charged with electricity owing to the failure of both defendants to install and maintain properly the wiring and electric apparatus used in the garage. The defendants claimed that the victim was a trespasser as the chain was beyond the sidewalk and on private property, and this contention was sustained by the trial court. The Supreme Court of Connecticut has reversed the judgment and remanded the case, asserting that an owner of property abutting on a highway rests under an obligation to use reasonable care to keep his premises in such condition as not to endanger travelers in their lawful use of the highway, and that if he fails to do so, and thereby renders the highway unsafe for travel, he makes himself liable, even though the consequent injury is received upon his own land and not on the highway. (119 At. 48.)

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

# Commission Rulings

**Proper Expenditure for Extension.**—In adjusting a complaint brought against the Plaistow Electric Light & Power Company the New Hampshire Public Service Commission held that such a company should expend in making an extension an amount which would be equivalent to the total gross income from the business of the new territory for a period of three years in cases where the increase in business is doubtful and the cost of installation substantial. The estimated cost of construction, the commission said, should contemplate a free right-of-way with no expense for tree cutting or other work of a similar kind necessary in making the extension.

**Using Prospective Customers' Labor in Constructing Line.**—Passing upon an application for electric service made by would-be customers of the Utah Power & Light Company living nearly a mile from its lines, the Utah Public Utilities Commission laid down the principle that consumers at too great a distance from existing lines or having peculiar conditions of service which make them a burden upon the general consuming public may be required to share in the special investment made to serve them. The commission said: "The power company has offered to utilize the labor of these prospective consumers in the construction of the extension in so far as they are fitted for the task at hand, or, on the other hand, is willing to let the contract for the work to any competent contractor, so that it does not appear that an injustice will be done"; but it added: "To insure the safety of both the public and employees certain standards of construction must be insisted upon."

**Expenditure to Satisfy Damage Claim Arising During Construction Cannot Be Charged to Capital.**—The California Railroad Commission has denied the request of the San Joaquin Light & Power Company to be permitted to include in capital account the sum of $50,000 representing an award for property damage caused during the construction of a transmission line through the burning of a wheat field. To this plea the commission replied: "This commission estimated the rate base as the reasonable historical cost of the property, and it does not appear that the cost of paying damages for the burning of a wheat field due to conditions which were deemed by the courts as negligence can be classified as a reasonable cost of the construction of the power system. The return allowed by the commission contemplates certain hazards of the business, and it would appear that damage such as the one in question represents one of those hazards which must be borne by the stockholders of the utility company."

# Men of the Industry

Changes in Personnel
Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry

## A Man with a Vision

**An Appreciation of John B. Miller, Who Has Built the Southern California Edison Company**

TWENTY-FIVE years ago there went to southern California a man from Michigan. He had no experience in central-station operation, but he had imagination, vision, confidence, executive ability and money. He became interested in the public utility situation in that part of the country and brought about the combination of several electric light and power companies in or near Los Angeles into what later became the Southern California Edison Company. He became the president of the consolidated company at a salary of one hundred dollars a month.

J. B. MILLER

An unheard-of budget, calling for the expenditure of $50,000, had to be financed, and John B. Miller set about the task of raising this money. No man ever undertook a less promising development. For southern California was not a garden spot in those days. It was largely a desert without population, and the vision that pictured the possibilities for electrical expansion had to frame also a dream of gathering population and growing industry.

From the start Miller recognized that spiritual qualities of good service, square dealing and courteous treatment would do more than anything else to bring success to the new type of enterprise he was heading and that such an element in a community would be a great attracting force, a far-reaching appeal, that would call many people and bring them to the city he was seeking to upbuild. As the years rolled by he saw his theory proved in operation, and he continued to interpret and expound his conception of the attitude which utility officials and employees should maintain toward the public in simple words that have now become classic in the industry.

Years before the advent of regulatory commissions he instituted this policy. It is interestingly expressed by a letter that he wrote on Sept. 26, 1905, which is today held as one of the prized records in the archives of his company. He wrote:

"The Edison Electric Company desires to have the confidence and respect of the public with which it deals. Officers, agents and other employees should, in every reasonable way, endeavor to increase that confidence and respect by doing everything in their power to make the name of the Edison Electric Company synonymous in the mind of the public with good service, square dealing and courteous treatment. The public gains impression of the company through contact with its representatives, and they will, therefore, be held responsible in every instance for carrying out the well-established policy of the company—good service, square dealing, courteous treatment."

Last week men pre-eminent in the electrical industry flashed words of congratulation to Mr. Miller from every district of the country upon his completion of twenty-five years of service and as a spontaneous recognition of his success. An account of the banquet given in his honor by the other officials of the great company which he heads is contained in this week's "News of the Industry."

## W. A. Whittlesey Heads Pittsfield Company

W. A. Whittlesey has been elected president of the Pittsfield (Mass.) Electric Company to succeed the late Alexander Kennedy. Mr. Whittlesey has been general manager of the company for some years past and is well known in the New England central-station field. Most of the expansion of the company's plant and service during the last decade has been under his immediate direction, including the reconstruction of the Silver Lake generating station, the arrangement of an interconnection now under construction between the Pittsfield system and that of the Turners Falls Power & Electric Company in the Connecticut Valley, and the development of an active commercial policy in electrical and merchandising sales in the upper Housatonic Valley.

**Karl Smith** has left Grafton, N. D., and is succeeded by E. W. Steinbuck, formerly at Kasson, Minn., as superintendent of the Grafton plant.

## A. C. Marshall Assumes Office of General Manager

Alfred C. Marshall, vice-president of the Detroit Edison Company, became vice-president and general manager of the company on Feb. 1, succeeding Alex Dow in the office of general manager. Mr. Marshall and Mr. Dow have been intimately associated since 1894, when Mr. Marshall allied himself with the public lighting commission, which under the direction of Mr. Dow was building the first public lighting plant erected in Detroit.

In 1899 Mr. Marshall left the commission to become chief engineer of the "rapid railway" system which was under construction between Detroit and Mount Clemens. In 1903 he again became associated with Mr. Dow upon joining the Edison Illuminating Company, planning and superintending construction. Two years later he went to Port Huron to take charge of the electric light plant. A stay of six years in this city gave him valuable training in all phases of the electric light business. In 1911 he rejoined the Detroit Edison Company and later was elected a vice-president and director of the company.

A. C. MARSHALL

Mr. Marshall has been active in association work as secretary and treasurer of the Michigan Electric Association from 1905 to 1910 and as its president in 1911, when it was converted into the Michigan State Section of the National Electric Light Association. Mr. Dow retains his duties as president and chief executive of the Detroit Edison Company.

**G. W. Barker**, electric range expert of the San Francisco division of the Pacific Gas & Electric Company, has been promoted to the position of domestic-appliance sales engineer.

**J. E. Harsh**, general manager of the Lincoln (Neb.) Gas & Electric Light Company, has been placed in charge of the Virginia Power Company, a subsidiary property of the Doherty interests. Mr. Harsh has been in charge of the Lincoln plant for a period of more than five years.

## F. L. Butler Elected Vice-President of Georgia Company

Frank L. Butler, general operating manager of the Georgia Railway & Power Company, has been elected a vice-president, in charge of operation. Mr. Butler has been associated with the company since February, 1921, when he became the manager of its railway department. One year later he was made general operating manager in charge of the railway, electric, gas and steam-heating departments. For three years previous to his assuming the managership of the Atlanta's company railway department Mr. Butler was connected with the Winnipeg (Man.) Electric Railway, and he was manager of that property when he tendered his resignation to go to Atlanta. Mr. Butler was born in Terre Haute, Ind., in 1874 and at the age of twenty entered the employ of the Vandalia Railroad. Subsequently he was connected with the Denver & Intermountain Railway, the Alton, Jacksonville & Peoria Railroad and the Chicago & West Towns Railway.

F. L. BUTLER

**Dudley Sanford**, industrial engineer with the Union Electric Light & Power Company, has recently been appointed assistant treasurer of that company and treasurer of the St. Louis County Gas Company.

**J. K. Leibing** has severed his connection with the Great Western Power Company of California to take a position in the general engineering laboratories of the General Electric Company at Schenectady, N. Y.

**T. L. Nudd**, former electrical engineer with the Newbery Electric Corporation of Los Angeles, in charge of estimating and engineering, has been made electrical engineer for the Allied Architects of Los Angeles to supervise inspecting and estimating. Mr. Nudd is a graduate of the University of California and previous to his connection with the Newbery Corporation he was electrical inspector in the Bureau of Yards and Docks, Navy Department, at the San Diego public works office.

**A. C. Schloth** has resigned as assistant electrical engineer for the General Electric Company at Lynn, Mass.. and is devoting all of his time to patent work.

**J. Elmer Housley** has been recalled to his former position as electrical engineer with the Aluminum Ore Company, East St. Louis, Ill. For the past year he has been in the sales department of the Aluminum Company of America at Kansas City.

**Thomas J. Rabbitt**, who has been associated with the Cape & Vineyard Electric Company, Vineyard Haven, Mass., for about six years, has recently been appointed assistant manager of the company, and Theodore Chaffin, who has been in the company's service about nine years, has been appointed assistant treasurer.

**F. R. Kohnstamm**, who has been acting manager of the domestic heating section of the merchandising department of the Westinghouse Electric & Manufacturing Company, has been made manager of the section, and E. W. Knight, who has been acting manager of the fan section of that department, has been appointed manager of that section.

**W. G. Church** of Wichita Falls, Tex., formerly of Farmersville, in the same state, has been appointed general manager of the Electra (Tex.) Light & Power Company, succeeding E. D. Kelly, resigned. Mr. Church has been connected with the Mid-West Utilities Company, owner of the Electra plant, for about five years, including a period of service before the war.

**A. E. Blackwell** of Denver, Col., has arrived in Sedalia, Mo., to take up the duties of W. M. Little, of the distribution department of the City Light & Traction Company in Sedalia. Mr. Little has been promoted to the business department. Mr. Blackwell has been doing for the Henry L. Doherty Company in Denver similar work to that which he is now undertaking.

**Morgan Brooks**, professor in the department of electrical engineering of the University of Illinois, who is touring Europe on a year's leave of absence from his duties, addressed a convention of Italian electrical engineers held in Rome in January. His topic was the investigation of the fatigue of metals which is now being conducted by Prof. H. F. Moore of the department of theoretical and applied mechanics of the University of Illinois. Stereopticon slides and Professor Moore's motion-picture films were shown. Professor Brooks gave the same lecture before engineers at Prague, Czechoslovakia, in December, on the personal invitation of the President of that republic, following reports from other localities of the interest he had aroused in engineering circles. The international co-operation of engineers exerts a stabilizing influence on the unsettled world conditions, in the opinion of Professor Brooks, who reports great interest abroad in American engineering and educational progress.

## B. L. Worden Succeeds Mr. Berresford

At the annual meeting of the Cutler-Hammer Manufacturing Company of Milwaukee, held Jan. 25, B. L. Worden, president and general manager of the Beaver Board Companies, was elected a director and vice-president to fill the vacancy created by the resignation of A. W. Berresford. Mr. Worden was the organizer and president of the Worden-Allen Company of Milwaukee and the Lackawanna Bridge Company of Buffalo, which interests he has recently disposed of. During the late war he was general manager of the shipbuilding department of the Submarine Boat Corporation, and it was under his supervision that the shipyard at Newark Bay was built.

B. L. WORDEN

**Wiley F. Corl**, general manager of the Missouri Utility Company, Mexico, Mo., has been elected president of the Mexico Chamber of Commerce.

# Obituary

**Albert Brown Chandler**, formerly president of the Postal Telegraph Company, died at his home in Randolph, Vt., on Saturday, Feb. 3. Mr. Chandler, who retired many years ago, was eighty-three years of age.

**E. T. Nye**, general manager of the West Jersey Electric Company and Five Mile Beach Electric Railway Company, died on Jan. 30 at his home in Wildwood, N. J. Mr. Nye had been with these companies for sixteen years and before filling his post at Wildwood had charge of the electric light company in Pleasantville, N. J.

**John Warren Sargent**, a widely known designer and builder of stationary engines and junior member of the former firm of Rice & Sargent, Providence, R. I., died at Providence on Jan. 30. During the past few years Mr. Sargent had devoted himself mainly to research work in connection with prime movers. He was born at Amesbury, Mass.

# Manufacturing and Markets

Devoted to the Discussion of Business and Economic Problems of the Producer and Distributor, with Market Reports, Trade Activities, Foreign and Construction News

## Price, Selling Cost and the Non-Electrical Distribution*

By W. R. Herstein
Vice-President and General Manager
Electric Supply Company, Memphis, Tenn.

WE HAVE now reached a point in the wholesaling of electrical supplies where, in my opinion, a well-defined issue presents itself to the jobber. This plain, clean-cut issue is, Shall we continue to accept business wherever offered or shall we endeavor to confine our own particular lines to customers who will co-operate with us in the endeavor to keep quality above price, and to pass the product into the hands of the user through the medium of intelligent salesmanship?

### Price the Chief Interest

My first impression in attempting to sell to the non-electrical dealer was that he had little or no regard for quality, which I had been trained almost to reverence, but was chiefly interested in price. He simply knew nothing regarding electrical devices and was not qualified to judge between good and bad. Subsequently, however, he did become qualified, but his interest in price remained unabated, because he was now selling electrical devices at very low prices, as a leader, to draw trade to his store. Furthermore, in order to sell to him, our maximum discounts, regardless of quantity, were demanded, because he was a subscriber to a purchasing syndicate in New York, and if we would not sell him on his own terms, the business went to the syndicate. Still further, his practice of cutting the price on nationally advertised articles caused dissatisfaction on the part of our other dealers in that particular town, and when he advertised these prices in a newspaper that had a state-wide circulation the dissatisfaction extended to our dealers throughout the state.

You will note that I have not said whether this dealer was a department store, grocer, druggist or hardware dealer. He might have been, and in the course of time was, either one or all of them. Then this curious thing began to happen: Some of my local friends who are jobbers in other lines began asking me about the electrical jobbing business. Their interest, they frankly stated, was aroused by requests from their customers—whom I had foolishly begun to believe were mine—that they should carry in stock certain devices such as dry batteries, flash-lamps, incandescent lamps, etc., which they had theretofore been buying from electrical jobbers, but which they preferred getting with other goods from their main source of supply. Here, therefore, was another more or less formidable legion of competitors — competitors, too, knowing nothing of the traditions of the trade. And since the manufacturers of inferior electrical devices are not going out of business, let me recommend to the makers of higher-grade goods that they let the low-grade manufacturer take the non-electrical jobber's business and refrain from forcing his attentions upon the strictly electrical jobber

### Qualifications of Contractor

It will be easily inferred that my own judgment in the choice of retail distributors points unqualifiedly to the electrical man. I have intimated the necessity for technical knowledge in salesmanship, but have not enlarged upon this point because the non-electrical dealer can easily hire help of this character. As a matter of strict fact, we know that he seldom does, but my main objection to him may be summed up in the expression that he is too close, if not absolutely unfair, in buying; he has too little regard for quality, and he does not remain permanently the electrical jobber's customer. I do not accuse him of inability in the matter of servicing goods sold, but he is frequently as indifferent in this respect as he is in the matter of hiring qualified salesmen.

The principal criticisms of the electrical contractor as a retailer are:

1. He is not a merchant and, by inference, never will be one.
2. His credit rating is, as a rule, unfavorable.
3. He is lacking in aggressiveness.

It has been said that the majority of electrical contractors and dealers fail. Granting, solely for the sake of the argument, that this is true, it is not the failures that I am talking about, but the successes.

### Discounts Too Small

If there is any great degree of reason for the charge of inefficiency and incompetency against the electrical retailer, there is abundant defense to be introduced in his behalf. The retailer has never been treated fairly in the matter of remuneration, and he has frequently been subjected to crushing competition by the very jobbers who condemn him. He has been asked to maintain a high-class establishment, frequently in the heart of the high-rent district, with well-paid, neatly dressed, skilled and technical salesmen, and to pay for this out of a commission of 20 to 30 per cent, when his neighboring retailers in other lines receive more than double for services of the same, or less efficient, character.

In recent years sympathy for the retailer has increased, and the conviction has gradually been forced home to jobbers and manufacturers that if this class of customer is to survive at all, fairer treatment must be accorded him. His discounts are slowly but surely creeping through the "thirties" and up to 40 per cent. Nothing less than 40 per cent on ordinary lines will ever save the situation for the electrical retailer. He is no more of a miracle worker than retailers in other lines, and if they must have it, so must he. On specially difficult lines, such as

*From an address before the winter meeting of the Electrical Supply Jobbers' Association, Cleveland.

motor-driven devices, even better than 40 per cent must be given him if he is both to market the device and service it six months or a year without additional compensation.

### COST OF MARKETING

Forty per cent for the retailer, with reasonable compensation for the jobber, means that the jobber and dealer are to receive as much for selling the device as the manufacturer gets for making it. At first blush, it might seem that here is fine political capital for the well-known case of the People versus the Middleman, but a cold and dispassionate analysis of the evidence shows differently.

So long as the public will not go to Pittsburgh for its steel, just so long must steel products be kept on display in retail stores from Maine to California. And so long as the people will not go into the outskirts of the city or its manufacturing and wholesale districts to make their purchases, just so long must the retailer remain in the high-rent district at the expense of the people. Many things combine to make the task of marketing difficult, and who shall say that the man who sells does not do as good a job as he who makes? Shall he not, then, be entitled to equal compensation?

Thus far I have said little or nothing regarding the central station's part in the retail business. Until recent years the central-station idea was that the devices were to be sold for the purpose of creating an off-peak load, and that profit from sales of the devices themselves was of no consideration. Only recently has it become an accepted theory that the merchandise itself must pay its own way, and here the central station has found its position superior in no way to that of the ordinary retailer, so far as overhead expense goes.

### MANUFACTURING EFFICIENCY NEEDED

To summarize the situation, I should say that the jobber is in the industry permanently; that he can handle these lines most economically through the electrical contractor-dealer and, to a limited extent, through the central station. I would say that whoever retails electrical appliances will have to be paid a price commensurate with the work done and the expense involved; that if, after according the jobber and retailer their necessary remuneration, the public will not pay a retail price that leaves the manufacturer a profit, then the manufacturer must become more efficient. Ours is a comparatively new industry, and perhaps our manufacturers still have something to learn.

An electric range, for instance, ought not cost half as much as a Ford automobile. The rugged structure of a 16-in. desk fan ought not cost twice as much as the delicate mechanism, assemblage and calibration of a 5-amp. wattmeter. A coffee percolator should not cost as much as it takes to ship a thousand pounds of them a thousand miles. The jobbers have recently given largely of their time and money to ascertain their own cost of operation and have gladly welcomed the offer of the manufacturers to police this investigation. Would the converse hold good, and may we some day see the manufacturers investigating their own costs with the steadying influence of jobber supervision over the work?

And, finally, would it not be well for both jobber and manufacturer to realize that their interest in an electrical appliance is not ended until it reaches a satisfied consumer, and that satisfied consumers will come only through satisfactory retailers?

# Competition in the Heating Line

**A Few Reflections on the Influence of Business Rivalry—Reasons Why We Need Not Fear Though Patent Bars Are Down**

BY THOMAS C. RUSSELL
President and General Manager
Russell Electric Company, Chicago, Ill.

T. C. RUSSELL

WE WHO are in the business of manufacturing electrically heated appliances are apt to forget when we contemplate the expiration of the Marsh patents this month that competition does us good. The Japanese people probably owe their sturdiness and perseverance largely to the fact that they have lived for ages in a land which, except for about one-eighth of its area, is all cruel mountains. Combat strengthens manhood. I believe it was Theodore Roosevelt who said, "The highest type of man that civilization has produced is a fighting man."

So it is in the field of manufacture. Competition is sometimes destructive, but it certainly sharpens the wits and forces progress in the art and in the industry.

My company for some years has been manufacturing a number of moderate-priced electric heating specialties in competition with the established older, higher-priced lines. Our business has been developed in the face of the keenest competition with well-organized and amply financed concerns of large experience. We have found ways to manufacture quality products at lower than prevailing costs and therefore have been able to sell at very moderate prices. Out of this has come a distinct stimulus to all the manufacturers of these goods, and the public today has a better curling iron, a better grill and better values in other specific appliances than it would have if no competition had impelled us all to eagerness to better our product and reduce the cost. Easy money has ruined many a good business.

There is only one kind of competition that any manufacturer, jobber or dealer in heating appliances need fear—devices that are made for price only and without regard to quality. But such competition is always temporary. In a little while the dealer who sells it finds his customers complaining and he learns his lesson. For it is good will that makes business for the manufacturer, the jobber and the dealer.

The man who starts to sell cheap

stuff makes money, but he loses customers and he soon finds that it costs him more than he makes. Quality is not just a moral obligation; it is a business necessity. If the goods fall down, the woman who owns them looks to the dealer for protection, the dealer looks to the jobber, and the jobber falls back on the man who sold to him, and the business crumples up. We all have a responsibility to prevent the sale of dangerous appliances, but competition in the production of a reliable product is a good thing for us all.

The American people want a guarantee that stands permanently behind the goods and a price that pays an ample profit, but shares with them the benefits of low cost. They know that the man who does not make sufficient on his goods to prosper cannot provide for the protection of his customers, and without this he cannot succeed.

#### TO PROSPER THE FIRST DUTY

It is the first duty of the manufacturer, therefore, to prosper by conducting his business on an economic basis so that his costs may be low and so that he can sell at a reasonable price. If he does this he need not fear competitors. For if he cannot make good merchandise and compete with other men selling good products, at a good profit, he has no right to occupy the stage.

Many men feel that the methods and policies under which they run their business enterprises are entirely their own private affairs, but this is not the case. The prices at which they and their competitors sell their goods are a matter of concern to the industry. It is good business methods that make possible low cost, and it is low cost that makes possible low price. The way the manufacturer of heating appliances conducts his business, therefore, has a lot to do with his ability to meet the more active competition that will undoubtedly come now that all bars are down. Nobody will be able to come in and overnight learn all the kinks of the busines. The losses which the experienced manufacturers have had to stand from time to time are witness to the fact that the newcomers will find it a hard field to work. It will take time for them to learn both their product and their market.

In the meantime it behooves the present manufacturers to look to their efficiencies, not alone in manufacturing but in selling. They must recognize the fact that good customers must not be undermined by selling "fly-by-nights." It is possible to combine an easy credit policy and stiff collections or stiff credits and easy collections, but easy credits and easy collections do not go together. Full financial responsibility right down the line is absolutely vital to permanent success.

# Business Conditions

A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand

## Electric Refrigeration Faces Active Season

Owing to unusually snowy weather without periods of extreme cold of sufficient length to form a normal ice crop, many localities in the North and East will furnish remarkably good markets for electric refrigerating equipment during the coming spring and summer. In New England the alternation of snow with warm rains has resulted in the formation of ice of inferior quality and abnormally small thickness. Many cases have occurred where the ice ponds have been cleared of snow only to have these labors rendered vain by the arrival of another storm before harvesting could take place. Predictions are that the ice crop will be small and next summer's prices high. Manufacturers of refrigerating equipment are working hard in preparation for this business, and vigorous efforts are in prospect by central stations and contractor-dealers to cultivate this class of service through intensive advertising and solicitation.

## Increase in Use of Electric Signs in England

A noticeable increase in the use of electric signs for advertising purposes is taking place in England, according to reports to the United States Department of Commerce. The development of this means of public display, however, in no way approaches that of cities of similar size in the United states. Usually they consist only of an illuminated word or two concerning the firm or the product advertised. Some are lighted continuously and others flash off and on. Only in a very few instances are colored lights used, and the result is not particularly effective.

## Number of Delinquent Electrical Accounts Increases

The delinquent electrical account report prepared by the Electrical Credit Association has Chicago in the lead with 1,104 accounts for December, 1922. This is a gain of 291 over November, but a lower average amount by $48.18. Compared with November and December, 1921, the December, 1922, account is lower by 53, but an increase in value from $107.49 to $125.84.

New York is next on the list, with 485 old accounts in December, 1922, as against 434 in December, 1921, with a respective average value per account of $193 and $136. The gain over November, 1922, is 96 accounts, but a decreased average value of $25. The list of accounts is as shown below:

VALUE AND NUMBER OF DELINQUENT ELECTRICAL ACCOUNTS

| Branch and month | Number of Delinquent Accounts Reported | Total Amount | Average Amount |
|---|---|---|---|
| Central Division: | | | |
| November, 1921 | 1,111 | $142,209.09 | $128.00 |
| November, 1922 | 813 | 141,482.10 | 174.02 |
| December, 1921 | 1,157 | 124,376.98 | 107.49 |
| December, 1922 | 1,104 | 126,342.89 | 125.84 |
| New York: | | | |
| November, 1921 | 328 | 57,550.00 | 173.00 |
| November, 1922 | 389 | 84,743.00 | 218.00 |
| December, 1921 | 434 | 58,840.00 | 136.00 |
| December, 1922 | 485 | 93,428.00 | 193.00 |
| Philadelphia: | | | |
| November, 1921 | 202 | 26,540.09 | 131.43 |
| November, 1922 | 215 | 24,703.46 | 114.90 |
| December, 1921 | 186 | 28,992.97 | 155.87 |
| December, 1922 | 183 | 19,307.58 | 105.51 |
| New England: | | | |
| November, 1921 | 68 | 7,912.95 | 116.37 |
| November, 1922 | 47 | 6,130.29 | 130.43 |
| December, 1921 | 44 | 8,484 25 | 192.82 |
| December, 1922 | 34 | 3,809,68 | 112.05 |
| Pacific Coast: | | | |
| November, 1921 | 16 | 1,054.82 | 65.92 |
| November, 1922 | 24 | 4,117.10 | 171 54 |
| December, 1921 | 23 | 2,667,74 | 107.72 |
| December, 1922 | 14 | 2,225.43 | 158.90 |

## Comparative Prices of Station Supplies

| | Current Price | Four Weeks Ago | One Year Ago |
|---|---|---|---|
| Soft steel bars, per lb. | $0.030 | $0.0295 | $0.0271 |
| Cold finished shafting, per lb. | 0.0385 | 0.0378 | 0.0333 |
| Brass rods, per lb. | 0.1742 | 0.171 | 0.155 |
| Solder (half and half), per lb. | 0.2425 | 0.24 | 0.2075 |
| Cotton waste, per lb. | 0.1175 | 0.11 | 0.106 |
| Washers, cast iron (½-in.), per 100 lb. | 4.33 | 4.33 | 3.65 |
| Emery, disks, cloth, No. 1, 6-in. diameter, per 100 | 2.96 | 3.11 | 3.11 |
| Machine oil, per gal. | 0.36 | 0.36 | 0.40 |
| Belting, leather, medium, off list | 49% | 30-10%@50% | 46% |
| Machine bolts, up to 1-in. x 30-in., off list | 51⅓% | 55%@60% | 64¼% |

## Vacuum Cleaner Sales Increase 15 to 25 per Cent in Six Months

Although this time of the year is generally known as a dull season for vacuum cleaners, manufacturers of grades featured in the larger of the advertising campaigns report increasing sales. These increases range from 15 to 25 per cent heavier than six months ago, which was a season that required less sales effort. Deliveries generally are normal, in some cases it having been necessary to carry on overtime work in order to keep up with orders. Some of the makers of quality cleaners who at the present time report increases in sales ranging from 15 to 20 per cent state that they are confident that their business will grow 15 per cent more during the next half year if their present intensified sales efforts are continued.

## Wholesome Growth in Radio Industry

David Sarnoff, vice-president and general manager of the Radio Corporation of America, believes that the growing increase in sales of complete sets is one of the most wholesome signs of progress that have yet been seen in the radio industry.

"Amateurs who are really young experts have succeeded in putting together sets that have given very creditable results," Mr. Sarnoff said. "They have understood every feature of such a set, operating it with expert knowledge and affectionate regard. Complete sets, however, embody the research and skill of America's foremost radio engineers. From these complete sets the amateurs are obtaining amazing results when conditions are right.

"No one ever dreamed when radio was first discussed that it would be possible to manufacture a home receiving set at a cost that makes possible the low prices now prevailing. The development of manufacturing processes has tended steadily toward simplification, and whereas at the beginning the sales were mainly among the amateurs, the public generally is now beginning to install radio receiving sets.

"There has been a growing appreciation of the fact that expert knowledge is not needed when complete sets are bought. The first big rush of buying came from the amateurs. When this first big demand was supplied there was a noticeable tendency on the part of dealers to wonder why sales had fallen off.

"As a matter of fact, the radio industry had really reverted to normal. It had established itself upon a regular merchandising basis. The increase in business, which began in September, was based upon a growing appreciation by the general public that radio is here to stay and broadcasting is here to stay.

"The growing increase in the sale of complete sets is one of the most wholesome signs of progress that have taken place in the radio industry. It means that the merchandising phase has arrived and is on a sound basis."

## Electrical Exports in 1922 Were $63,213,838

Electrical exports from the United States during the year 1922 amounted to $63,213,838, according to the Bureau of Foreign and Domestic Commerce of the Department of Commerce. This figure shows a falling off of $32,601,047 from the figures of 1921, when exports amounted to $95,814,885, and a falling off of $38,776,166 from the figures for 1920, when they amounted to $101,990,004. Electrical exports for December, 1922, and for the years, 1920, 1921 and 1922 are as follows:

ELECTRICAL EXPORTS FOR THE YEAR 1922

| Articles | Value: December, 1922 | Value: Total Year 1922 |
|---|---|---|
| Turbines | $99,335 | $1,720,480 |
| Generators | | |
| Direct-current— | | |
| Under 500 kw. | 50,446 | 535,501 |
| Over 500 kw. | 62,684 | 998,975 |
| Alternating current— | | |
| Under 2,000 kva. | 29,000 | 290,668 |
| Over 2,000 kva. | 360,556 | 1,412,262 |
| Accessories and parts for generators | 20,994 | 1,135,736 |
| Self-contained lighting outfits | 28,701 | 441,569 |
| Batteries | | |
| Primary, dry | 90,928 | 1,047,093 |
| Primary, wet | 391 | 35,992 |
| Storage | 133,300 | 1,473,560 |
| Transforming and converting apparatus: | | |
| Transformers, power | 247,103 | 4,158,798 |
| Transformers, other | 78,011 | 747,324 |
| Rectifiers | 12,361 | 61,208 |
| Condensers, double-current and motor-generators, dynamotors, synchronous and other converters | 51,224 | 1,305,200 |
| Transmission and distribution apparatus: | | |
| Switches and panel-boards, except telephones | 259,977 | 2,701,508 |
| Switches and circuit breakers | 166,546 | 1,891,921 |
| Fuses and fuse plugs | 24,978 | 198,665 |
| Meters and measuring instruments: | | |
| Watt-hour and other measuring instruments | 52,602 | 564,476 |
| Volt, watt and ampere meters, and other recording, indicating and testing apparatus | 141,322 | 876,453 |
| Lightning arresters, choke coils, reactors and other protective devices | 100,970 | 678,438 |
| Motors, starters and controllers: | | |
| Motors under 1 hp. | 77,059 | 772,433 |
| Stationary motors— | | |
| 1 to 200 hp. | 212,300 | 2,037,231 |
| Over 200 hp. | 45,386 | 665,967 |
| Railway motors | 89,743 | 480,149 |
| Electric locomotives | | |
| Railway | 140,703 | 853,562 |
| Mining and Industrial | ....... | 224,645 |
| Other motors | 6,389 | 351,384 |
| Rheostats, controllers and other starting and controlling equipment | 159,949 | 920,118 |
| Accessories and parts for motors | 86,377 | 1,138,241 |
| Electrical appliances: | | |
| Electric fans | 92,009 | 816,116 |
| Electric lamps: | | |
| Arc | 842 | 21,115 |
| Incandescent— | | |
| Carbon-filament | 8,927 | 62,393 |
| Metal-filament | 89,380 | 1,224,630 |
| Other electric lamps | 19,617 | 184,421 |

| Bare wire | 135,065 | 1,875,422 |
| Insulated wire and cable | 175,728 | 1,982,093 |
| Total electrical machinery, apparatus and appurtenances | $5,836,391 | (1922) $63,213,838 |
| (1921) | 5,177,276 | (1921) 95,814,885 |
| (1920) | 13,812,180 | (1920) 101,990,004 |

## New England's Growing Volume of Business Helping Collections

Collections in New England are responding to the growing volume of business in manufacturing and jobbing circles, and continued favorable terms for money are helping to restore more stable conditions in the electrical field. Representative houses are rounding up their accounts in an average of fifty-eight to sixty days, although some outstanding paper is not taken care of under eighty or ninety days. Improved relations between central stations and contractor-dealers are doing their part in establishing better conditions. Railroads, central stations and large industrial plants are meeting their obligations well and considerable discounting of bills is being practiced by larger buyers. Overcompetition has tended to reduce somewhat the number of organizations undertaking to do electrical supply jobbing in this territory. While the cost of doing business is still very high, increasing volume of trade is a powerful factor in creating favorable sentiment toward the year's prospects, and there is nothing in sight to justify disquiet as to collections in the next few weeks.

## The Metal Market

### Copper Continues Strong at 15 Cents—A Few Others Selling at 15.12½ Cents

The copper market continues strong, most holders quoting 15 cents a pound. A few other big selling agents are firmly quoting 15.12½ cents and show no inclination of reducing their price to 15 cents to attract some of the going business. These latter sellers are steadfast in their opinion that the market is due to go higher, especially if the present demand from the consumers continues. Export business in copper is slightly better, although orders are not large. Quotations are unchanged at 14.75 to 14.80 cents, f.o.b. New York harbor, and 14.95 to 15 cents, c.i.f., European ports.

NEW YORK METAL MARKET PRICES

| | Jan. 31, 1923 Cents per Pound | Feb. 6, 1923 Cents per Pound |
|---|---|---|
| Copper | | |
| Electrolytic | 14.87½–15.00 | 15.00–15.12½ |
| Lead, Am. S. & R. price | 7.75 | 8.00 |
| Antimony | 7.00 | 7.50 |
| Nickel, ingot | 30.00 | 25.00–30.00 |
| Zinc, spot | 7.00 | 7.05 |
| Tin Straits | 38.62½ | 39.00 |
| Aluminum, 98 to 99 per cent | 23.00 | 22.00–23.00 |

## Copper and Brass Products

Copper, brass and bronze mills quote the following prices on brass and copper products:

Copper wire, 16.38 to 16.63 cents net, mill; brass wire, 19.5 to 21.5 cents; copper sheets, 22.25 cents; copper rods, 15.5 to 15.75 cents; brass rods, 17.25 to 21.38 cents; sheet brass, 19 to 20.63 cents.

# The Week in Trade

**Prices When Quoted Are Those Reported at the Opening of Business on Monday of This Week for Points West of the Mississippi River and on Tuesday for All Eastern Points**

PRICES of wire, conduit and flexible cable are slightly stronger owing to the continued heavy demand by the building industry and to longer deliveries. A noticeable spurt in sales of high-tension equipment and poles to central stations that are making extensions and repairs is reported in the Far West and Middle West. Some labor trouble in the textile field and telephone unions is causing concern. Electrical interests are well satisfied with the building outlook for the spring and summer months. Motor manufacturers report increasing business and fair stocks. One maker of a quality vacuum cleaner reports that his sales are 25 per cent heavier than they were six months ago, 15 per cent of this increase being laid to improved business conditions and the remaining 10 per cent to greater sales effort. Keen competition in metal reflector fixtures along the Pacific Coast has resulted in a 10 per cent price drop. Retail trade has been hampered somewhat by the colder weather, although the volume of heater sales is disappointing. Stocks of complete radio sets are reported spotty.

**New York** Demand for all appliances is only fair, a lull which is expected to be of short duration. Supplies and equipment to central stations show some improvement. Jobbers and contractors expect the coming year's construction of industrial and residential buildings to bring record-breaking orders. Fixtures are on a keen merchandising basis, with firm prices. Motors are showing improvement and stocks are only normal. Radio shows added strength with stocks of the better sets in a decreased state.

**Chicago** Basic commodities, including wire, conduit and flexible cable, are selling well. Shipments of conduit are improving, but the present demand is too great to allow much stocking up on this material. Jobbers report a fair trade in fuses, schedule material and fixtures, since most of the building construction will not be finished until April. Motor manufacturers declare that January was a continuation of December's sales rate.

**Boston** Retail trade has been hampered somewhat by cold weather. Manufacturers are well supplied with orders for many weeks ahead in most lines. Radio stocks are spotty in the face of a heavy demand for apparatus, greatly stimulated by improved broadcasting programs. Labor conditions are disturbed in the textile field, with internal difficulties evident in the telephone unions. The outlook is good for an active spring in the building industry, with price conditions in control of commitments for summer and fall.

**Baltimore** Business is proceeding at a normal rate with an upward trend shown in the prices of cable and wire. Most of the jobbers are well stocked. Although prices are remaining firm on heaters, the demand is beginning to show a seasonal decline. Motors, although showing a steady demand, are declining considerably in price. Business during the month of January was reported as very good from practically all the dealers and jobbers, and the outlook is good.

**Atlanta** Shipments on heavy electrical apparatus are lengthening. Jobbers report business as a whole very good with a pick-up in the demand for pole-line hardware as a result of the sleet storm of ten days ago. The volume of heater sales is disappointing. Telephone interests in this district have announced a program of expansion which will call for the expenditure of $1,500,000 during the coming year.

**Cleveland** Trade generally continues brisk and the volume has been distributed over many commodities. Collections are improving. Manufacturers are increasing production in anticipation of heavy buying in the spring. Despite the colder weather, building operations continue to maintain a strong demand for fixtures and lamps. Appliance sales are fair. Heaters are improving.

**Pittsburgh** Increasing business in the jobbing field is reported. Prices generally are firm, and stocks are quite well maintained. Rubber-covered, bare and weatherproof wire have shown a slight advance with a steady demand. Central-station business is more active than during the month of January. Collections generally are improving. Orders for central-station equipment are larger.

**St. Louis** Jobbing business continues to improve. The holiday demand had a stimulating effect upon the distribution of radio sets, household appliances and fancy lamps. The almost uninterrupted building operations due to the open winter have been reflected in orders for wiring, which are reported as unusually heavy for this season of the year.

**New Orleans** A slight increase in business is noticeable, dealers and jobbers reporting good sales in appliances and lamps. Central-station equipment is moving in larger volume. Collections are somewhat improved. Building construction continues at a fair rate.

# Demand, Supply and Price Trend of Eighteen Commodities as Sold in Sixteen Cities

Explanation:
Demand: Steady, Slow or Active
Supply: Normal, Low or High
Price Trend: Firm, Decreasing or Increasing

Next Week Reports will include Washers and Cleaners, Conduit Boxes and Tape

## St. Paul-Minneapolis

Business is excellent with retail buying above normal. Construction of buildings continues at a fair rate helped by open winter weather. Dealers are showing their confidence in the general situation by ordering in large amounts. Demand for complete radio sets and parts is increasing. Radio stocks are low and there is a shortage of quality material. A big demand for rectifiers continues with very low stocks.

## Salt Lake City

The market is steady with no important changes from prices of last week. Jobbers and dealers generally have settled down to hard sales work, adhering strictly to budget limits and keeping to conservative lines. Washer campaigns will be on with the arrival of March, and the tendency will be to limit advertising expenditures. A shortage of skilled labor is expected as construction increases.

## Denver

Sudden cold weather has retarded building construction for the first time. Building permits are increasing, the total for the year thus far having passed $1,500,000, and this represents a 30 per cent increase over the corresponding period of last year. Railroads and industrial plants are making extensive inquiries relative to electrical installations, and a number of central stations in this district are planning improvements.

## San Francisco

Sales continue at a fair rate. Several jobbers are engaged in fixture-sales campaigns and are helped by extensive advertising. There is keen competition along the entire coast in the metal reflector market, which has resulted in a 10 per cent price drop and slower deliveries from the factories. Radio stocks are rather spotty and demand continues fair. Prices are firm.

## Portland-Seattle

Business reports indicate very little change, sales remaining good for this time of the year. There seems to be no indication of a slackening in the demand for materials entering into new construction. Electrical permits in building show an appreciable increase over December, 1922, the valuation for Portland being 30 per cent greater. All the larger power companies in the Northwest are working on developments of considerable magnitude.

# Activities of the Trade

Devoted to News of the
Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

## Wagner Electric Elects Officers

At a meeting of the board of directors of the Wagner Electric Corporation held Jan. 25 the following officers were elected: W. A. Layman, president; A. H. Timmerman, vice-president; P. B. Postlethwaite, vice-president; T. T. Richards, vice-president; V. W. Bergenthal, treasurer, and J. W. Wescott, secretary. According to officials of the corporation, miscellaneous general sales for the months of December and January increased more than 100 per cent over those of one year ago, and January plant production will be 100 per cent greater than for the same month last year.

## Electric Truck Sales Conference

The Cowan Truck Company, Holyoke, Mass., held a three-day sales conference from Jan. 27 to 29, the sessions being at the company's plant in Holyoke and at a local hotel. A complete tour of inspection of the works was made and a new model electric truck was demonstrated. On Jan. 28 Col. Charles R. Gow, Boston, president of the Associated Industries of Massachusetts, addressed the officers and salesmen on "The Advantages and Disadvantages of Doing Business in New England."

## Uehling Instrument Order

The Solvay Process Company, which installed 24 Uehling $CO_2$ recording and indicating units in its Syracuse (N. Y.) plant last October, has just ordered eight additional similar units from the Uehling Instrument Company, Paterson, N. J., for its boiler plant at the same works. This company also has numerous Uehling $CO_2$ recorders at its Detroit (Mich.) and Hutchinson (Kan.) plants.

## Electric Sign Company Institutes Suit for Patent Infringement

A suit for infringement of patent has been instituted in the Supreme Court, New York County, by the Electric Sign Company, 240 West Twenty-fifth Street, against the Norden Electric Sign Company, American Sign Company, P. J. Martin, Inc., Atlas Electric Sign Corporation and Straus & Company, Inc., to procure an injunction restraining these companies from manufacturing electric display signs which, it is claimed, infringe upon the patents under which the Electric Sign Company is manufacturing. The patent rights involved in this suit cover a new type of electric sign, invented by Bruno von Bueltzingsloewen, for which an extremely low current consumption is claimed. The von Bueltzingsloewen patents are the property of the Electric Sign Company, which is bringing suit not only for patent infringement by the defendant companies but also for an accounting on signs already constructed by the defendants, which, it is alleged, violate the rights in question.

## General Electric Workers Will Receive Stock in April

Approximately ten thousand General Electric Company employees who have been paying for the common stock of the company on the installment plan for the last two years will make final payments in March and will receive their stock probably about the first part of April. Weekly deductions, which have been made at the rate of $1 per share, will terminate March 16. First dividends on this new issue will be paid July 15. The authorization of this stock issue was for 50,000 shares with a par value of $5,000,000.

## Crocker-Wheeler Enters Radio Field with New Line

The Crocker-Wheeler Company, which did a great deal of manufacturing of radio sending apparatus for the navy previous to and during the war, particularly in the line of generators and dynamotors, has now, since the development of the audion, turned its attention to receiving devices. Dr. S. S. Wheeler, the president of the company, has authorized the ELECTRICAL WORLD to announce that the company is now ready to place on the market the "Add-a-Unit" line of radio apparatus, which will consist of high-quality independent units arranged with binding posts. The various units will consist of detector tube or radio frequency amplifier or audion frequency amplifier or variometer, etc., each unit to be in a well-finished case. These units can be combined into "sets" or combinations from simple to most complex. The idea is to market them on an individual-unit basis under quantity production at a reasonable unit cost.

## White-Cedar-Pole Men Meet in Minneapolis

The twenty-seventh annual meeting of the Northern White Cedar Association was held at the West Hotel, Minneapolis, on Jan. 30-31. There was a large attendance from all the cedar-pole producing and selling organizations which make up its membership.

Co-operation with the pole buyers in producing and manufacturing a better quality of white cedar pole was shown. The Northern White Cedar Association specifications were thoroughly discussed, and changes were made in inspection rules to insure the kind of poles needed for hard usage on central-station lines. To show more clearly the buyer of white-cedar poles and the public utilities just what conditions go to make up the production of "quality" poles a constructive publicity and advertising campaign was authorized.

## Bussmann Company Opens New Office in Philadelphia

The Bussmann Manufacturing Company, manufacturer of fuses, St. Louis, has opened an office in the Philadelphia Bourse, Philadelphia, with A. E. Arthurs, district manager, in charge. Mr. Arthurs has been with the Bussmann company for a number of years, the greater part of time as district manager of the Pittsburgh territory. R. C. McDaniels succeeds him in Pittsburgh.

## Takes Maine Pneuvac Agency

C. M. Quick, formerly Portland (Me.) manager of the Gainaday Electric Company, has been appointed agent for Maine for the Pneuvac Company, Worcester, Mass., with a new office under the name of the C. M. Quick Electric Company, 548½ Congress Street, Portland.

**The Electrical Appliance Manufacturing Company**, Waterbury, Conn., has purchased land and buildings at 987 Watertown Avenue, Waterbury, and is altering the buildings for its own occupancy.

**The Litcher Electric Company**, 41 Market Avenue, Grand Rapids, Mich., manufacturer of electrical equipment, is completing plans for three-story and basement works, to replace its plant recently destroyed by fire.

## Westinghouse Awards Contract for $200,000 California Plant

The Westinghouse Electric & Manufacturing Company has awarded a contract for the erection of the first unit of its proposed plant at Emeryville, Cal., where a site of 12 acres has been acquired. The structure will be one and two-story and is estimated to cost close to $200,000. Other units of approximately the same size and cost will be built later. The present plant will be operated by the Westinghouse High Voltage Insulator Company, a subsidiary organization, with headquarters at Derry, Pa., and will be devoted exclusively to the manufacture of high-tension insulators, utilizing local clays for raw material. The main building will consist of four oil-burning kilns, to be extended later to twelve such kilns. The initial working force will approximate one hundred operatives. Ray P. Hunt, manager of the material and process department at the East Pittsburgh works of the parent organization, has been appointed manager of the new Emeryville plant.

## Foreign Trade Notes

NEW ELECTRIC PROJECT IN CZECHO-SLOVAKIA.—A company has been organized with the assistance of the State and the Province of Bohemia which will supply electricity in Prague. The company is capitalized at 180,000,000 crowns and will be known as the Central Electricity Works, with headquarters at Ervenice. The proposed plant, work on which has already started, will be erected near the Edwige lignite field at Ervenice. The initial installation will have a capacity of 45,000 kw. Electricity will be transmitted to Prague at 100,000 volts.

NEWCASTLE, AUSTRALIA, TRAMWAY SYSTEM TO BE ELECTRIFIED.—The state government of New South Wales, Australia, *Commerce Reports* states, has decided to equip the tramway system of the city of Newcastle for electrical operation. The system will cover about 50 miles of tracks in Newcastle and suburbs and will cost about $5,000,000. Power will be furnished by the present 25-cycle electric power plant (a state property) situated within the city limits.

## Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number.

An agency is desired in the Fiji Islands (No. 5,253) for electrical supplies, general hardware, etc.

Purchase and agency is desired in England (No. 5,255) for instantaneous automatic water heaters.

Purchase is desired in Spain (No. 5,276) for a machine for the reconditioning of worn and flattened electric car wheels.

An exclusive agency is desired in Canada (No. 5,290) for electrical devices or appliances.

An agency is desired in Switzerland (No. 5,314) for new inventions in machinery and electrical novelties.

EQUIPMENT FOR PORT ELIZABETH (SOUTH AFRICA) ELECTRIC PLANT.—Tenders will be received by the Municipal Council, Port Elizabeth, South Africa, until April 16 for a 3,000-kw. turbo-alternator, boilers, coal hoppers, coal conveyors, boiler house, steam and feed-water pipes, etc.

METERS, CABLES AND ACCESSORIES FOR ELECTRIC WORKS, MONTEVIDEO, URUGUAY.—Tenders will be received by the State Electricity Works, Montevideo, Uruguay, until March 15 for 1,500 direct-current and 8,500 alternating-current meters, etc. Tenders will also be received until March 10 for 66,000 m. (about 72,600 yd.) of high-tension cable and accessories.

ELECTRIC GENERATOR AND BOILER FOR JOHANNESBURG PLANT, SOUTH AFRICA.—The Municipal Council of Johannesburg, it is stated, has decided to ask for tenders for equipment for the municipal electric plant, including an 8,000-kw. generating unit, with switchgear, cables, etc., and one 45,000-hp. boiler.

APPROPRIATION FOR EXTENSIONS TO THE VICTORIA, AUSTRALIA, ELECTRICITY SCHEME.—A bill has been adopted by the Victorian House of Assembly providing for an appropriation of £1,576,000 for projects of the State Electricity Commission as follows: For additions to the main works, including power house, etc., at Yallourn (Morwell), to cost £760,000; extensions to the transmission line to the southwest of the state £120,000, for the Sugarloaf hydro-electric project, £50,000, and for an electric scheme in Gippsland, beyond Morwell, £70,000.

## New Apparatus and Publications

ARC WELDING.—The Burke Electric Company, Erie, Pa., is distributing bulletin No. 127, covering its electric arc welding equipment.

METALS AND ALLOYS.—Henry Carey Baird & Company, Inc., 2 West Forty-fifth Street, New York City, will soon bring out a new book on alloys, entitled "Metals and Their Alloys," by Charles Vickers.

BALL AND ROLLER BEARINGS.—Pamphlet No. 13 issued by the Hoffman Manufacturing Company, Ltd., Chelmsford, Essex, England, describes the use of "Hoffman" ball and roller bearings on electrical machinery. The Norma Company of America, Anable Avenue, Long Island City, N. Y., is agent for the company in the United States.

LIGHTING DATA.—The Edison Lamp Works of General Electric Company, Harrison, N. J., is distributing bulletins L.D. 110A, L.D. 140, L.D. 141, L.D. 142, L.D. 143 and L.D. 144, entitled "The Lighting of Textile Mills," "The Lighting of Paper and Pulp Mills," "Automobile, Garage and Display Room Lighting," "The Lighting of Woodworking Plants," "Lighting of the Food Industries" and "Street Lighting with Mazda Lamps" respectively.

PULVERIZING MILL.—"Hardinge Conical Mills" is the title of catalog No. 13, section 1, issued by the Hardinge Company, 120 Broadway, New York City, which describes its conical ball and pebble mills and their application to the field of grinding and pulverizing.

TURBOBLOWER.—The B. F. Sturtevant Company, Hyde Park, Boston, is distributing a leaflet describing the "Sturtevant turboblower" installed in the Fall River (Mass.) Gas Works.

BOILER FURNACE ECONOMIES.—Bulletin No. 53 issued by the Quigley Furnace Specialties Company, 26 Cortland Street, New York City, describes and illustrates a method of reconstructing and patching boiler-furnace walls with "Hytempite."

CUPOLA TAPPER AND STOPPER.—The Medart Company, Potomac and De Kalb Streets, St. Louis, is distributing a leaflet covering the "Medart" safety cupola tapper and stopper, recently developed by the company.

OXY-ACETYLENE WELDING AND CUTTING.—The Norman W. Henley Publishing Company, 2 West Forty-fifth Street, New York City, has published the revised and enlarged sixth edition of "Oxy-Acetylene Welding and Cutting," by P. F. Willis.

COAL-HANDLING MACHINERY.—"How Hell Gate Station Handles Coal with Maine Electric Machinery" is the title of bulletin No. 4, issued by the Maine Electric Company, Portland, Me., which describes and illustrates the coal-handling equipment installed in the Hell Gate plant of the United Electric Light & Power Company.

GLOSSARY OF ELECTRICAL TERMS.—The Bureau of Foreign and Domestic Commerce announces a new edition of the "Glossary of Electrical Terms," which has been compiled by the Electrical Equipment Division in co-operation with the Electrical Manufacturers' Council. It has been prepared to conform to changes in the export classification schedule which went into effect on Jan. 8, 1923. This pamphlet is intended solely for reference purposes by exporters when making out their export declarations, so that these will indicate accurately the goods shipped in so far as statistical classifications are concerned.

## New Incorporations

THE EAST RAINELLE LIGHT & POWER COMPANY, Rainelle, W. Va., has been incorporated with a capital stock of $25,000 by D. D. Raine, J. W. Gray and J. G. Shewey.

THE KINZUA (PA.) POWER & LIGHT COMPANY has been chartered with a capital stock of $5,000 by Fred H. Smith, H. R. French, Kinzua, and C. C. Flatt, Corydon. The company proposes to supply electricity for lamps, heaters and motors.

THE LAMAR (IND.) LIGHTING COMPANY has been incorporated with a capital stock of $2,500 to supply electricity for lighting purposes. The directors are B. W. Huebschman, Claude R. Martin and Fred P. Keller.

THE BOCARATONE (FLA.) WATER & LIGHT COMPANY has been chartered with a capital stock of $25,000 to generate and distribute electricity, operate water works, gas systems, etc. The officers are: J. McL. Stevens, president; G. H. Howard, vice-president, and W. L. Brown, secretary and treasurer.

THE SMITH RIVER (CAL.) LIGHT & POWER COMPANY has been organized for the purpose of supplying electricity in Smith River. The officers are: C. Romander, president and general manager; Henry Westbrook, Sr., vice-president, and George D. Wood, secretary and treasurer.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

BOSTON, MASS.—The Edison Electric Illuminating Company of Boston has acquired a site at Warrenton and Carver Streets on which it proposes to erect a large substation, from which electricity generated at the station on Summer Street and later from the new Weymouth station, will be distributed in this territory.

LOWELL, MASS.—The chief of the Fire Department has recommended the installation of a new fire-alarm system. The cost is estimated at about $200,000.

TAUNTON, MASS.—The installation of an ornamental lighting system in tho business district is under consideration.

WAKEFIELD, MASS.—The local works of the Heywood-Wakefield Company will be equipped throughout for electrical operation. The company has contracted with the commissioners of the municipal electric plant for electricity to operate its plant.

CRANSTON, R. I.—Negotiations are under way between Mayor Arthur Rhodes and the Narragansett Electric Lighting Company for improvements to the street-lighting system.

NORWALK, CONN.—Plans for the proposed hat factory to be erected on Van Zandt Street by the Crofut & Knapp Company, South Norwalk, include a power plant. The cost is estimated at $750,000.

WATERBURY, CONN.—The Connecticut Light & Power Company has issued $4,500,000 in capital stock, part of the proceeds to be used in connection with its 100,000-hp. generating plant at Devon. Later three additional units will be installed to double the capacity of the plant.

## Middle Atlantic States

HAMMOND, N. Y.—The Rossie (N. Y.) Electric & Manufacturing Company contemplates extensive improvements to its local plant, including the installation of new generating equipment and the erection of 94 miles of transmission lines.

MEDINA, N. Y.—The Genesee Light & Power Company, Batavia, has acquired the Western New York Utilities Company. Extensions will be made in the transmission system and operations continued under the present name.

NEW YORK, N. Y.—The New York Central Railroad Company is planning to establish a 2,000-kw. substation at Park Avenue and 110th Street for third-rail train service.

NEW YORK, N. Y.—Bids will be received by the Board of Purchase of the City of New York, Room 526, Municipal Building, until Feb. 14 for furnishing weatherproof cable to the Department of Plant and Structures.

NEW YORK, N. Y.—Bids will be received by the Department of Public Welfare, Tenth Floor, Municipal Building, until Feb. 13 for furnishing and installing new partitions, electric wiring and heating on the first and second floors of pavilions 7, 8, 9 and 17, Sea View Hospital, borough of Richmond, city of New York.

SHERMAN ISLAND, N. Y.—The International Paper Company, 30 Broad Street, New York, is planning to build a 25,000-kw. hydro-electric generating plant here.

BLOOMSBURY, N. J.—The New Jersey Power & Light Company, Dover, contemplates extending its service to Bloomsbury and to install a street-lighting system.

PHILLIPSBURG, N. J.—The Board of County Freeholders plans to establish a lighting district in Greenwich Township. Lamps will be installed on all highways.

AVONDALE, PA.—The George F. Lee Coal Company contemplates rebuilding its electrically operated coal breaker recently destroyed by fire, causing a loss of about $250,000.

EGYPT, PA.—The Pennsylvania Power & Light Company will build a transmission line from Laurys to Egypt for power service at local cement mills.

LANCASTER, PA.—Arrangements are being made by the Edison Electric Company to place its wires underground in the business section of the city. The cost is estimated at about $161,000.

PHILADELPHIA, PA.—Among the new buildings to be erected at the University of Pennsylvania is a new central power plant, which will be located on the Schuylkill River front near the South Street Bridge.

PITTSBURGH, PA. — The West Penn Power Company has secured permission to erect transmission lines in portions of Allegheny and Washington Counties.

PITTSBURGH, PA. — Electric power equipment will be installed in the baking plant to be erected by the Ward Baking Company at West Park and Ridge Avenues, to cost about $1,000,000.

RAYSTOWN, PA. — The Penn Central Light & Power Company, Altoona, has been granted permission to acquire the property of the Raystown Light & Power Company. Extensions will be made to the system.

RIDGWAY, PA.—The American Water Works & Electric Company, 50 Broad Street, New York, has acquired the Keystone Power Corporation, operating at Kane, Smethport and vicinity. Extensions and improvements will be made in the system.

SUMMERVILLE, PA. — Arrangements have been made with the Jefferson Electric Company, Punxsutawney, to extend its lines to Summerville. Power will be furnished by the West Penn Electric Company.

BALTIMORE, MD. — The Consolidated Gas, Electric Light & Power Company plans to build an electric switching and operating department on Kloman Street, to cost about $105,000.

MONONGAH, W. VA. (P. O. Fairmont) —The Monongah Fuel Company will install a substation, switchboard room and other electrical departments for mine service.

APPOMATTOX, VA.—Residents of the town have organized a company to establish an electric light plant to replace the one destroyed by fire recently. The sum of $25,000 has been subscribed to the stock of the company.

RADFORD, VA.—The City Council is considering the installation of an ornamental lighting system.

WASHINGTON, D. C.—Plans are being prepared by the Commissioners of the District of Columbia for alterations and additions to the Armstrong Manual Training School, to cost about $500,000.

WASHINGTON, D. C.—Bids will be received by Louis A. Hill, director of the Bureau of Engraving and Printing, Washington, D. C., until Feb. 17 for fifty-eight motor equipments for power plate-printing presses.

WASHINGTON, D. C.—Bids will be received by the Purchasing Agent Post Office Department, until Feb. 14 for 500 three-cell cylindrical flashlight batteries.

## North Central States

PONTIAC, MICH. — The Fisher Body Corporation, Detroit, will build a power house in connection with its proposed local plant, to cost about $2,000,000.

AGOSTA, OHIO.—The installation of a local light and power system for commercial service is under consideration.

CLEVELAND, OHIO.—Bids will be received at the office of the commissioner of purchases and supplies, City Hall, until Feb. 16 for furnishing turbo-generators, air compressor, vacuum pumps and vacuum cleaning equipment for the Fairmont pumping station, division of water, Department of Public Utilities.

FRANKFORT, OHIO.—Plans are under consideration by the City Council to secure electricity to operate the local system. It is proposed to extend the line from New Holland.

LOWELLVILLE, OHIO.—The Pennsylvania-Ohio Power & Light Company, Youngstown, plans to build an addition to its local plant to increase the output by 15,000 kw.

BROWNSVILLE, KY.—The Rock Asphalt Company, Bowling Green, plans to build a power house in connection with a new plant on the Green River, to cost about $200,000.

LOUISVILLE, KY.—The construction of a joint interurban station at Second and Liberty Streets, to cost about $500,000, is under consideration by the Louisville Railway Company.

MADISONVILLE, KY.—The Kentucky Utilities Company, Louisville, has contracted to furnish electricity here. The municipal power plant will be closed down.

INDIANAPOLIS, IND.—The Indianapolis Light & Heat Company will install a transmission line on Belmont Avenue and other thoroughfares.

CARLYLE, ILL.—Bids will be received at the office of the city clerk, until Feb. 19 for construction of a filtration plant, including two centrifugal pumps with motors, transformer, valves, connections, etc. Dawson & Walraven, Springfield, are engineers.

CHARLESTON, ILL.—The Central Illinois Public Service Company contemplates the construction of a one-story ice-manufacturing and cold-storage plant, 75 ft. x 75 ft., in Charleston. L. D. Roberts, 130 North Sixth Street, Springfield, is engineer for the company.

CHICAGO, ILL.—Plans are being prepared by D. I. Davis and associates, 327 South La Salle Street, for a power plant, to cost about $60,000.

CHICAGO, ILL.—The Woodlawn Business Men's Association has petitioned the City Council for the installation of new street lamps on Sixty-third Street from Jackson Park to South Park. The cost is estimated at $45,000.

CHICAGO, ILL. — An addition will be built to the power house at the Michael Reese Hospital, Twenty-ninth Street and Ellis Avenue. Schmidt, Garden & Martin, 104 South Michigan Avenue, are architects.

FREEPORT, ILL.—The Arcade Manufacturing Company has engaged C. E. Wolfley, architect, Stewart Building, to prepare plans for extensions to its power house, to cost about $35,000.

GRANITE CITY, ILL.—Extensive improvements are being made by the Madison County Light & Power Company, including the erection of a transmission line from Venice to Wool River and East Alton and the installation of new equipment in the generating stations at Edwardsville and Venice. The cost of the work is estimated at about $200,000.

KEWANEE, ILL.—Plans are being prepared for the installation of a municipal electric light plant, to cost about $125,000. Burns & McDonnell, Interstate Building, Kansas City, Mo., are engineers.

CHETEK, WIS.—The Wisconsin Hydro-Electric Company, Amery, will begin work in the spring on the reconstruction of the local system and will also erect heavier wires between Chetek and its two hydro-electric plants at Amery and Colfax.

KENDALL, WIS.—The plant of the Kendall Electric Company has been purchased by the Eastern Wisconsin Electric Company, Sheboygan, which will supply electricity for the local system from its high-tension transmission lines.

MARINETTE, WIS.—Extensive improvements are contemplated by the Menominee & Marinette Light & Traction Company, including extensions to the Rapids power plant, to cost $210,000; improvements to the electric distribution systems of the twin cities, together with the construction of a large substation on Wells Street, Marinette, and that part of the high-tension line in this city, to cost $120,000. The transmission line from Pound to the city limits, connecting the hydro-electric and steam systems, will cost more than $100,000.

MONROE, WIS.—The property of the Monroe Electric Company has been acquired by the Wisconsin Utilities Company, Martintown. The latter company has been granted permission to issue $315,000 in bonds, part of the proceeds to be used for extensions and improvements to the local system.

RACINE, WIS.—The Wisconsin Gas & Electric Company is planning to install additional electrically operated unloading machinery on the river dock property, recently purchased by the company.

SHAWANO, WIS.—The installation of an ornamental lighting system on Main Street is under consideration by the Council.

WEST ALLIS, WIS.—The City Council is considering the installation of an ornamental lighting system on Sixth-eighth Avenue Boulevard and on National Avenue from Forty-seventh to Sixty-sixth Avenue. It is also proposed to establish a brightly lighted street from the northern city limits to Greenfield Avenue.

ST. CHARLES, MINN.—The Minnesota Gold Mining Company contemplates the installation of an electric substation in connection with its proposed ore-reduction plant to cost about $125,000.

BURLINGTON, IOWA.—The Burlington Glass Company plans to build a power house in connection with its proposed local glass works on North Main Street, to cost $250,000.

CEDAR RAPIDS, IOWA.—Plans for the proposed hospital building, to be erected by the Mercy Hospital Association, Sixth and Division Streets, to cost $250,000, include a power house.

KANSAS CITY, MO. — Electric power equipment will be installed in the ice-manufacturing plant to be erected at 4730 Tracy Street by the American Ice Company, to cost about $110,000.

KIRKSVILLE, MO.—A special election will be held on Feb. 24 to vote on the proposal to issue $40,000 in bonds for a municipal electric plant.

EMPORIA, KAN.—The Atchison, Topeka & Santa Fé Railroad Company plans to build a power house in connection with its proposed local repair shops, to cost about $5,000,000.

KANSAS CITY, KAN.—Plans are under consideration for changing the entire street-lighting system from gas to electricity, and also for extensions to the ornamental street-lighting system.

## Southern States

CRAMERTON, N. C.—Plans for the proposed local textile mill to be erected by the Mays Mill, Inc., to cost about $1,000,000, include a power house. J. E. Sirrine & Company, Greenville, S. C., are engineers.

CHARLESTON, S. C. — Electric cranes, transportation equipment, etc., will be installed in connection with the proposed municipal pier to be built by the Port Utilities Commission, to cost about $1,000,000.

GRAYSVILLE, GA.—A power plant will be installed in the proposed crushed stone works to be constructed by the Chickamagua Quarry & Construction Company, with an initial capacity of 500 tons per day.

JACKSONVILLE, FLA.—The City Council is considering a bill submitted by the City Commission recommending an expenditure of $850,000, covering a period of three years, for extensions to the municipal electric plant, erection of substations and transmission lines.

MIAMI, FLA.—The Council contemplates calling an election to submit the proposal to issue $400,000 in bonds for extending the street-railway system to the suburbs. C. W. Murray is city engineer.

ST. PETERSBURG, FLA.—The Greater St. Petersburg Land Company plans to install a lighting system on an 800-acre tract now being developed for residential purposes.

GREENVILLE, TENN. — The Tennessee Eastern Electric Power Company Johnson City, will install a new unit at its local hydro-electric station.

COLUMBUS, MISS.—Bids will be received by the State Bond Improvement Commission, Jackson, until Feb. 24, for the construction of a central power house at the Mississippi State College for Women. The cost is estimated at about $70,000.

GULFPORT, MISS.—Bids will be received by the Bureau of Yards and Docks, Navy Department, Washington, D. C., until Feb. 21 for an ice-manufacturing and refrigerating plant at the United States Veterans' Hospital, Gulfport, specification 4,780. The equipment will include motor-driven compressors, condensers, etc.

QUANAH, TEX.—The Quanah Light & Ice Company will install additional equipment at its power plant.

SLATON, TEX. — The Texas Utilities Company will make extensions and improvements to the system of the Slaton Light & Power Company, recently acquired.

STAMFORD, TEX. — The Chicakasha (Okla.) Cotton Oil Company contemplates the erection of a new local plant, to cost about $150,000. The tentative plans include a power house.

## Pacific and Mountain States

ALBANY, ORE.—Extensions and improvements are contemplated by the Mountain States Power Company in the Willamette Valley, including the erection of a transmission line from Prospect to Springfield, to cost about $200,000.

BAKER, ORE. — The Eastern Oregon Light & Power Company is reported to be considering the erection of a steam generating plant, to cost about $200,000, or the purchase of the equipment and business of a power company operating in this vicinity.

HUNTINGTON, ORE. — The Columbia Cement Company, Concord Building, Port-

land, will build a power plant in connection with its proposed local cement manufacturing plant, to cost about $1,000,000.

NEWPORT, ORE.—The property of the Yaquina Electric Company has been taken over by the Lincoln County Light & Power Company, Toledo, recently organized. The local system will be reconstructed and a twenty-four-hour service established. A new substation will also be built.

LOS ANGELES, CAL. — Construction plans which will develop 1,250,000 hp. of electrical energy to serve ten counties in southern California have been announced by the Southern California Edison Company. The work will include as the first step in the large project the erection of a terminal station, to cost $2,000,000, which will be known as the Laguna Bell substation and have a capacity of 165,000 hp. Energy for the new station will be supplied from the Big Creek transmission lines.

LOS ANGELES, CAL. — The County Supervisors contemplate the installation of a lighting system in the Willowbrook section.

LOS ANGELES, CAL. — The Southern California Edison Company plans to erect a transmission line over Anaheim Bay, Seal Beach district.

LOS ANGELES, CAL.—An ordinance has been passed authorizing the installation of an ornamental lighting system on Sunset Boulevard from Stanley Avenue to Vista Street.

PASADENA, CAL.—Extensions are contemplated to the municipal electric plant, including the erection of a step-up substation, cooling towers, etc. The installation of four additional boilers in the generating plant is also planned. The cost of the improvements is estimated at about $300 000.

RIVERSIDE, CAL.—Electric power equipment will be installed in the proposed ice-manufacturing and refrigerating plant, 100 ft. x 100 ft., to be built by the National Ice & Cold Storage Company, Twelfth Street.

SAN FRANCISCO, CAL.—Bids will be received by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., until Feb. 27 for 4,200 ft. of electric wire (Schedule 465) and for 7,500 ft. of radio frequency cable (Schedule 480) for the Mare Island Navy Yard.

SAN JOSE, CAL.—The Pacific Gas & Electric Company will make extensions and improvements to its local plant, including the installation of additional equipment, to cost about $100,000.

SMITH RIVER, CAL.—The Smith River Light & Power Company, recently organized, is building an electric plant. Orders, it is stated, have been placed for a generator and two Diesel engines. C. Romander is president and general manager.

WILLITS, CAL. — The State Railroad Commission has granted the Central Mendocino County Power Company permission to purchase the water and electrical distributing system of the Willits Water & Power Company, together with 5,260 acres of watershed lands.

GERLACH, NEV.—Plans have been prepared by Weeks & Day, California Insurance Building, San Francisco, for a town site for the Pacific Portland Cement Company, Pacific Building, San Francisco, to include hotel, cottages, power plant, tramways, etc.

## Canada

VANCOUVER, B. C.—The Bridge River Power Company contemplates the construction of a hydro-electric plant near Seton Lake, Lillooet, to develop about 400 000 hp. Electricity generated at the proposed plant will be used to augment the power plants of the Vancouver Power Company at Coquitlam and Stave Lake and will be transmitted to and distributed in Vancouver.

MEAFORD, ONT. — A bylaw has been passed by the Town Council authorizing an agreement with the Hydro-Electric Power Commission of Ontario for the erection of transmission line, to cost about $65,000.

PORT ARTHUR, ONT.—The construction of a third unit at the Nipigon hydro-electric plant, to provide an additional 12,000 hp., is under consideration by the Hydro-Electric Power Commission of Ontario.

TORONTO, ONT.—The Temiskaming & Northern Ontario Railway Company has authorized plans prepared for the electrification of its lines, including the road from North Bay to Cochrane, 250 miles; the Iroquois subdivision, 7 miles, and the Porcupine division, 33 miles, to cost about $10 000,000, with equipment.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued Jan. 16, 1923)

1,442,474. RECORDING TELEGRAPHIC RECEIVING INSTRUMENT; J. A. Hulit, Chicago, Ill. App. filed Dec. 13, 1920. Adjustment of pen recorders used on tapes.

1,442,487. LOCKING MECHANISM FOR MOTOR VEHICLES; O. A. Lucier, Baltic, Conn. App. filed May 6, 1921. Ignition circuit lock.

1,442,496. ELECTRICAL CONTROLLER; E. W. Seeger, Milwaukee, Wis. App. filed April 13, 1922. Fluid rheostats for induction-motor control.

1,422,508. BURGLAR AND LIKE ALARM SYSTEM; S. G. Adams, Lewisham, England. App. filed May 1, 1922. Combined with telephone system with visual indicator in exchange.

1,442,514. ELECTROPLATING MACHINE; F. J. Bell, Cleveland, Ohio. App. filed April 22, 1922. Adapted for galvanizing wheel rims.

1,442,545. MAGNETIC CHUCK; O. S. Walker, Worcester, Mass. App. filed March 28, 1919. Number of pole pieces in form of parallel, oppositely magnetized strips.

1,442,608. VARIABLE-FIELD DEHYDRATOR; H. C. Eddy, Los Angeles, Cal. App. filed June 25, 1921. Length of electric field automatically increased when current increases.

1,442,648. CORD CONDUCTOR; C. E. Carter, Montreal, Can. App. filed Oct. 23, 1920. Cord connected to exterior resistances for motion-picture machines.

1,442,728. CONTROLLING AND REGULATING APPARATUS; F. W. Meyer, Milwaukee, Wis. App. filed Jan. 13, 1917. Eliminating hunting action in converters by use of electroionic valves.

1,442,770. AUTOMATIC TELEPHONE AND SELECTIVE SIGNALING SYSTEM; T. G. Martin, Chicago, Ill. App. filed Nov. 30, 1907. Relates to systems in which selective ringing on party lines is necessary.

1,442,773. HOMOGENEOUS CRYSTALLINE PRODUCT AND METHOD OF MAKING THE SAME; H. A. Richmond and R. MacDonald, Jr., Niagara Falls, N. Y. App. filed April 25, 1922. Uses electric arc furnace.

1,442,781. REAMPLIFYING SYSTEM; H. W. Nichols, Maplewood, N. J. App. filed July 7, 1921. One element of the feed-back circuit of amplifier serves as radio-receiving antenna.

1,442,791. AUTOMOBILE STARTER AND GENERATOR; W. L. Bliss, Niagara Falls, N. Y. App. filed May 27, 1915. Single-unit system.

(Issued Jan. 23, 1923)

1,442,834. APPARATUS FOR WELDING RAILS; G. N. Steigerwald, Hatboro, Pa. App. filed Dec. 16, 1921. Welding rail joints by carbon arc process.

1,442,851. EAR FOR TROLLEY WIRES; G. W. Bower, Schenectady, N. Y. App. filed May 27, 1921. Clamping ear for mine service.

1,442,854. ELECTRIC GENERATOR; J. Burke, Erie, Pa. App. filed Nov. 6, 1919. Constant-current generator for welding apparatus.

1,442,858. ADJUSTABLE TEMPERATURE BATH FOR VISCOSIMETERS; W. Claypoole, Forest Hills, N. Y. App. filed Oct. 27, 1919. Thermo-electric relay controls current.

1,442 868. GAS-TESTING MACHINE; T. R. Ernest, Chicago, Ill. App. filed March 3, 1921. Spark test chamber to determine if gas is explosive.

1,442,896. WATCH STAND AND NIGHT LAMP; J. H. Maier, Brooklyn, N. Y. App. filed Nov. 12, 1921. Bulb on stand to illuminate watch dial.

1,442,898. ELECTROMAGNETICALLY CONTROLLED BRAKE; M. E. Neenan and J. J. Neenan, New York, N. Y. App. filed July 23, 1918. For control of elevator apparatus.

1,442,903. SPOTLIGHT; A. P. Paine, New Haven Conn. App. filed Oct. 28, 1921. Variable-focus flashlight.

1,442,908. TRANSMISSION MECHANISM; W. H. Ripley, Orange, N. J. App. filed Nov. 27, 1916. Gasoline engine, generator and motor for automobile drive.

1,442,910. ELECTRICALLY HEATED VESSEL; A. Steinhardt, Berlin, Germany. App. filed Aug. 29, 1921. Element placed in ceramic material in bottom of container.

1,442,925. ELECTRIC FURNACE; D. De Luca, Cotrone, Italy. App. filed Oct. 13, 1919. Furnace for melting scrap material.

1,442,974. DISTRIBUTOR STAND; T. L. Ryan, Muncie, Ind. App. filed Sept. 8, 1921. Method of making base of table lamps.

1,442,977. ETCHING MACHINE; E. G. Schwuchow and G. F. Johnstone, Chicago, Ill. App. filed Jan. 24, 1921. Electrolytic cell for etching flat material.

1,442,988. CONDUIT CAP FOR ELECTRIC INSTALLATION; W. H. Vibber, New London, Conn. App. filed Nov. 1, 1919. Conveniently secured to building, wall or post.

1,442,999. AUTOMATIC REEL FOR ELECTRIC DEVICES; R. B. Boyle, Kansas City, Mo. App. filed March 3, 1921. Wire between telephone and wall box held taut by automatic winding reel.

1,443,007. CONTROL OF ELECTRIC CIRCUITS; L. M. Clement and A. W. Kishpaugh, East Orange, N. J. App. filed Dec. 2, 1920. Rotating tube-filament rheostat and pressing same control current and insert ammeter in circuit respectively.

1,443,011. ATMOSPHERIC DISTURBANCE-REDUCING MEANS; H. J. J. M. de Regnauld, Toulon, France. App. filed Nov. 3, 1922. Amplitude-limiting arrangements for wireless-telegraph signals.

1,443,024. ELECTRIC FURNACE; R. M. Keeney, Denver, Col. App. filed Sept. 7, 1920. Furnace for smelting cyanide precipitates.

1,443,036. FOOT SUPPORTER AND HEATER; I. Panzam, Turin, Italy. App. filed Aug. 23, 1921. Electric heater for automobiles.

1,443,066. TRANSMISSION APPARATUS; E. Belin, Paris, France. App. filed July 31, 1913. Transmitting graphic documents over wires.

1,443,073. DYNAMO-ELECTRIC MACHINE; C. F. Gilchrist, Toledo, Ohio. App. filed June 25, 1917. Automobile generator and starting motors built from same material as far as practicable.

1,443,089. ELECTRIC HAND LAMP; D. Pepper, Philadelphia, Pa. App. filed Aug. 15, 1921. Means for changing focus, and space also provided within lamp for holding two reserve lamps.

1,443,091. METHOD FOR TRANSFORMING THE KINETIC ENERGY IN GASES INTO ELECTRICAL ENERGY AND MANNER FOR UTILIZING THE LATTER FOR CARRYING OUT GAS REACTIONS; C. Petersen, Christiania, Norway. App. filed Jan. 4, 1919.

1,443,106. USHER'S SIGNAL; J. J. Walsh, Syracuse, N. Y. App. filed Sept. 30, 1921. Flashlight to indicate number of vacant seats.

1,443,123. ELECTRIC WELDING APPARATUS; G. Giorgini, Greco Milanese, Italy. App. filed Feb. 16, 1921. Machines for welding metal rims.

1,443,165. ELECTRIC SIGNALING AND CONTROLLING APPARATUS; R. P. Brown, Philadelphia, Pa. App. filed July 20, 1918. Thermo-electric relay for controlling electric furnace temperatures.

1,443,166. FURNACE-REGULATING APPARATUS; R. P. Brown, Philadelphia, Pa. App. filed July 31, 1918. Changing furnace temperature at predetermined rate.

1,443,205. ELECTRICAL APPARATUS; J. Bijur, New York, N. Y. App. filed July 3, 1919. Control device for charging storage batteries.

1,443,209. RADIO RECEIVING SYSTEM; B. Bradbury, Schenectady, N. Y. App. filed Sept. 15, 1920. Apparatus for very sharp turning.

1,443,214. MOTOR-DRIVEN APPARATUS; J. Clayton, Coventry, England. App. filed Aug. 26, 1919. Manufacture of artificial silk similar to Topham system.

1,443,251. AUTO SAFETY SIGNALING DEVICE; J. W. Elardo, Fredonia, N. Y. App. filed July 15, 1921. Rear direction signal.

1,443,254. FIRE-ALARM HYDRANT; E. E. Ferguson, Portsmouth, Va. App. filed Jan. 6, 1921. Apparatus for simultaneously turning in alarm and opening water valve, the valve being provided with hose.

1,443,321. ELECTRIC ACCUMULATOR OR STORAGE BATTERY; H. Leitner, London, England. App. filed June 23, 1922. Each element comprises one or more pencils of active material separated by porous material.

1,443,322. ELECTRIC ACCUMULATOR OR STORAGE BATTERY; H. Leitner, London, England. App. filed June 23, 1922. Cellular structure for pencil electrodes.

(Issued Jan. 30, 1923)

1,443,357. AUDIBLE SOUND INSTRUMENT; B. F. Gardner, Chicago, Ill. App. filed Aug. 4, 1921. Determining quantity of oil and water by means of telephone receiver.

1,443,361. SYSTEM FOR THE TRANSMISSION OF RADIANT ENERGY; J. H. Hammond, Jr., Gloucester, Mass. App. filed July 27, 1917. High degree of secrecy may be maintained.

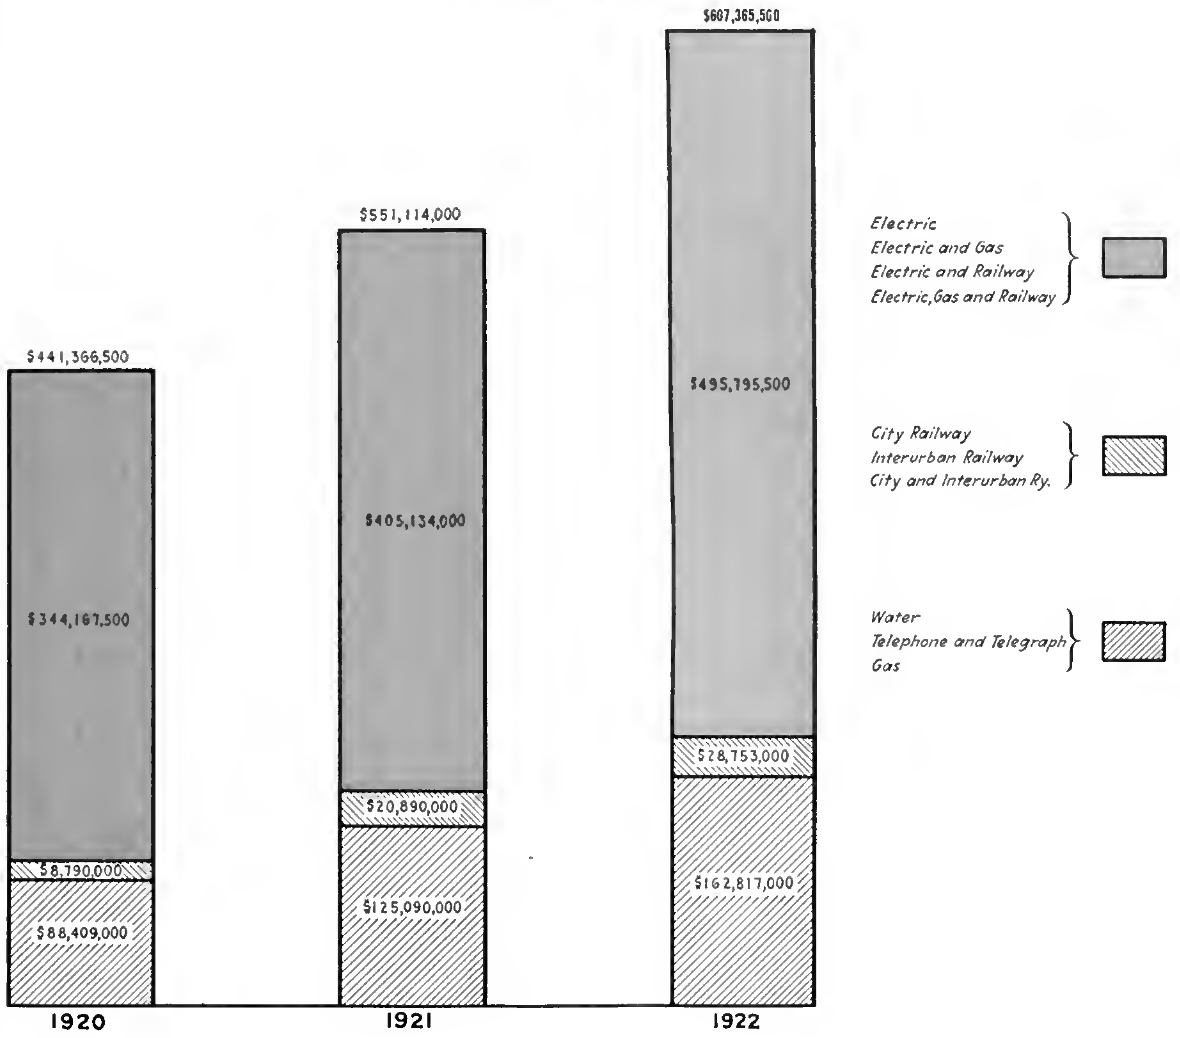
1,443,419. BURNISHING MACHINE; B. S. Lee, Beverly, Mass. App. filed May 6, 1921. Electrically heated setter for burnishing sole edges of boots and shoes.

# Business Facts for Electrical Men

Selected Statistics Presented Graphically for the Use of All Interested in Analyzing the Trend of the Electrical Business

## Steady Increase in Public Utility Bond and Stock Issues

(Blocks of $500,000 and over)



## Economic Stability of the Industry

PUBLIC utility financing during the past three years places that industry in a unique position. During 1921, when business was struggling in the slough of depression, the financing of industry at large was at an extremely low ebb. Statistics show that the financing done in the United States by industrials during 1921 was only about half of that reported for 1920 and about three-quarters of the 1922 financing. Public utilities, especially the electric light and power branch, were an outstanding exception to this decrease in the absorption of new money. Bond and stock issues of central-station companies during 1921 were about 18 per cent in excess of the 1920 financing, and 1922 was about 23 per cent over 1921. The high cost of money during the period of depression, while undoubtedly holding back much-needed extensions to the generating, transmission and distribution equipment of the operating companies, yet was not sufficient to retard materially the historic continuous growth of the industry. Data compiled by National City Company.

## Volume of Construction Points to Record Electrical Sales

ONE of the most outstanding economic facts of the present winter is the non-appearance of the normal seasonal drop in volume of construction under way or contracted for. Normally the fall and winter months witness a low ebb in construction. Last November did witness a material drop, but the increased volume reported during December and January points clearly to the year 1923 as one of unprecedented new construction. A reliable survey indicates that the total volume of building construction during 1923 will exceed five billion dollars, of which only about one-fifth will be absorbed in dwellings and apartment houses. Expansion in industry in general will call for new construction in excess of a half billion dollars. These data furnish another indicator of the record volume of business which is before the electrical industry both for apparatus and supplies and also for the sale of electrical energy.

# Self-Development

THE creative thinking that is the great power behind all industry is done by but a few men. Upon these few men, therefore, rests the responsibility for the development and the progress of civilization.

The mental tests made by the government during the war in drafting forces for military service produced statistics that embraced 1,700,000 men — men who were taken from every stratum of society and were graded for intelligence. The average mental age of Americans was found to be about fourteen. Only $4\frac{1}{2}$ per cent of our population rate above eighteen, and it is upon them that we must depend. From their ranks must come the superior minds who will carry onward the further advancement of the electrical industry for instance.

IT HAS been said of Abraham Lincoln, whose memory we have honored this week, that the very fundamental of his character was that he permitted himself to develop. Lincoln *permitted* himself to develop. And so he grew in knowledge, in confidence, in capacity, in influence and in usefulness to mankind. And out of the cabin on the frontier came through self-development one of that small group who do the thinking for the world, a great leader for all the people.

Opportunity and achievement do not come by inheritance. A man may enter life blessed with high mentality. He may have unusual advantages of environment and education. But his success in service, his value to society, will depend not alone on the extent of his ambition and his energy. It will be governed also by the degree to which he permits himself to develop and thereby take a higher place among his fellows.

THE greatest enemy of progress is the closed mind. The engineer, the manufacturer, the jobber or any one else who says, "This is my work," and will not learn and think beyond the day's need, is not only refusing to permit his own development, but is restricting his capacity for usefulness to the world that must depend upon his class for creative leadership. And the central-station executive who occupies his thoughts completely with operating, engineering and finance and does not build himself up for leadership in the community—he the head of a vital industry — is failing no less pitifully.

Men of the electrical industry are of that thinking class that carries the responsibility for progress — the small percentage of population that are blessed with superior minds. But the work that will carry civilization forward in the service of mankind will ever be done by individuals. The leaders will be those not born but self-developed to a superior usefulness. And, happily, development will come to any such man who will permit himself to grow.

# James William Perry

*A conservative leader among the electrical manufacturers, for twenty years an influence for constructive progress and good business practice.*

IF ONE looks closely at the electrical industry, he will see a scattered body of enthusiastic men steadily pioneering through forty years in a new science, a new art, and building it into a new industry. These have been years of experiment in invention, in production and in the commercial fabrication of an organized business, and as ever there have been two contributing forces counterbalancing each other. They are the eager-hearted, visionary men who are impatient of restraint and ever seek to hurry on to new adventures and the prudent, sure and thorough-thinking men who keep their feet upon the ground, an influence for conservatism. In combination they evolve a structure that is sound to the core.

James W. Perry, general manager of the electrical department of the H. W. Johns-Manville Company, for twenty years has been a prominent figure among the leaders of the conservatives. A clear thinker, sound in judgment and firm in decision, he has stood midway between the radicals and the reactionaries and done yeoman service in the upbuilding of this industry through the most vital period of its organization and development on national lines. Mr. Perry has exerted a great influence for sound business methods in the electrical industry. He has preached the policy of live and let live, opposing price cutting and all destructive practices. His counsel has been courageous and optimistic. He was a prime mover in establishing the first organized co-operation among the manufacturers of electrical materials, which resulted in the forming of the Associated Manufacturers of Electrical Supplies. He was the treasurer of this association and a member of its board from its inception until last September.

Mr. Perry was born in Parkersburg, W. Va., in 1868. In 1889 he joined the Johns-Manville company's Philadelphia branch, where he continued until the consolidation of this company with the Mansville Covering Company of Milwaukee, in 1902, led to his transfer to New York in charge of the electrical business of the new company. He has continued the active head of the manufacture and sale of its electrical and automotive products and is a director in the company and in several subsidiaries.

Mr. Perry is treasurer and a director of the Electrical Manufacturers' Council, a director of the Electrical Manufacturers' Club, and has long been active in the work of the N. E. L. A., at one time serving for five years as chairman of its exhibition committee. He is a member of the A. I. E. E. and the American Electric Railway Association.

# Editorial Comment

Electrical World, February 17, 1923

Volume 81 Number 7

### Wanted—a Yardstick

MANAGERS of public utilities under a common control and executives of properties that have enough points of resemblance to make comparisons of operations instructive are becoming more and more interested in analyses of performance of all phases of utility operation and service, for thus they hope to better the service and earnings of their own companies. There are many unit data which are suggestive in making such comparisons, but the industry needs more light upon the possibilities of grading public utilities. Some of the well-known groups of utility operators have found the existing units of comparison wanting, and at present the field is open for suggestions as to improved methods of approaching this continuously important problem.

### Selecting the Candidate for the Charles A. Coffin Medal

PRESIDENT FRANK W. SMITH has issued a letter to all electric light and power companies in the country indicating some of the factors which are to be considered in bestowing the Charles A. Coffin central-station medal. Readers will recall (see ELECTRICAL WORLD, Dec. 9, 1922, page 1293) that, according to the provisions establishing the Charles A. Coffin Foundation, "a gold medal . . . will be awarded annually to the public utility operating company within the United States which during the year has made the greatest contribution toward increasing the advantages of the use of electric light and power for the convenience and well being of the public and the benefit of the industry." It will be no small task to make the selection of this particular "public utility operating company," and there will doubtless be criticisms of the selection finally made. This much, however, should be said: that the annual bestowal of this medal will tend to bring into desirable prominence not only the utility receiving it but also and primarily the character of the service and the outstanding quality of this particular company. Thus others will be spurred on to adopt practices which are shown to be valuable and profitable—not for the mere winning of the next annual medal, but rather on account of the proved intrinsic worth of these practices. Of course, this is the principal value of all such medals, and the Charles A. Coffin medals and awards should, in the various lines in which they will be given, all serve to stimulate advance. It is proper and fitting that the name of Charles A. Coffin should be perpetuated in this manner as a constant reminder of his own contribution to the advance of electrical science and industry and as an encouragement to others.

It would also be a most fortunate circumstance if, in the work of the committees for the selection of the central-station company and for the selection of the electric railway company which are to receive the respective medals, some real contribution should be made toward the general question of rating of utilities for administrative or comparative purposes.

### Röntgen's Contribution to Humanity

GREATNESS is sometimes measured by accomplishment, but he enjoys the widest fame who does most for his fellow man. Thus the discoveries of Prof. William Röntgen, who died last week at Munich, will cause his name to be remembered long after the details of his work have passed into oblivion. His contribution to humanity was the discovery of a particular type of radiation produced by the discharge of electricity through a vacuum, or Crookes' tube. These rays, called "X-rays" because at the time their exact nature was unknown, have the quality of penetrating substances opaque to ordinary light and of being absorbed by certain other substances which are transparent to light. When used in connection with the photographic plate, shadow pictures or radiographs of the bones of the body or of metal objects embedded in the flesh or in wood may be obtained.

Although from the point of view of the physicist valuable contributions to our knowledge of X-rays have been made by Prof. J. J. Thompson and the Braggs of Cambridge, England, and Dr. Lane of Zurich, it is the use of the X-ray in surgery, in therapeutics and in dentistry which has been of greatest interest and benefit to mankind. Unfortunately this knowledge was not obtained without sacrifice, and many are the martyrs who have suffered burns and destruction of the flesh or even lost their lives in their endeavors to make the therapeutic value of the X-ray available to their fellow-men.

To Röntgen homage was due. Societies all over the world were named after him, and medals, honors and prizes were awarded him. Unlike many other benefactors of the race, he lived to see a most wonderful development of his discovery and to enjoy the fruits of his labor. His death adds another name to the gradually increasing list of departed scientists whose labors have been of signal benefit to humanity.

### Right-of-Way Purchases Related to Public Policy

"GET your right-of-way before any one knows what you are going to do" was the advice recently given an engineer who had a transmission-line project under consideration. The idea is the survival of a policy acted on by public utilities of various kinds in the early days, but it is one that has produced no small amount of trouble for and ill feeling toward these same utilities. It is doubtful whether there are any cases in which right-of-way for a transmission line has been

obtained where the property owners have been in doubt concerning the nature of the project after permission to cross the first piece of land has been secured. On the contrary, the air of deep mystery with which the old time right-of-way man surrounded his dealings usually resulted in suspicion and higher costs than an open policy would have caused. Moreover, right-of-way acquired in this manner is usually obtained with oral promises that are not written into agreements, and if they are violated, the ill feeling aroused lasts over long periods of years.

The purchase of easements or other rights for transmission-line right-of-way purposes by a power company ought to be a clean-cut business proposition in which the power company enjoys the confidence of those with whom it deals to such an extent that they, believing the advent of the power company to mean good to the whole community, will be willing to suffer some inconvenience, if necessary, in view of the greater good to come. In short, the power company in buying its right-of-way is conducting a legitimate business deal that is essential to the maintenance of its position. If the operation can be handled in this way, it can be made a means of better public relations. So long as it is handled in a secretive, hang-dog fashion there will always be unpleasant and unnecessary misunderstandings to live down.

## Agricultural Engineers Called to Judge Central-Station Practice

THE appointment by the American Society of Agricultural Engineers at its St. Louis convention in December of a committee to deal with the problem of central-station service and utilization of electrical energy on the farm is a move the significance of which cannot be ignored. This society is the body in which the engineers from the agricultural schools and experiment stations meet to discuss mutual problems, and it has had for some time a committee dealing with the problems of service from the individual electric plant.

Back of the appointment of the committee lies a story of many demands from individual farmers for information on the use of electricity. Not only has this been the subject of discussion with the pioneers in the application of engineering principles to agriculture, but central-station practices and faults have also been under review. As might be expected, varying degrees of criticism of central-station policies have been expressed by the farm experts, and by virtue of their position the engineers in the agricultural schools and experiment stations have often been placed in the position of judges.

Several cases have come under observation in discussion with agricultural engineers in which there is serious misunderstanding of central-station conditions or in which central-station men who ought to know better have adopted arbitrary attitudes that provide just ground for criticism. The central station has a real story and a real problem in this situation. The agricultural engineers, many of them electrical engineers who have turned to the agricultural engineering field after graduation, are capable of investigating, appreciating and judging that story. By virtue of their position and the confidence reposed in them the farmer will look to them for advice and final determination as to the reliability of the representations of the central-station men.

From a central-station standpoint, therefore, there is only one outcome to the situation. It is that in every state central-station organizations should work with the agricultural engineering and experimental schools in the search for the right methods of bringing electricity to the farm.

## Need of Simple Methods for Determining Conductor Sizes

TO THE man building up a distribution system the problem of the proper size of wire to use for extensions presents itself several times a day. In the past this problem was too often settled by the application of some set rule passed down from foreman to foreman, sometimes modified as conditions changed materially, but generally having its origin in some vague, general consideration of strength of material, of convenience in stock keeping or safe carrying capacity.

Nowadays it is hardly necessary to point out to the man laying extensions that economical consideration should be the basis in the selection of wire sizes. However, he must fail in his work unless he is given some convenient means of applying economies to such design. While each one of these may seem of quite small importance, the aggregate over a year's work is capable of showing economies involving thousands of dollars.

Any system should be able to work out constants which can be applied generally to its specific conditions. The result of these economical solutions, combined with the element of judgment necessary to determine on the number of sizes to be used, should show real economies in the distribution system.

## Peterson Coil Not a Panacea

TO GROUND or not to ground is a question that has always created discussion. Now that several new types of equipment are available which enter more or less extensively into the solution of the grounding problem and about which extended operating experience is not yet available, the question is revived with more than usual interest.

One of the most prominent new absorption types of transmission-protection equipment is the Peterson earth reactance coil. This is coming into considerable use in some places. A general opinion exists that it is best adapted to low-voltage systems of limited extent, but field experience is needed to determine its limitations in application; and although it cannot be said to have received even a moderate indorsement for high-voltage systems, it has several features that offer possibilities for greater development.

The chief claim is that the coil suppresses an arcing ground through the agency of a local resonant circuit condition and that it decreases the possibilities of electromagnetic induction in neighboring circuits by eliminating the third harmonic. As against these advantages arguments have been advanced to the effect that the system insulation must still possess a high factor of safety as there is a tendency to produce voltage surges. Moreover, there are certain complications in making changes in the coil calibration as the system arrangements or conditions change, for it is very difficult to obtain sufficiently delicate adjustments to extinguish the arc for all conditions of frequency and wave front that may arise on a given circuit.

Variable-frequency transients, unbalanced grounds and resultant corona effects, and energy magnitudes of great variety—all these elements must be encountered by the resonant circuit adjustment. In addition, electrostatic effects still persist to produce disturbances in neighboring circuits, and the telephone engineers are unable to agree on the universal application of the Peterson coil to improve inductive co-ordination.

In the near future actual operating experiences with the coil should be available from several systems, and more definite conclusions can then be formed. It is a cause for congratulation, however, to see the co-operation of telephone and transmission engineers in the common problem of insuring the more satisfactory operation of transmission systems. In the long run what is best for the transmission systems is also best for the telephone system, and vice versa.

### Penalizing the Electric Truck

THE lawmakers of this land do not yet appreciate that there is a difference between the electric vehicle and the gasoline car that should be reflected in the tribute which they pay toward the maintenance of the roads. The new motor-vehicle license law for 1923 in the State of New York, for example, is grossly unfair to both the electric truck and the electric pleasure car. The new tax is fixed on the basis of weight, with the result that a license for a five-ton (capacity) electric truck costs $104, as against $88 for the gasoline truck. The pleasure-car license figured on the same basis is even more unfair. The fee for 1923 is from three to seven times the fee for 1922, depending on the model of the car, that is, the year it was manufactured and its size. The unfairness of the new law is even more evident when the facts underlying its theory are analyzed. Two factors are assumed in shaping the law, one that the tax is in line with paying for wear and tear on the state highways and the other that such wear and tear is proportionate to weight. On both these counts the electric truck is unjustly rated. In the first place, its rapid development during the last three years has been for town and city local haulage and not for interurban and state highway use. In the second place, with any car the wear and tear on roads is not proportionate to weight alone, but is a product of weight and speed and the mechanical conditions of driving. Therefore, in spite of its greater gross weight per net ton carried, due, of course, to the weight of the storage battery, the "electric" is far easier on roads than any other type of truck. The simplest proof of this is that tires give a longer life on an electric truck than on a gasoline truck of the same capacity, and obviously the smooth starting torque of the electric drive and the absence of shock and vibration are the mechanical reasons for this longer tire life.

It is, of course, too late to abate the injustice of the New York law this year, but the issue is not confined to that state. Across the country it has become common practice to reckon license fees on the basis of car weight, and this method of estimating the road-destroying influence of a vehicle discriminates against the "electric" because of the natural characteristics of the car and the kind of service in which it is used. It has become important, therefore, that the manufacturers and users of electric vehicles take the initiative in devising some simple method of determining a license fee that will be fair to both electric and gasoline cars. They must then proceed to lay the facts before all legislative bodies with a constructive recommendation that will provide a fairer basis for taxation.

### What Will Be the Future Ash-Handling System?

ACCORDING to opinions expressed at the recent convention of the American Society of Mechanical Engineers, the most desirable method of handling ashes is to use bottom-dump ash hoppers discharging into industrial or railroad cars. Such equipment is easily operated and maintained, does not require excessive headroom and is adapted to emergency ash-removal methods. When imperative, the ashes can even be dumped on the floor.

The importance of having hoppers of ample size cannot be overemphasized. No hopper should be so small that the corresponding furnace has to be shut down or operated at reduced rating because an accident to the ash-removal equipment has prevented dumping the hopper for several hours. Some companies are going so far as to provide three and even ten days' storage in their ash hoppers. But such large capacity is hardly feasible except with submerged ash pits such as the West Penn Power Company uses.

Submerged ash pits are said by their owners to require no more investment than any other types of ash pits. Besides they prevent emission of carbon monoxide, corrosive gases and flames.

Mechanical conveyor systems will always find a place in plants which are so situated that the simpler form of ash-removal equipment favored at the A. S. M. E. meeting cannot be applied. When space requirements are limited they may be used to advantage, since the apparatus can sometimes be employed for both coal and ash. However, the maintenance expense continues to be a drawback.

Of late considerable attention has been directed to conveyors of the steam-jet and hydraulic-sluice type, apparently because of their simplicity and small space requirements. While they involve no moving mechanism to wear out, there is still the relative motion of abrasive ash and conduit. Furthermore, the steam economy of the jet type may be very poor unless the system is properly designed, the joints kept tight, worn nozzles replaced, and so forth. With proper attention given to the tightness of joints and provision made for readily replacing worn elbows, experience so far seems to indicate that ash containing fairly large clinkers can be handled. The Hell Gate installation of open-flume ash sluice is a noteworthy example of the hydraulic type which has operated very satisfactorily so far in the bulk supply station of the United Electric Light & Power Company.

With either form of fluid conveyor, however, it would seem desirable, in view of the limited experience with this equipment in the public utility field, to provide for some emergency method of ash removal in case the conduits should clog up or some similar contingency should occur.

Speaking generally, that ash system will be best which assures the highest reliability for the least annual expense (including fixed charges) and which can be readily supplemented by some expedient method in an emergency. How existing systems rank in desirability cannot be accurately determined until data like those mentioned above have been carefully compiled.

# Electricity Offers Opportunity to Beautify City Structures by Night

The new $7,000,000 Hampden County Memorial Bridge at Springfield, Mass., crossing the Connecticut River, affords an admirable example of the adaptability of ornamental and utilitarian electric lighting to works of civic pride. This reinforced-concrete structure forms a direct highway in and out of Springfield and shortens the connection between the urban center and the Berkshire Hills region and points west. Four central towers 80 ft. high carry each a 500-watt type C multiple lamp operated at 110 volts and in a globe 2½ ft. in diameter. The sides of the bridge are equipped with inverted magnetite arcs of 5 amp. rating, mounted on posts at a height of 18 ft. above the street. This photograph was taken under floodlight.

# The Future Distribution System

## An Analysis of All Types of Distribution Systems from All Standpoints Indicates that One Type of Distribution System Is Best—Comparison of Methods in Tabular Form

By WILLIAM C. L. EGLIN
*Vice-President and Chief Engineer Philadelphia Electric Company*

IT IS rather remarkable to find that the evolution of the light and power industry is tending in a direction to prove that in every respect the original Edison system possessed the fundamental requirements of engineering and economics which would be specified in an ideal system of today.

The Edison system fed all loads for which it was adapted from generating stations containing only one type of equipment, and it did this from a single type of distributing system. These two fundamental practices are granted to be ideals in modern systems, and the trend of development is in this direction; but investigation proves that action on these fundamental facts has been hampered by the existing installations, and only very haphazard analyses have been made of the possibilities for accomplishing the desired results more rapidly.

The distribution system of today comprises all the plant necessary for delivering energy from the generating station to the meter of the consumer. In the historical development of this phase of the electrical system several systems have been used, some of which have been discarded, but others still exist in their original form, and in many properties several types are found in operation.

For using both alternating current and direct current well-known systems are:

1. *Series System.*—This system requires a series connection for all equipment, utilizes constant current and requires a voltage that varies with number of energy devices connected.

2. *Two-Wire Parallel System.*—This system requires a parallel connection for all loads, utilizes a variable current and requires a constant voltage.

3. *Three-Wire System.*—This system is similar to the two-wire parallel system but allows double voltage.

4. *Feeder and Main System.*—This system requires constant voltage on the mains and a voltage on the feeder which depends upon the load.

In addition to these systems the multiple-wire polyphase alternating-current system is in great use. Three, four, five or more wires may be used in this system and many variations in connections are available.

### Fundamentals in Choice of System

From the available distribution systems choice must be made to secure the best results for the operations of a light and power company. Both financial and operating considerations enter into the study, and in addition the bearing of the decision upon associated activities must be weighed. From an electrical industry standpoint the public, the manufacturers and other light and power companies are concerned in the decision.

The cost of money is a major item in energy production and distribution, and from this standpoint it is essential to secure maximum output from all plant equipment per dollar invested. This points toward the use of one type of generating equipment and a single distribution system in order to take advantage of diversity in loads and to obtain the high load factors possible through the use of interconnected generating stations carrying the diversified loads.

A service element with many ramifications affecting associated activities is the requirement that there should be some fixed standard or standards of voltage applied to energy utilizing devices. A safe maximum voltage at which accidental contact would not be injurious to life would be the logical standard. This would raise the permissible minimum voltage to perhaps 150, either alternating or direct current. Of course, a slight allowance for the effect of line drop would be advisable in connection with the fixing of a standard voltage, and these variations should be kept above the standard value. The use of the highest possible safe voltage would reduce costs to the consumer, because voltage is a direct element in fixing plant investment and in addition is influential in fixing the cost of many energy-utilizing devices. It would seem advisable at this time to give further consideration to the choice of a standard voltage.

### Series System Should Be Discarded

The series system should be eliminated from the industry. Few utilization devices are applicable to the system, and it is almost exclusively used for street lighting, with a consequent load factor of about 50 per cent, no diversity factor and about 10 per cent actual utilization of the copper. It requires a duplication of substation equipment and an added expense in overhead or underground construction. The parallel system must be used to supply other loads, and the present state of the art indicates that the street-lighting load could be carried on the constant-potential system with only minor modifications in circuit and plant arrangements. The development and extensive use of the incandescent lamp and the use which is being made at the present time of the constant potential mains for street lighting even under the handicap of control by time switches, pilot wires or manually, shows that satisfactory operation has already been obtained. The development of a satisfactory remote control switch to be operated over the mains themselves is the sole remaining step and this seems to have been satisfactorily solved on an experimental basis at least.

### Direct-Current System Has Limitations

The direct-current system meets all the requirements imposed by the various uses of the consumer and in certain favored locations where the generating stations

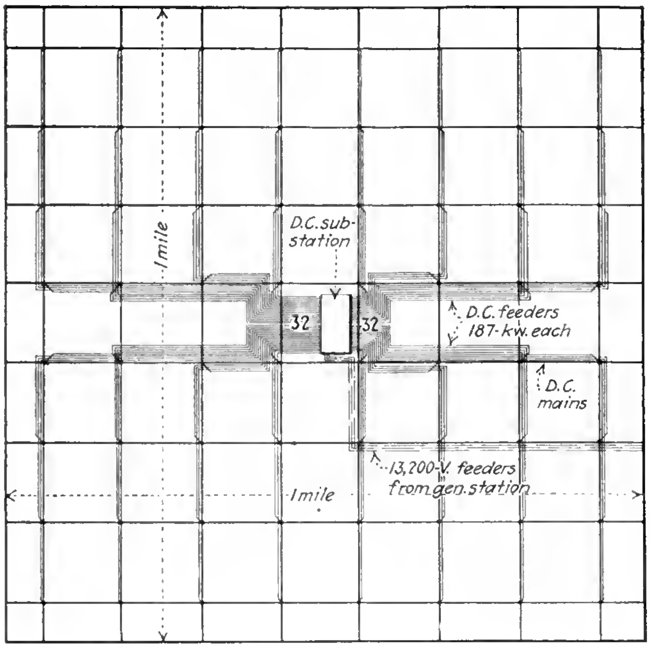

FIG. 1—BUSINESS DISTRICT SUPPLIED FROM ONE D.C. SUBSTATION
Peak load, 12,000 kw.; annual use, 46,000,000 kw.-hr.; load factor, 44 per cent; sixty-four feeders, average length 0.5 mile, maximum length 0.87 mile; weight of feeder copper, 560 tons; annual feeder loss, 6,400,000 kw.-hr. (14 per cent).

can be located at the load centers meets other economical conditions.

However, in the large systems the generating stations cannot be located at the load centers, and with the great increase in load density now found in congested districts the territory that can be served with economy by direct current has been steadily decreasing in area. The economic size of substation supplying the direct-current system is much smaller than is now common practice, and this method becomes more and more expensive as the load density increases.

To make concrete the limitations of the direct-current system assume that a business district including an area of one square mile and having a sustained peak load of 12,000 kw. is to be supplied with power at 230 volts. The annual consumption is estimated to be 46,000,000 kw.-hr., corresponding to a load factor of 44 per cent. The load density is assumed to be uniform, corresponding to 187 kw. supplied at each street intersection, there being eight blocks per mile. Three methods are compared:

1. An Edison direct-current system using one substation at the load center (Fig. 1).

2. The same using four substations each at the load center of its district (Fig. 2).

3. Three-phase, four-wire alternating-current system having a bank of transformers at each feeding point (the street intersections) supplied from a single substation at 2,300 volts. A complete network of 2,300-volt mains is assumed, thus making use of the maximum of copper (offset, of course, by the advantages of reliability and diversity). The power factor is assumed to be 83 per cent (Fig. 3).

Practically the same amount of copper is required in the low-tension mains in each case, and the losses in these mains would virtually be the same. The feeder copper and losses of the above paragraphs 1 and 2 are to be compared with the copper and losses in the 2,300-volt mains, feeders and transformers of paragraph 3, the comparison being as follows:

| System | (1) | (2) | (3) |
|---|---|---|---|
| Current | D.C. | D.C. | A.C. |
| Substations | 1 | 4 | 1 |
| Number of feeders | 64 | 64 | 10 |
| Average length, miles | 0.50 | 0.25 | 0.42 |
| Maximum length | 0.87 | 0.37 | 0.62 |
| Weight of feeder copper, tons | 560 | 280 | 94 |
| Annual feeder loss in millions of kw.-hr. | 6.4 | 3.2 | 1.6 |
| Annual feeder loss, per cent | 14.0 | 7.0 | 3.5 |

Figs. 1, 2 and 3 show the feeder and main systems of the various methods by means of single-line representa-

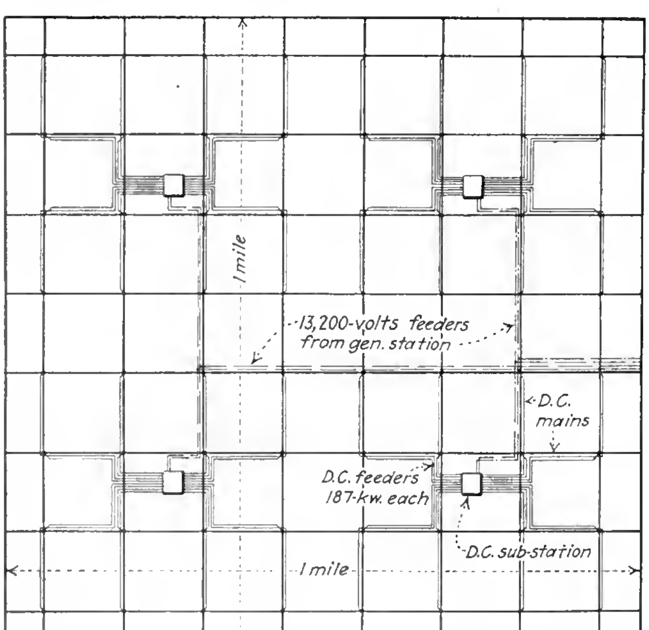

FIG. 2—BUSINESS DISTRICT SUPPLIED FROM FOUR D.C. SUBSTATIONS
Peak load, 12,000 kw.; annual use, 46,000,000 kw.-hr.; load factor, 44 per cent; sixty-four feeders, average length 0.25 mile, maximum length 0.37 mile; weight of feeder copper, 280 tons; annual feeder loss, 3,200,000 kw.-hr. (7 per cent).

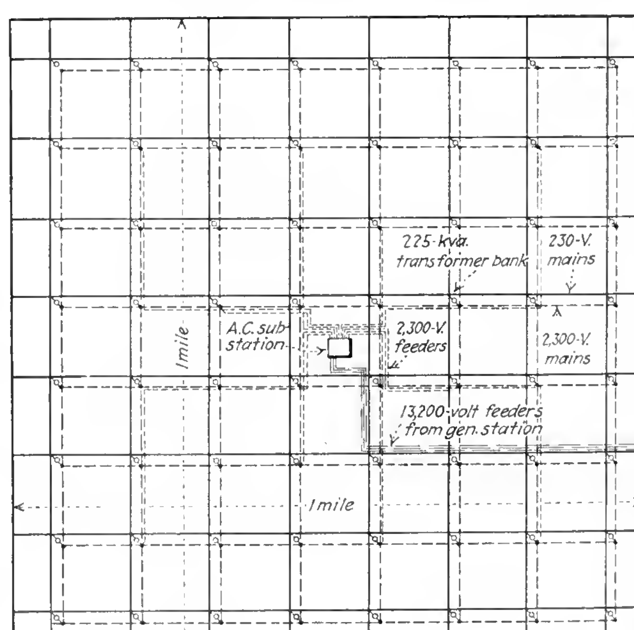

FIG. 3—BUSINESS DISTRICT SUPPLIED FROM ONE A.C. SUBSTATION
Peak load, 12,000 kw., at 83 per cent power factor; annual use, 46,000,000 kw.-hr.; load factor, 44 per cent; ten feeders, average length 0.42 mile, maximum length 0.62 mile; weight of copper in 2,300-volt feeders and mains, 94 tons; annual loss in transformers and 2,300-volt system, 1,600,000 kw.-hr. (3.5 per cent).

tion. The comparison of the figures shows the relative street congestion due to the various methods, and Fig. 4 gives a comparative idea of the relative weight of copper necessary in the different systems and compares the losses also.

The power companies have usually confined the direct-current system to the built-up, heavily loaded districts and have installed alternating-current distributing systems in all of the territory surrounding this built-up section, generally covering a much larger area. The load in this outside territory thus supplied by alternating current is generated usually at the same generating station and transmitted at high voltages to substations, where the voltage is stepped down to a secondary transmission system and connected through line or manhole transformers to the consumers' mains. Here we meet, however, with the greatest differences in methods and an almost complete lack of standardization. There are single-phase lines, two-phase lines, three-phase lines and four-phase lines made up of two-wire circuits, three-wire circuits, four-wire circuits and five-wire circuits. Surely one of these methods must be the most economical in first cost, and the determination and use of this line, as has been pointed out, is of the first importance to the power company.

Polyphase alternating-current supply may be adapted for all of the uses of direct current either directly or by using local motor-generators or rectifying equipment. Alternating-current service is or may be as satisfactory to the consumer as direct-current service, particularly as opportunity is afforded the large consumer to obtain his power at wholesale by assuming the burden of transformation or conversion if he so desires. This conclusion is further justified by the fact that many cities have large business districts containing all classes of consumers which are outside of the direct-current district (if there is one) and that all consumers are satisfactorily served.

The following cost figures are based on an analysis of an existing system comprising a direct-current series system, an Edison system and an alternating-current system consisting of a four-phase, five-wire secondary network supplied mainly by two-phase, three-wire primaries but partly by four-phase, five-wire primaries. Thirteen-thousand-volt, three-phase generation and transmission is used, from which some power is also sold direct.

Generating and substation costs have been found to be as follows per kilowatt: Generating stations, $140; arc substations, $100; direct-current substations, $70; alternating-current substations, $40.

These costs are based on completed station capacity and are the average for several stations built at various times, under varying conditions of prices and in localities with varying load conditions.

Using these station costs, adding the cost of transmission and distribution systems, including substations and distribution transformers, and making allowance for the added generating capacity, etc., necessary to supply the losses in the respective systems, the investment costs per kilowatt delivered at the substation bus and at the customers' services are:

| | Point of Delivery Substation Bus | Point of Delivery Customers' Service |
|---|---|---|
| Series system | $633 | $666 |
| Direct-current system | 356 | 404 |
| Low-tension alternating-current system | 298 | 347 |

Similarly, the operating costs, including fuel, attendance and maintenance of both stations and lines but not including fixed charges on investment, based on the year 1920, were found to be in cents per kilowatt-hour:

| | Point of Delivery Substation Bus | Point of Delivery Customers Service |
|---|---|---|
| Series system | 1.96 | 2.07 |
| Direct-current system | 1.57 | 1.78 |
| Low-tension alternating-current system | 1.28 | 1.49 |

These operating costs include the effects of the comparative efficiencies of the three kinds of substations. These over-all efficiences are approximately as follows, in percentage: Series substation, 74.8; direct-current substation, 81.4; alternating-current substation, 98.

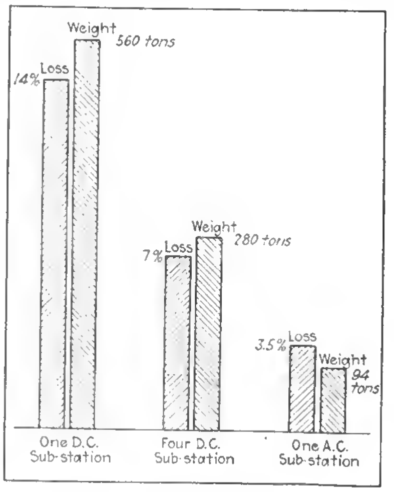

FIG. 4—COPPER WEIGHT AND ENERGY LOSS

Comparison of weight of copper and annual energy loss in various systems based on 500,000 circ.mil mains and 1,000,000 circ.mil d.c. feeders.

These figures show clearly that the low-tension alternating-current system is much cheaper both in first cost and in operation than the direct-current system, although the conditions of delivery into a densely loaded district favor the direct-current system. Moreover, the alternating-current system under consideration is not the particular alternating-current system which has been found by analysis to be the most economical.

The figures also show that the series lighting system is very expensive compared to either of the other systems.

The various methods which can reasonably be used for the primary distribution system are four—(1) two-phase using either three or four wires, (2) four-phase using five wires one of which is grounded and usually common to all other circuits of the same class of a par-

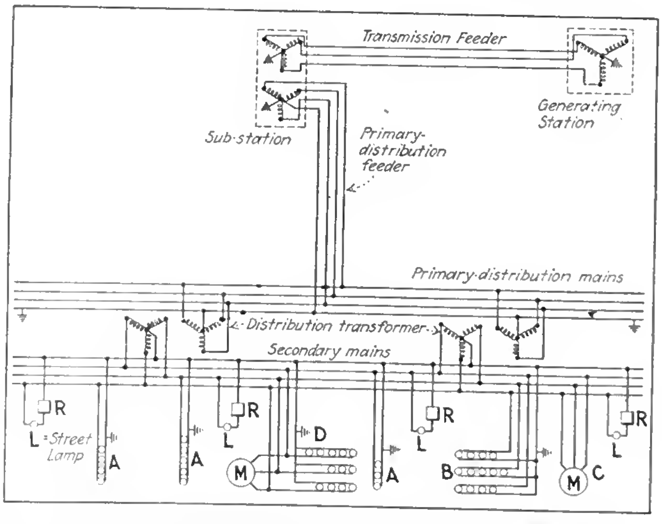

FIG. 5—UNIVERSAL ELECTRIC SYSTEM GIVES BEST AND MOST ECONOMICAL LAYOUT FROM DISTRIBUTION STANDPOINT

ticular pole or duct line, (3) three-phase using three wires, and (4) three-phase using four wires one of which is grounded and common as in (2). The relative economy of these various methods may be most clearly shown by a specific numerical comparison. The use of approximately 2,400 volts between phase wires is almost universal, and this voltage will be used as the basis of comparison. Assume that the line wires are No. 00, as many being used as are required by the particular system under discussion. The carrying capacity for such a wire strung on poles will be assumed to be 225 amp. and the drop with this current, 14½-in. spacing and 80 per cent power factor, is 156 volts per mile of wire. This drop would be increased slightly in some cases by the increased spacing due to poles, spacing between phases, etc. These results are compared in Table I and some further comparisons are made.

Two of these methods indicated by Table I—the four-phase, five-wire, and the three-phase, four-wire—are nearly on a par and stand out so much better than the others that one of them should unquestionably be adopted. The three-phase, four-wire method is simpler both in the substation, where one less bus is required, and on the line, where either four transformers are needed for each bank of the four-phase system or else the circuit must be split into two-phase circuits of the three-wire type, involving then some of the disadvantages of this method, which the comparison shows to be the worst of all. The question of safety is discussed later.

### Secondary Distribution System

The ideal system for general distribution *at lighting voltage* must comply with several requirements: (a) It must be polyphase, so as to permit the operation of motors; (b) it must be a symmetrical polyphase system, so that the line drop due to a balanced load will not cause distortion of the voltages either in magnitude or phase, and the unbalance in voltage caused by unbalanced loads must be small; (c) the voltages available must be suitable for both light and power requirements and must not exceed a fairly safe maximum; (d) the energy delivered to both light and power loads must be capable of being measured by a single meter; (e) the investment cost per kilovolt-ampere delivered must be low; (f) the efficiency must be high; (g) the number of conductors must be as small as possible; (h) one conductor must be a neutral which can be grounded in such a way as to limit the voltage of all other conductors to ground to a value below 150 volts, and which preferably is symmetrical in voltage relations to the others; (i) this system must be capable of simple and economical derivation from the primary distribution system and this in turn from the transmission system.

TABLE I—STUDY OF PRIMARY SYSTEMS

| System | 1-a | 1-b | 2 | 3 | 4 |
|---|---|---|---|---|---|
| Number of phases | 2 | 2 | 4 | 3 | 3 |
| Number of wires | 4 | 3 | 5 | 3 | 4 |
| Capacity per circuit, in kva. | 1,080 | 765 | 2,160 | 933 | 1,620 |
| Per cent drop per mile | 13.0 | 9.2 | 6.5 | 11.2 | 6.5 |
| Number of regulators | 2 | 2 | 4 | 3 | 3 |
| Circuit capacity per wire, in kva. | 270 | 255 | 432 | 311 | 405 |
| Per cent drop per mile per 1,000 kva. | 12.0 | 12.0 | 3.0 | 12.0 | 4.0 |
| Number of circuits per 10,000 kva.* | 9 | 13 | 5 | 11 | 6 |
| Number of wires per 10,000 kva.* | 36 | 39 | 25 | 33 | 24 |
| Number of regulators per 10,000 kva.* | 18 | 26 | 20 | 33 | 18 |

* Nearest whole number.

The only polyphase methods which can be considered are: (1) Two-phase, three-wire, at 115 volts or 230 volts to neutral; (2) two-phase, four-wire, at 115 or 230 volts; (3) two-phase (strictly four-phase), five-wire, at 115 volts to neutral; (4) three-phase, three-wire, delta, at 115 or 230 volts per phase; (5) three-phase, four-wire, delta, at 230 volts, the fourth wire being a lighting neutral tapped from one phase; (6) three-phase, four-wire, star, 120 volts to neutral and 208 volts between wires.

Table II shows a comparison of each of these methods together with the three-wire system (using either direct current or single-phase alternating current) with respect to the requirements enumerated.

### Comparison of Methods

Methods No. 1, No. 2 and No. 4 must be eliminated for the reason that they do not afford satisfactory voltages as well as for other reasons; method No. 5 is not a balanced system and cannot be metered on a single meter, and method No. 3 is needlessly complicated with its five wires, leaving method No. 6, the three-phase, four-wire star system, which seems to fill most satisfactorily all of the requirements and compares favorably with the direct-current three-wire method, the one drawback being its adaptation to the present normal voltages of lighting and power apparatus.

Since the same method was found to be most desirable for the primary distribution system, it seems evident that the general adoption of the three-phase, four-wire system is the only logical course. We will then have, following the present practice in generation, a 13,000-volt or 26,000-volt, three-phase, three-wire generation and transmission system with grounded neutral, a 2,400/4,150-volt, three-phase, four-wire primary distributing system with grounded neutral and a three-phase, four-wire secondary system with grounded neutral, operating at some voltages such as 120/208 to 130/225—the same system throughout. This system is shown in Fig. 5 complete from the generator to the various ultimate consuming devices.

### Safety Must Be Considered

In the direct-current low-voltage distributing system there is practically no danger to life. With alternating-current systems this is a serious hazard and must be considered of first importance in the design of any system; so that the safe maximum for the consumers' devices as it affects the life hazard should be determined.

Next in importance to the life hazard is the fire hazard. It has been proved that any system of distribution must be capable of having its neutral grounded so as to eliminate all fire hazard due to the accidental occurrence of grounds on different conductors. This is of equal importance in either direct-current or alternating-current systems.

Considering in detail the primary distribution system, each of the methods considered uses the same phase voltage. Some are operated normally grounded and others normally free from grounds. However, in times of trouble the normally ungrounded system may be grounded on any wire and wires may cross. The lineman who must clear the trouble may therefore be exposed to the maximum voltage possible because of any combination of grounds and crosses, and usually under circumstances of darkness, storm and excitement, such

TABLE II—COMPARISON OF METHODS

| (a) Method | No. 1 Two-Phase, Three-Wire, 115 or 230 Volts | No. 2 Two-Phase, Four-Wire, 115 or 230 Volts | No. 3 Four-Phase, Five-Wire, 115 and 230 Volts | No. 4 Three-Phase, Three-Wire, 115 or 230 Volts | No. 5 Three-Phase, Four-Wire, Unsymmetrical | No. 6 Three-Phase, Four-Wire, Symmetrical | D. C. or Single-Phase, Three-Wire, 115 and 230 Volts |

| (i) Transformation | 6.7% lost capacity | 6 7% lost capacity | 6.7% lost capacity | O. K. | O. K. | O. K. | Complex |

Note.—Except as noted, the relative investments and losses are calculated on the basis of exactly equal current density in all conductors except the neutral which is equal in size to the other wires. These figures will be subject to modification to suit commercial wire size.

that the danger is even greater than that corresponding to the voltage.

Tabulating the conditions which exist or which may exist with the various methods, we have:

| System | 1-a Two-Phase, Four-Wire | 1-b Two-Phase, Three-Wire | 2 Four-Phase, Five-Wire | 3 Three-Phase, Three-Wire | 4 Three-Phase, Four-Wire |
|---|---|---|---|---|---|
| Normally grounded | No | No | Yes | No | Yes |
| Maximum possible voltage between wires | 3,400 | 3,400 | 4,800 | 2,400 | 4,150 |
| Maximum possible voltage to ground | 3,400 | 3,400 | 2,400 | 2,400 | 2,400 |
| Normal voltage to ground | | | 2,400 | | 2,400 |

The two-phase method using either three or four wires is very uncertain at times of trouble, and the voltage to ground may be larger than the normal phase voltage. The three-phase, three-wire method can introduce no voltage hazard higher than the phase voltage, but all three of these methods have the hazard due to unknown and uncertain conditions. Moreover, two fairly high resistance grounds or swinging grounds may exist on different wires which will not pass current sufficient to open the circuit breakers at the substation but will pass enough to burn off the wire in the resultant arc. In the case of either of the normally grounded systems no abnormal voltage conditions can exist and the accidental grounding of a phase wire is not so apt to arc and burn off the wire, since the first (the normal) ground has a positive, low-resistance path. While this may cause more frequent interruption, the damage is not apt to be so great nor the duration of the interruption so long.

The four-phase, five-wire method has the disadvantage compared with the three-phase, four-wire method that the maximum voltage between wires is considerably higher, which causes a greater hazard and will tend to increase the difficulty of maintaining insulation through tree exposures, and the larger number of wires increases this difficulty as well as the hazard.

The analysis given in this paper of the various polyphase methods of distribution, both for transmission and for distributing at primary and secondary voltages, proves conclusively that the three-phase, four-wire system best fulfills all the requirements as to reliability, safety, economy of pole and duct space, and low operating and maintenance costs; that it provides the largest capacity per dollar invested, and that it can be adapted, with suitable rules and regulations, to meet all of the conditions of central-station service, so that load of any character, not excepting street lighting, may be attached to a single distributing system, allowing it to enjoy all of the advantages of diversity factor, which is essential for the most economical operation of central-station service. This system may be extended into new territory as a single-phase system for light loads using a two-wire circuit, since it is capable of supplying domestic consumers and street lighting, with all the investment of permanent character, and may be supplemented later by the addition of two wires so as to take care of increased load as the territory is developed, enabling a common system to serve the entire area irrespective of the character of load, thus making for economy, simplicity and reliability.

In conclusion, such a system would eliminate many of the overhead wires which are now used and to which both the public and municipal authorities are constantly objecting, so that it would be possible, with substations suitably located, to distribute 20,000 kw. to 30,000 kw. from a single substation with pole lines requiring not more than two cross-arms, enabling the companies to continue distributing overhead over large territories at a lower investment cost than would be necessary in the event of underground distribution.

## Developments of Electric Furnaces During 1922

DEVELOPMENTS during the past in the electric furnace for steel melting have not been lacking, according to views expressed by C. E. MacQuigg in a recent article in the *Iron Age*. New ideas on the induction furnace have been carried out. The position of the electric furnace in the steel industry has been de-

cisively stated by Dr. Mathews before the American Iron and Steel Institute, who is an acknowledged authority on the subject. Elimination of the crucible plant by the electric melting furnace seems about as remote as ever. From the tonnage standpoint, however, the electric furnace will naturally make a constantly larger percentage of the fine steels.

Regarded from one angle, the increased use of the electric heat-treating furnace has had to wait on educational propaganda. The reaction in the past toward a suggested installation for electric heat treating has usually been that the outlay would be prohibitive. Upsets in the relative cost of fuels have brought home the fact that the first cost alone and the fuel costs will not determine final economy per unit of product. While locality determines fuel cost, important factors must often be sought elsewhere in labor costs, quality of the work and ratio of the accepted to the rejected product. Among the considerations urged for electric treating are uniformity of operation, perfection of control, better furnace conditions, lack of danger of overheating the work and absence of gases and dirt.

# Electrons from Hot Filaments

### Thoriated Tungsten Gives 130,000 Times Electron Emission of Plain Tungsten — Other Materials Are Being Studied

WHEN metals are heated in high vacuum electrons, or atoms of negative electricity, evaporate from their surfaces. If there is another electrode in the evacuated space to which a positive charge is given the electrons drift over to this electrode (anode) so that a current flows between the two electrodes. Dushman has recently derived an equation which should supersede the well-known Richardson equation, giving the relation between the electron current and the temperature of the cathode. The advantage of this new equation is that there is only one constant which we need to know for each different cathode material.

The electron emissions from a large number of different materials have recently been measured. The thoriated tungsten cathode gives a current at a temperature of 1,500 deg. absolute which is about 130,000 times greater than that secured from ordinary tungsten. Some of the cathode materials have even much greater emissions.

In order to get all the current that a cathode is capable of giving, it is necessary to apply to the anode a high enough voltage to overcome what is know as the space charge effect. By putting gases inside the tubes positive ions are formed in the space between the electrodes by bombardment, and these neutralize the negative space charge and allow the current from the cathode to pass across the space with much lower anode voltages. In other words, the effect of gases is to increase the current-carrying capacity of the two. Such an effect is used in the Tungar rectifier. Care must be taken what gas is used, for many gases have the effect of cutting down the emission to a small value.

If very high voltages are used on the anode, so as to produce intense electric fields, it is possible to pull electrons out of the cathode. In fact, it is possible to pull electrons even out of cold cathodes—that is, cathodes at ordinary temperatures. The currents obtained in this way from the cathode come from very minute areas, but in these areas the current density amounts to more than 100,000,000 amp. per square inch.

The thoriated tungsten filament is a tungsten filament containing 1 per cent or 2 per cent of thorium, usually in the form of oxide. When such a filament is heated to about 3,500 deg. C. a little of the thorium oxide is changed into metallic thorium. In the meantime, however, any thorium on the surface of the filament evaporates, leaving only pure tungsten. If the filament temperature is then lowered to about 1,800 deg., the thorium gradually wanders or diffuses through the filament, and when it reaches the surface, if the vacuum is very perfect, remains there and gradually forms a layer of thorium atoms which never exceeds a single atom in thickness. The thickness of this film is therefore about one one-hundred-millionth of an inch, and yet this film increases the electron emission of the filament about 130,000 times.

Of course, this useful film is very sensitive and needs some protection to keep it in good condition. Very slight traces of water vapor or other gases would oxidize and destroy it. This can be avoided by putting in the bulb some substance that will combine with the water before this has a chance to attack the thorium film. Such a substance is metallic magnesium. Furthermore, it is necessary to avoid heating the filament to too high a temperature for otherwise the film might evaporate. It is therefore best to operate such filament within a rather narrow range of temperature close to 1,700 deg. C. where the ratio of evaporation is very small and where the temperature is high enough for the thorium gradually to diffuse to the surface and offset the effect of slight traces of residual gases.

The thoriated tungsten filament open up many new fields of scientific investigation. By measuring the electron currents it is possible to determine accurately exactly how much thorium is present on the surface. An amount of thorium corresponding to only one-thousandth of the surface covered with a layer one atom deep is easily measurable in this way. It is possible to knock off a thorium film by bombarding it with positive ions moving at high velocities, and in this way the true nature of this bombardment can be determined.

#### CONTROLLING ELECTRON CURRENTS IN HIGH VACUUM

Most of the applications of high-vacuum tubes have depended upon the control of electron currents, as for example, by the grid in the three-electrode tube. The action of the grid is due to the charge on the grid modifying the space charge effect. This is the action that is employed in practically all tubes used today for radio transmission and receiving. There are many other methods, however, of controlling electron currents. A very important method is that used in the magnetron where there are only two electrodes in the evacuated space and the control is obtained by means of a magnetic field generated by an external coil of wire. A still simpler form of magnetron, suitable particularly to very large power tubes, consists of a very large filament in the axis of a cylindrical anode with very large, straight filaments. The magnetic field produced by the current through the filament is enough to prevent electrons flowing between cathode and anode.

Another form of tube by which electron currents can be controlled is the dynatron. This depends upon subjecting one of the three electrodes in the tube to electron bombardment in such a way as to cause electrons to be splashed out of it.

# Performance Characteristics of Autovalve Lightning Arresters

## Maintenance Reduction and Bettered Performance Are Claims for New Non-Chemical Protective Apparatus Suitable for All Applications—Principle and Basis of Design Described

By A. L. ATHERTON
*Supply Engineering Department, Westinghouse Electric & Manufacturing Company*

THE insulation of apparatus connected to any electrical system is subjected to surge voltages in some degree. Experience in the design of apparatus has led to the adoption of factors of safety which are sufficient to prevent apparatus failure under ordinary service conditions, but it has been found impossible or uneconomical to provide in this way for surge conditions. A benefit will be derived from the use of lightning arresters in all cases, but the need for lightning arresters varies over a wide range with the variation in surge conditions and condition of the apparatus.

The final criterion of lightning-arrester application is economic. The protection must pay for itself in savings to apparatus and service. The wide variety in service conditions, the difficulty in getting an accurate measure of arrester performance and the economic urge toward lower and lower costs has brought about the development of various protective devices covering a wide range in cost and in performance characteristics.

Judgment on any lightning-arrester problem, design, application or selection requires an understanding of the factors which make up both sides of the economic ledger account. On one side of this account is the saving which can be credited to the arrester—that is, the difference between the damage to apparatus and service which would result if the system were unprotected and the similar damage with the proposed arrester. On the other side of the account is the initial and maintenance cost. The damage to an unprotected system depends on local conditions, varies over a wide range and can be estimated only from experience and with engineering judgment. This factor is largely empirical and can ordinarily be determined only by experience on the system in question or on similar systems in similar localities. The damage to be expected with any particular type of arrester depends first on the local conditions which control the damage to an unprotected system and then on the characteristics of the proposed arrester. For an evaluation of this factor it is necessary to have a knowledge of the laws governing the phenomena of surges and of the principles of lightning arrester performance. These laws and principles are known with comparative accuracy. Initial and maintenance cost, on the other side of the ledger account, of course depend on the design of the arrester. For all commercial types they are fairly well known.

### CHARACTERISTICS OF SURGES

For the purpose of lightning-arrester considerations, a surge is a transient overvoltage resulting from the release in a system of a quantity of electrical energy which is free to flow in the circuit controlled only by the inductance, capacity and resistance of the circuit. The circuit has electrostatic capacity between conductors and to ground, and the conductors have inductance. The surge energy resides in the static field of the condensers and in the magnetic field of the inductances. When the energy is released on the line, as by the release of a bound charge following a cloud discharge or by the discharge of the magnetic field of apparatus in switching, a portion of the circuit is raised in potential above that of the adjacent circuit and current flows from the higher to the lower potential section through the distributed inductance of the conductors and charging the distributed capacity of the circuit into which it flows.

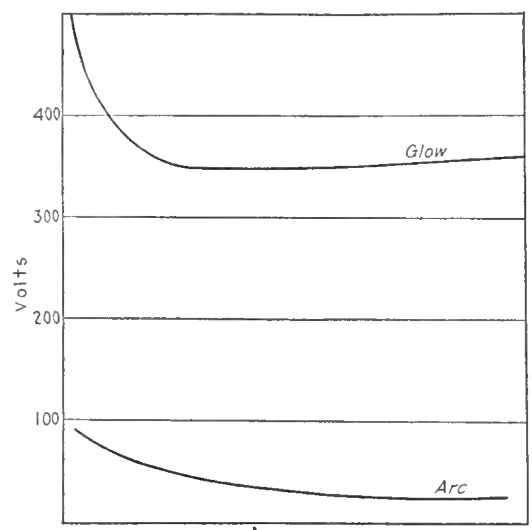

FIG. 1—VOLT-AMPERE CHARACTERISTICS OF ARC AND SLOW DISCHARGE

It has been shown that the relation of the current and voltage in surges is given by the equation

$$E = iZ = i\sqrt{L/C},$$

where

$E$ = the surge voltage,
$i$ = the surge current,
$Z = \sqrt{L/C}$ = the surge impedance,
$L$ = the inductance per unit length of the line,
$C$ = the capacity per unit length of the line.

This relation is of great value since it affords a means to a quantitative conception of the phenomena of the flow of surge current and makes possible the calculation of the division of current and the resulting voltages at branches in the circuit and at points where

the surge impedance is changed. For instance, it makes possible the calculation of the reduction in surge voltage resulting from the use of a lightning arrester of known characteristics.

It has also been shown that the propagation of a surge in a system is approximately at the speed of light; that is, 183,000 miles per second.

### Danger of High Voltages and Steep Wave Fronts

The outstanding characteristics of surges are high voltages and steep wave fronts—the first because this is the major cause of the danger to insulation, and the second because it has considerable bearing on the characteristics which it is necessary to give to a lightning arrester for good performance. While definite data are not available as to the maximum surge voltage which may be impressed on a system, there are indications that surges of external or atmospheric origin may have voltages as high as several hundred thousand volts, and surges of internal origin due to switching may have values of several times the line voltage. The steepness of the wave front is also variable over a wide range. In the case of a surge which travels on the line for a considerable distance, the wave front may correspond to a frequency of less than 100,000, while in the case of a surge which originates at the apparatus, as by the release of a bound charge from a cloud directly over the point in question on the line, the wave front may virtually be infinitely steep.

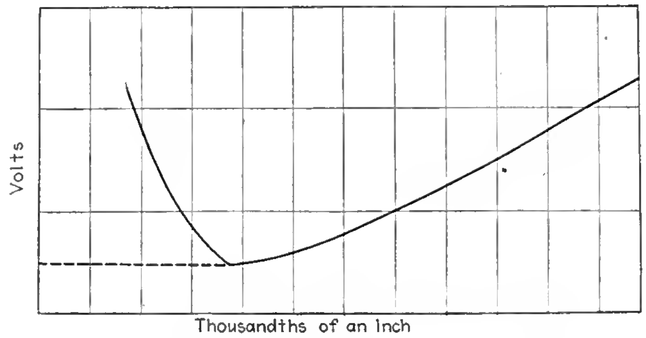

FIG. 2—BREAKDOWN VOLTAGE OF SMALL GAP IN AIR

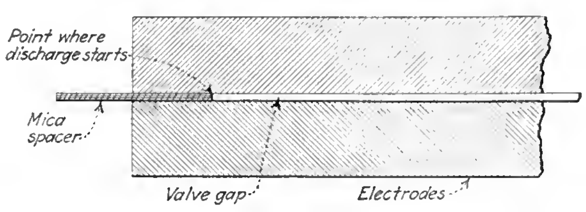

FIG. 3—ENLARGED VIEW OF AUTOVALVE ELECTRODES, SPACE AND VALVE GAP

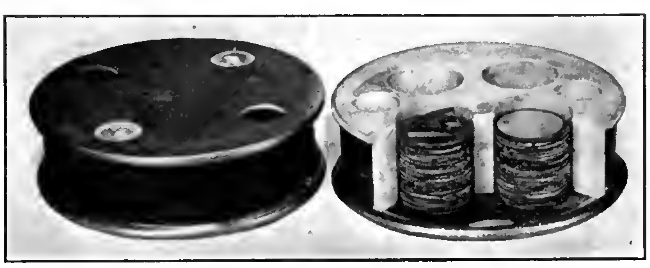

FIG. 4—PROPOSED 3,000-VOLT LARGE-CAPACITY UNIT

Very little is known quantitatively in regard to the effect of surge voltage on insulation. This is because the duration of these overvoltages is extremely short and the magnitude very great, which makes direct investigation difficult, and also because the chief attention of investigators of insulation problems has been given to study of performance under normal service conditions rather than under the abnormal conditions imposed by surges. It is probably a fact, however, that the damage which is done varies as some power of the voltage applied, possibly as the square, and that it varies directly with the time of application.

### Requirements for Lightning-Arrester Characteristics

A lightning arrester is a device which is inoperative under normal conditions, but which when a surge voltage appears should function to hold the surge voltage down to a value which will be safe for the insulation of the apparatus being protected. In order to do this, the requirements are:

1. The initial relief voltage, or the breakdown voltage, of the arrester must be at a safe value.
2. The discharge resistance, or the impedance of the arrester, to the flow of surge current must be low, so that the surge voltage will be reduced to a safe value. After the breakdown occurs the voltage across the arrester, and therefore across the apparatus being protected, is reduced from its original value in the ratio of arrester resistance to the sum of arrester resistance and surge impedance; that is:

$$E_1 = ER/(R+Z),$$

where
$E_1$ = the voltage on the arrester and apparatus,
$E$ = the original surge voltage,
$R$ = the arrester resistance,
$Z$ = the surge impedance.

The value of a low resistance is made apparent by this relation.

3. The arrester must be always ready to perform.
4. The performance must be such that no system disturbances or other troubles are introduced by the operation.
5. Economic limitations must not be exceeded.

### Discussion of Types

Efforts have continuously been exerted to develop a lightning arrester which would meet these requirements in the greatest possible degree, and these efforts have resulted in the development of the electrolytic arrester in its present form. This device is the standard lightning arrester for application where the maximum degree of protection is required. The first four of the requirements listed above are met by this device.

The breakdown voltage under surge conditions is only slightly higher than line voltage. This factor depends not only on the normal or 60-cycle breakdown, which naturally must be made higher than the line voltage, but also, because of the steep wave front of surges, it depends on the speed of breakdown, or, in other words, on the impulse ratio. The normal breakdown is made just enough above the maximum value of line voltage to prevent operation of the arrester due to line-voltage fluctuations. The speed is high—in fact, in the most highly developed form the impulse ratio is less than one; that is, the breakdown on steep wave front occurs at a voltage lower than the normal breakdown value.

The impedance to flow of surge current is extremely low. The only resistance is that of the electrolyte, the

circuit through which is very short and of large area. It is possible to make this type of arrester of such low resistance because no flow of power current is permitted. The characteristic of performance is such that practically no current flows at any voltage below a critical value and that at voltages greater than the critical value the current is proportional to the excess voltage. Thus when the normal conditions are restored the current is immediately reduced to zero and there is no "follow" of power current. Arresters without this "valve characteristic" cannot practicably be made with the very low resistance of the electrolytic, since they would pass large power currents, cause severe disturbances in the system, and since it would be impossible to provide for breaking the power arc in the series gap. With the valve characteristics these complications are all eliminated.

The third and fourth requirements are completely met. In some of the early forms of the electrolytic arrester trouble was experienced due to disturbances on the system set up by the charging operation, but the introduction of charging resistors eliminated this difficulty.

Unfortunately, however, the initial and maintenance cost are high enough to limit the application of electrolytic arresters to the protection of the more valuable or important apparatus. Moreover, the requirement for comparatively frequent attendance prevents their application in unattended installations.

Thus a large field of application cannot be taken care of by electrolytic arresters. Distribution transformers, ordinarily as much exposed to surges as any apparatus, for the most part do not economically warrant the use of arresters of such high cost, and it is practically never feasible to provide for the necessary frequent attendance. The growing use of unattended small substations and of the larger automatic substations introduces another large field where the use of electrolytic arresters is often not justified.

From the standpoint of service requirements, these applications require the same degree of protection as the larger attended equipments; but there has thus far been available no principle of operation which would provide the necessary valve type, or high-quality, arresters and at the same time be sufficiently flexible in design to meet the wide range of requirements of the various applications on the proper economic basis. There has been need for the development of a valve-type arrester based on a principle which is suited by flexibility to universal application and which will be of low initial cost, low maintenance expense, and will require, at the most, infrequent inspections. Such a device is provided in the autovalve arresters.

## Principle and Design Basis of Autovalve Arresters

The autovalve lightning arrester is essentially a spark-gap type of arrester to which the practically essential valve characteristic has been imparted by proper design of gaps and electrodes. To have valve characteristics spark gaps must have a breakdown voltage equal to the voltage while the current is flowing. The voltage across an arc in air is as shown in Fig. 1, in the lower curve. When the electrodes are kept cool the discharge is no longer an arc, but becomes a glow discharge with volt-ampere characteristics, as shown in Fig. 1, the upper curve. The breakdown voltage of a gap in air is as shown in Fig. 2. Obviously, if gaps can be made which break down at the minimum point, 350 volts, and which maintain the discharge as a glow, the conditions for valve characteristics are fulfilled, for with such gaps current will start to flow at 350 volts per gap, will be proportional to the excess of voltage over this value and will cease flowing when the voltage is reduced to this value. Such gaps are used in the autovalve arresters.

The minimum breakdown voltage is secured by using electrodes separated by thin mica spacers, as shown in Fig. 3. With such gaps breakdown occurs at the edges of the spacers at a voltage far lower than would be required for the gap itself, as is well known. When the mica is made of the correct thickness, this breakdown voltage remains approximately at the minimum valve of 350. The discharge is maintained as a glow by the use of electrodes of moderately high resistivity. The high resistivity prevents concentration of the discharge and thus keeps the energy distributed over the surface of the disk, preventing local heating and thus preventing the formation of arcs.

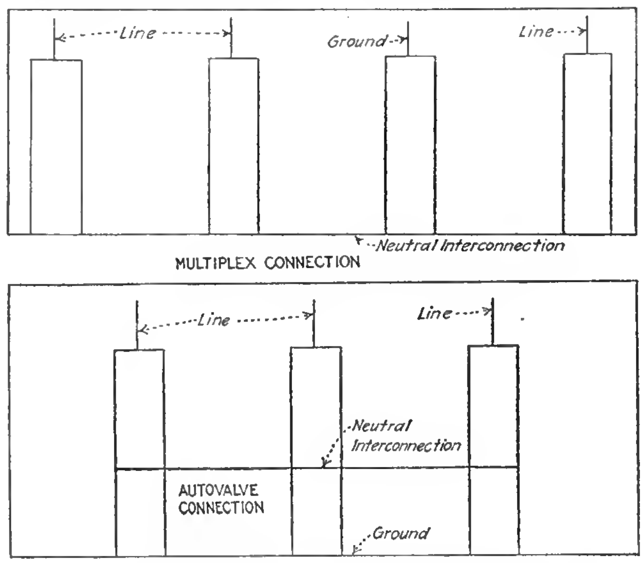

FIG. 5—AUTOVALVE AND MULTIPLEX CONNECTIONS FOR THREE-PHASE ARRESTERS

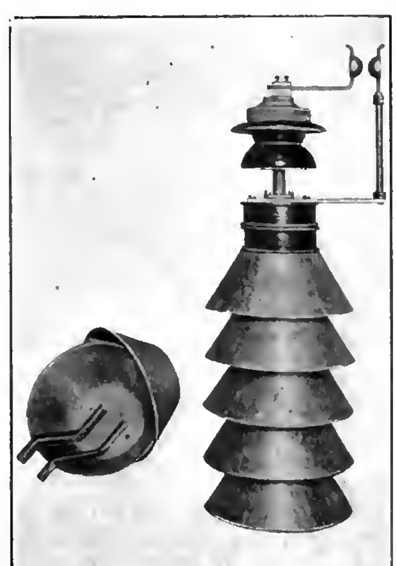

FIG. 6—PHASE LEG OF 37-KV., THREE-PHASE LARGE-CAPACITY ARRESTER

In the commercial form an autovalve arrester consists essentially of a column of disks and spacers forming a series of valve gaps, the number being proportioned to the line voltage and the area of the disk electrodes being such as to give the arrester the required resistance. Such a column in a proper casing is connected between line and ground through a series gap.

The number of valve gaps for any particular voltage is clearly indicated. In order to prevent the flow of power current, the line-voltage peak value must be less than the critical or counter voltage of the arrester—350 times the number of valve gaps.

The required resistance is not so clearly indicated because of the uncertainty in the maximum value of surge voltage which may be anticipated and because of the lack of complete information as to permissible surge voltages for standard or commercial insulation. In the design of these arresters, however, dependence has been placed on the years of experience with electrolytic arresters which have established that these arresters have performance characteristics which meet the service requirements. The area of the electrodes in the autovalve arrester has been selected to give a discharge resistance not greater than that of the standard electrolytic arrester.

Arresters of large capacity are made up of 3,000-volt units, each of which consists of four columns of

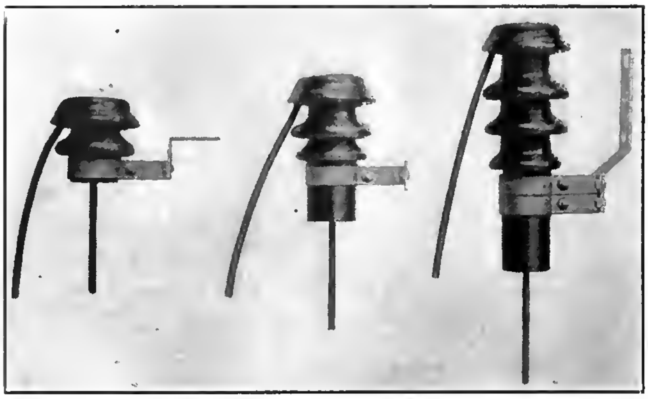

FIG. 7—DISTRIBUTION SIZES OF AUTOVALVE ARRESTERS

Three sizes of the line are shown with various forms of mounting bracket. The illustrated sizes are for 2,500, 7,500 and 15,000 volts.

disks 2 in. in diameter inclosed in a single porcelain case and held in place by metal ends spun over beads at the ends of the porcelain. These units are used in series to build up the phase legs of the large arresters for the protection of important apparatus in generating stations or substations. A single-phase leg of such an assembly for 37 kv. is shown in Fig. 6. In place of the familiar multiplex connection, using four columns each for phase voltage, three columns are used, each for line voltage. The two connections are schematically shown in Fig. 5. With the multiplex connection, the heavy surges of atmospheric origin pass through the three line elements in parallel and then all pass through the ground element. The voltage built up by the $iR$ drop in the arrester resistance of the line and ground elements in series is thus four times that across a line element. With the autovalve connection this is reduced, since each element carries current from one line only. In the developed form there results a reduction of the equivalent resistance of the arrester to 43 per cent of that of the same arrester except with the multiplex connection.

Arresters such as are shown in Fig. 6 parallel the commercial forms of electrolytic arresters very closely in performance characteristics. The critical voltage or voltage maintained across the valve gaps while current is flowing is approximately 25 per cent above the peak value of maximum rated line voltage. This margin of 25 per cent is the only point of appreciable magnitude in which the performance characteristics differ. With the electrolytic arrester the critical voltage is determined by the voltage applied in charging and is equal to the peak value of the voltage thus applied. The 25 per cent margin of safety is justified, since it is relatively unimportant from the standpoint of protection and since it eliminates the possibility of the flow of power current due to extreme line-voltage fluctuations.

The initial relief voltage is only slightly higher than the critical voltage. As has been stated, the normal breakdown voltage is approximately 350 volts per gap and thus approximately equal to the critical voltage. The speed is very high, since the great time lag required for puncture of solid insulation is not present because the breakdown occurs in air only. The time lag is so small that only the most refined testing procedures have sufficed to measure it.

The discharge resistance is determined by the resistivity, thickness and area of the disks. The resistance is chosen to insure glow discharge and thus prevent the formation of arcs. The thickness is chosen for proper mechanical strength. With these two factors known, the area required to give a discharge resistance equal to that of the electrolytic is readily calculated and obtained. This disk area, with a factor of safety, is used.

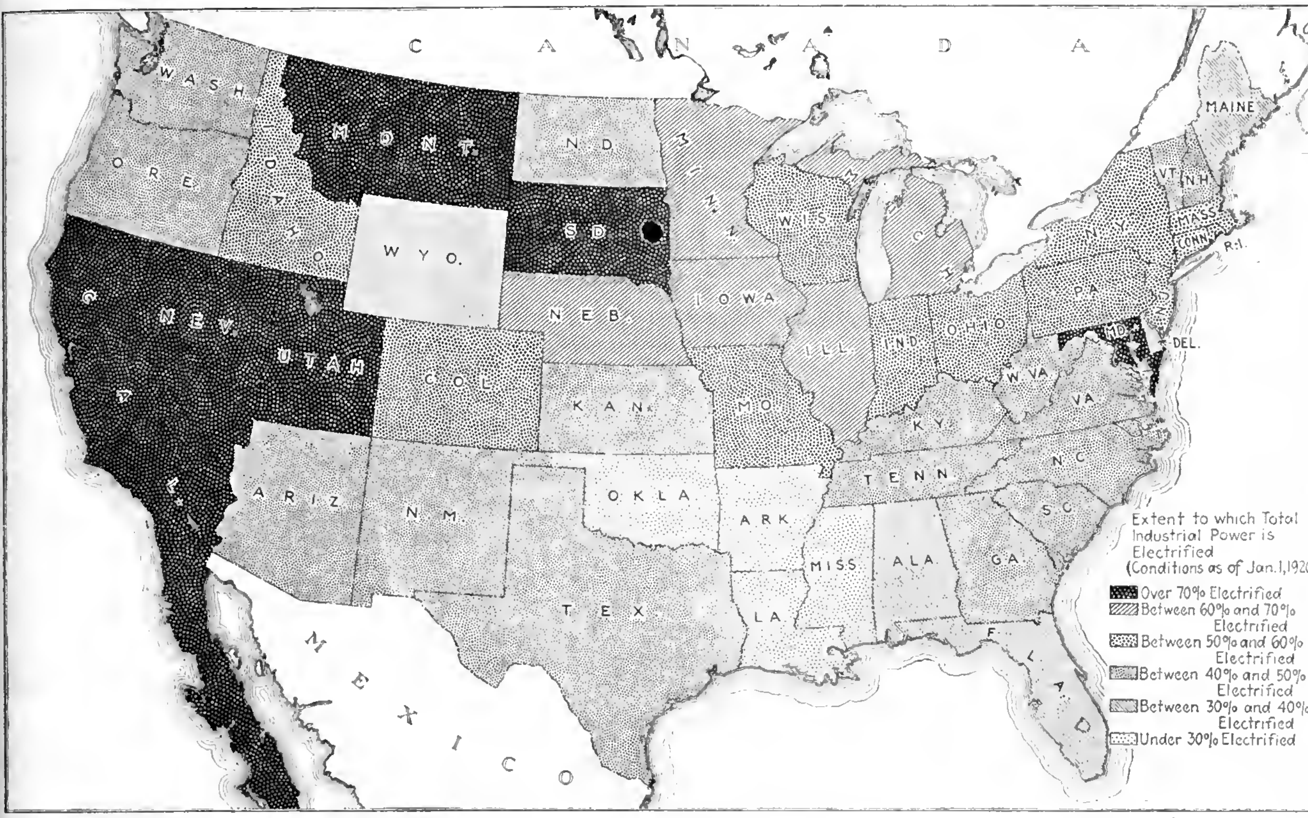
For use in applications where the expense of the large-capacity arresters is not justified, and particularly on distribution systems where arresters are installed close together so that more than one operates on any surge, a line of arresters of reduced area is provided. Three sizes, for 2,500, 7,500 and 15,000 volts, of this type "LV" line are shown in Fig. 7. In these arresters the design basis is the same as in the units of larger capacity except that a single column of disks is used. The performance is thus the same for the two types except that the discharge resistance is four times as great for the type "LV" as for the proposed large-capacity arrester.

Extensive laboratory tests over a period of two years and observation of more than 500 trial installations for periods ranging from nine to eighteen months have verified the theoretical basis both as to performance and as to durability.

The introduction of this principle of lightning-arrester construction marks a step of great importance in the control of apparatus failures due to surge voltages. Since valve-type arresters, suitable for use unattended and of any desired performance characteristics, can now be made within the economic limitations, it becomes feasible to provide adequate protection for apparatus of all classes and sizes under all conditions of installation.

## Tests of Thermocouples

TESTS of the pure platinum and platinum-rhodium wire prepared at the Bureau of Standards for thermocouples have been carried out by the heat division. These tests are the same as those applied to commercial couples, which were recently reported by Fairchild & Schmidt in *Chemical and Metallurgical Engineering*. Results so far obtained are said to show that couples of material purified, melted and drawn to wire at the bureau are appreciably superior to the best commercial couples previously tested. Papers covering these subjects will be presented at the spring meeting of the American Electrochemical Society.



# Rapid Growth of Industrial Load

## Central-Station Motor-Connected Business Totaled 19,561,200 Hp. on Jan. 1, 1922—Pennsylvania Leads All Other States—Industry in the Aggregate About 61 per Cent Electrified at Present Time

THE growth of the central-station motor-connected load is one of the most remarkable facts pertaining to that industry of unusual achievements. Prior to 1907, only sixteen years ago, the lighting customers consumed more electrical energy than the industrial power customers, but since that date the total energy consumption by industrial consumers has increased by about 953 per cent, while the total energy consumed by the lighting customers has increased by only about 320 per cent. The electrical energy consumed by industrial power customers during 1922 was approximately 23,000,000,000 kw.-hr., while the lighting requirements probably did not exceed 8,000,000,000 kw.-hr.

The extent to which the motor-connected load has been cultivated by the central-station companies during the last eight years is clearly indicated by a survey recently completed by the ELECTRICAL WORLD. Returns received from about 70 per cent of the electric light and power industry indicate that subsequent to 1914 the connected motor load has almost tripled, totaling 19,561,200 hp. on Jan. 1, 1922. During this period the number of motors served has grown from 719,800 to 1,759,300, an increase of about 144 per cent. Details of this growth will be found in the tabulation on page 400.

A study of the data issued by the United States Census Bureau indicates that in 1920 there were 520,400 motors run by energy generated in private plants and that the rating of these motors totaled 8,228,800 hp. Adding these figures to those for central stations gives a total of about 2,300,000 electric motors installed on Jan. 1, 1922, with a total rating of about 28,000,000 hp. Further studies based on the census data indicate that in 1920 there was a total of 20,294,400 of industrial horsepower which had not been electrified, and that approximately 1,796,400 additional motors would be required to electrify fully all the industries of the country. A comparison of related figures indicates, therefore, that in 1920 the total industrial power of the country was only about 54.1 per cent electrified. It is estimated this figure has increased to about 61 per cent.

The central stations of the East North-Central States reported the largest motor-connected load on Jan. 1, 1922, with 5,251,300 hp. and a total of 530,900 motors. The Middle Atlantic States, another intensely industrial section, followed with 4,744,000 hp. and 429,300 motors. A study of the motors served by energy generated in private plants, however, indicates that the central stations in the Middle Atlantic States have a more fruitful field for increasing their motor-connected load through the gradual elimination of the private generating plants.

It appears that in 1920 California led all other states in the electrification of its industries. The reports indicate that 80.4 per cent of the industrial power of that state was electrified. Other states reporting a high percentage of industrial electrification are Utah with 76.8 per cent, Nevada with 72.2 per cent, Maryland with 70.5 per cent and Montana with 70.4 per cent.

## Central-Station Motor-Connected Load and Degree of Electrification of Various States, 1915-1922

# Facts on the Value of Wholesale Business

## The High Points of an Analysis of the Profitableness of Orders, Lines of Merchandise and Individual Customers, Based on the Experience of the Largest Electrical Jobber

By O. D. STREET

MANUFACTURING accounting is a highly developed art. This is because manufacturing accounting has received for the past half century an increasing amount of scientific attention. However, in the field of distribution, there is probably not a firm in the country which knows what it costs to sell any one of its articles, unless it sells only one article, nor a firm which knows what it is costing to sell to any one of its individual customers.

MR. STREET, who has recently become vice-president of the McGraw-Hill Company, was for ten years general manager of distribution of the Western Electric Company, in executive charge of its great system of fifty electrical supply jobbing houses. Through this period the business of these many branches has been analyzed and classified in deliberate, systematic effort to develop a sufficient volume of dependable statistics to make it possible to determine what has been the matter with the electrical jobbing business, by finding out what kind of orders, what kind of merchandise and what kind of customers are profitable and why. What these findings have been Mr. Street has briefly pictured in this article, which was presented as a paper before the Association of National Advertisers, just prior to his resignation.

Approximately ten years ago the Western Electric Company came to recognize how incomplete its knowledge was as to how it made even the little money which was then made in its jobbing business. We could not get away from the thought that there must be something, or several things, fundamentally unsound in our program—that there must be leaks somewhere, or that we were unconsciously pulling against some unseen resistance.

Analytical work was started. Clerks were put to work studying the cost copies for a period of twelve months on the number of orders received where the value was less than $5. Similar data were obtained at the same time on orders where the value was from $5 to $10, $10 to $25 and over $25. Table I is a summary of the results of such a study. These figures proved that we were losing money, and a pile of it, in connection with at least 60 per cent of our transactions—the small orders which carried the highest rate of profit.

A further analysis of the details of our expenses showed us that a great many of these expenses varied directly with the number of orders handled. A continuation of our studies along this line brought us to the point where we found we could closely approximate our costs in dollars and cents for handling the different size orders. Table II shows the result of one of these studies. This indicated that our expense on small orders—those where the value was less than $25—varied from $3.25 to $5, while the average gross profit on these orders averaged from $0.71 to $4.48. The average amount of loss on these orders was about $1.63, and as such orders represented about 60 per cent of all of our orders, the aggregate loss was found to be very large—close to three-quarters of a million dollars annually.

It is seen, therefore, that there were two major advantages derived from this particular line of investigation:

1. We discovered, contrary to our belief, that the orders which carried the highest rate of profit were in reality the ones on which, taken as a class, we were losing an enormous amount of money.

2. We discovered, again contrary to our belief, that the orders which carried the lowest rate of profit were in reality the ones on which, taken as a class, we made all our money.

### PROFITABLENESS OF LINES OF MERCHANDISE

Having determined to our satisfaction the kind of orders on which we made money and the kind on which we lost money, we began to study lines of merchandise in order to see what we could learn in that direction.

Prior to the time of these studies and because we did not know of a more accurate method of approximating our costs, we, like other distributors, were accustomed to estimate the profitableness of our business by lines of merchandise by comparing the gross profit rate earned on each line with the average expense rate realized on the entire business. In computing the percentage of net profit earned on investment, consideration, of course, was given to a low investment, such as would result from consigned stock, direct shipments and prompt payments, but, in the main, the amount of net profit was determined by taking the difference between the gross profit rate on the line and our average expense rate and multiplying the sales of the line thereby.

But the studies above referred to had proved conclusively that such a method of computing costs was most misleading. We now know that just because our average expense rate is 15 per cent it does not follow

TABLE I—ANALYSIS OF ORDERS HANDLED

| Value of Orders | Number of Orders | Per Cent of Total | Total Value | Per Cent of Total Value | Average Value per Order | Amount Gross Profit | Per Cent of Total Profit | Gross Profit Rate | Average Gross Profit per Order |
|---|---|---|---|---|---|---|---|---|---|
| Under $5 | 193,000 | 25 | $463,200 | 1.0 | $2.40 | $137,030 | 1.6 | 30 | $0.71 |
| $5 to $10 | 108,000 | 14 | 783,000 | 1.7 | 7.25 | 223,560 | 2.6 | 29 | 2.07 |
| $10 to $25 | 162,000 | 21 | 2,783,160 | 6.0 | 17.18 | 725,760 | 8 3 | 26 | 4.48 |
| Total above classes | 463,000 | 60 | $4,029,360 | 8.7 | $8 70 | $1,086,350 | 12.5 | 27 | $2.35 |
| Over $25 | 309,000 | 40 | 42,577,800 | 91.3 | 137.80 | 7,630,200 | 87.5 | 18 | 24.70 |

TABLE II—RELATIVE PROFITABLENESS OF ORDERS HANDLED

| Size of Order | Annual No. of Orders Handled | Average Value per Order | Average Gross Profit Rate, per Cent | Average Gross Profit per Order | Average Expense per Order | Average Net per Order | Total Net |
|---|---|---|---|---|---|---|---|
| Under $5...... | 193,000 | $2.40 | 30 | $0.71 | $3.25 | —$2.54 | —$490,220 |
| $5 to $10...... | 108,000 | 1.25 | 29 | 2.07 | 3.74 | —1.67 | —180,360 |
| $10 to $25..... | 162,000 | 17.18 | 26 | 4.48 | 5.00 | —0.52 | —84,240 |
| Total above classes..... | 463,000 | $8.70 | 27 | $2.35 | $3.98 | —$1.63 | —$754,820 |
| Over $25...... | 309,000 | 37 80 | 18 | 24.70 | 14.58 | 10.12 | 3,124,500 |

that our expense rate on all our items, or on all our lines, or on all our orders, is 15 per cent. This 15 per cent is an average, and, being an average, it means that the expense rates on some orders are higher than 15 per cent and on some lower than 15 per cent.

By discovering and introducing this cost-per-order factor we had provided a gage whereby we could the more closely compute our costs on orders and on lines of merchandise. One of the more conspicuous instances where we changed our sales practice as a result of the application of this new method of computing costs was in connection with a certain line of merchandise on which we had always thought that we had made little if any money. Our average expense rate at this time was about 15 per cent, and in computing net profits on this line an estimated expense rate of 13.5 per cent was applied. As the gross profit rate that year on the line was 12.5 per cent, we figured that we had lost 1 per cent on sales and about 15 per cent on the investment. But in one of our studies we had found that the average value of our orders on this line was about $70, while the average value per order on all our business was at that time only $30 and the average expense per order was $4.50. This was before the war.

Since the average value of the orders on this line was $70, and since we had applied an expense rate of 13.5 per cent against the line, it was the same as saying that the cost per order for handling the line was $9.45 ($70 × 13.5 per cent) as compared with an average expense of but $4.50 per order on all our business. It must be remembered that our average order, the distributing cost on which was $4.50, contained two and one-half items, but here we were assessing $9.45 worth of expense against one item—more than twice as much money as it cost to handle the average two-and-a-half-item order.

After considering the expense from this angle, we concluded that our average expense of handling that line which was on consignment and on which we had no abnormal sales expense and did no advertising did not cost at the outside any more money per order than did our average order. Thereafter we applied 6.5 per cent as the expense rate applicable to our sales on this line, and since our gross profit rate has been averaging about 15 per cent on the item, we have been showing during the past few years a net profit of about 8.5 per cent on sales, instead of a loss, as had been our previous practice. Eight and one-half per cent net on sales indicates, as you can imagine, a handsome net return on the investment.

On still another line we had been showing a profit on sales of 15 per cent and a profit on investment of 38 per cent, but now on that same item, the gross profit rate being about the same as before, we are showing a loss on sales of about 2.5 per cent and a loss on investment of about 8 per cent. This was one of the items we had been pushing hard, because since the gross profit rate was 30 per cent we had thought we were making a great deal of money on it; but instead our new system of computing expenses proved that we were really losing money on every sale.

### Gross Profit No Guide

In years gone by we, in common with other distributors, had been possessed with the idea that the only way to increase the net profit earned on our investment was to increase our rate of gross profit. Now we have come to see that there is vastly more money in some business taken at a low rate of gross profit than there is in other business taken at an appreciably higher rate. We see now that a gross profit rate means nothing until we know to what amount that rate is going to be applied.

As is seen by referring to Table III, since our average expense per order is about $7, we cannot make money if our orders average a value of $30, even if our gross profit rate be 20 per cent, for this would give us an average profit of but $6 per order. As our expense is $7, we should be losing $1 on every order. On the other hand, if the value of our average order is $45 and the average profit rate 18 per cent, resulting in a gross profit per order of $8.10, we shall make some

TABLE III—ANALYSIS OF TOTAL SALES BY MONTHS

| | Net Sales | Gross Profits | Gross Profit Rate | Expenses | Net Profit | No. of Orders | Average Value per Order | Average Gross Profit per Order | Average Expense per Order | Average Net Profit per Order | Per Cent Earned on Investment |
|---|---|---|---|---|---|---|---|---|---|---|---|
| January................ | | | 19.1 | | | 50,912 | $46.85 | $8.93 | $7.65 | | |

| June.................... | | | 18.4 | | | 60,756 | 51.45 | 9.49 | 6.71 | | |
| Average for the second quarter............. | $3,013,000 | $550,000 | 18.2 | $413,000 | $137,000 | 60,254 | $50.00 | $9.13 | $6.84 | $2.29 | 19.7 |
| July.................... | | | 17.1 | | | 62,620 | 54.38 | 9.30 | 6 94 | | |
| August.................. | | | 17.7 | | | 64,303 | 56.66 | 10.03 | 6.86 | | |
| September.............. | | | 17.1 | | | 65,424 | 60.54 | 10.40 | 6.96 | | |
| Average for the third quarter............. | $3,673,000 | $635,000 | 17.3 | $443,000 | $192,000 | 64,116 | $57.30 | $9.92 | $6.91 | $3.01 | 26.9 |
| October................ | | | 17.0 | | | 76,992 | 62.00 | 10.50 | 6.90 | | |
| November.............. | | | 16.4 | | | 72,886 | 64.30 | 10.50 | 7.16 | | |
| December................ | | | 16.4 | | | 92,302 | 66.83 | 10.95 | 7 67 | | |
| Average for the fourth quarter............. | $5,207,000 | $862,000 | 16.6 | $587,000 | $275,000 | 80,727 | $64.50 | $10.68 | $7.27 | $3.41 | 33.8 |

money, and we shall make even more if the average value is $60 and the average profit rate 17 per cent, since that would give us an average gross profit per order of $10.20 against an average expense of $7.

Small orders, the more so where they are 60 per cent of all orders, tend to lower the average profit per order below $7. The large orders are the only ones which help to raise the average profit, and only by raising the average profit per order well above the average cost per order can we hope to make a good return on the investment. With us, under ordinary conditions of investment, the average amount of gross profit per order must be from $2.50 to $3 greater than the average cost per order in order to show a return of 25 per cent on the investment. This can be figured out by assuming a given condition where the average value per order is $56, the average profit rate is 18 per cent, the average amount of profit per order is $10, the average expense per order is $7, the average number of days receivable is 50 and the average investment in merchandise is $4. Our formula would then work out as follows:

$$\frac{G-E}{M+R}=\frac{\$10.00-\$7.00}{\$\ 4.00+\$8.00}=\frac{\$\ 3.00}{\$12.00}=25 \text{ per cent.}$$

### Cost per Order Constant

To comprehend thoroughly, you must see the line of reasoning followed in reaching the conclusion that our expenses per order tend to be relatively constant. Our expense per order is about 70 per cent higher than it was before the war, but the expense has gone up proportionately at all houses and most likely among all distributors. This increase is the result of the higher cost of labor, trucking, rent, etc. If these factors go higher, our average cost per order will be higher than at present. If they decrease, the average cost per order will decrease.

At our Salt Lake house, where the organization is small, the cost per order is $6, and only at one or two of our fifty houses, where certain known abnormal expenses prevail, have we a cost in excess of $7.50 per order.

With us the expense per order is relatively constant month by month at each house, month by month at all houses. This is because the expenses of such a distributing organization tend more closely to follow transactions than to follow sales value. This point is made more clear by the figures in Table IV.

You see that Chicago handles ten times as many orders as Salt Lake, and that the average value of the order at Chicago is twice as large; yet the average expense per order at Chicago is but $7.61 and only $1.61 more than the average expense at Salt Lake. If expenses followed values, and since the average value of Chicago's order is exactly twice as large as the average value of Salt Lake's order, Chicago's expense per order would be twice as large as at Salt Lake, or $12 instead of $7.61. For the past eight years the number of orders handled at each of the houses, and for the company as a whole, has not varied from one year to

TABLE IV—DATA FOR CHICAGO AND SALT LAKE FOR TWELVE MONTHS

| | Number Orders Handled | Average Value per Order | Average Expense per Order | Average Expense Rate |
|---|---|---|---|---|
| Chicago | 131,000 | $76.00 | $7.61 | 10.0% |
| Salt Lake | 13,000 | 38.00 | 6.00 | 15.5% |
| Per cent difference | +900 | +100 | +27 | —35 |

the next to any appreciable extent, and we do not expect that this condition will change. (See Table V.)

While I have been emphasizing the fact that our average expense per order tends to be quite constant, I have not forgotten that we may still have too many employees at some of our houses and that the work of others is not as efficient as it might be. In other words, there is a chance at every point to do a more efficient, hence a cheaper, job. On the other hand, we recognize that with our office and warehouse work more or less standardized as it is, and with the competent department heads we have in charge at the houses, no great amount of money is being wasted. Our general department specialists are finding it harder each year to develop new methods by which we can reduce expenses. To be sure, a couple of men, after working a month last year at one house, were able to point out where changes could be made that would effect savings amounting to $4,000 per annum. Now, $4,000 is worth saving, but even if saved it will reduce the expense at that house only to the extent of 10 cents an order, since the house handles 40,000 orders a year. It is right that we keep our expenses down, and we expect to continue searching for better and cheaper methods, but we think that it is much easier by applying the knowledge we now have to get our average profit per order up 50 cents than it is to get our average expense per order down 10 cents. Not only is it easier, but it is nearly five times as valuable from a net profit standpoint.

### Profitableness of Individual Customers

We have now considered how to test the profitableness of orders and the profitableness of lines, and how to watch the progress of the business as a whole; and there is one other thought which is worth considering. Let us see if by the use of these same methods we can get a better idea as to the profitableness of the individual customers, for, after all, it is the customer to whom we are trying to sell and whom we desire to serve.

Why is it that we have warehouses in fifty cities carrying in each several thousand items of merchandise? Why do we publish an expensive year book in which we indicate our ability to furnish no less than fifty thousand different items of merchandise? In short, for what purpose has this national sales organization of ours been created if not to seek out and serve customers in the expectation that the business relation thus established may prove profitable?

If it is the job of the distributor to endeavor to show a net profit on the business of each customer he serves, it is essential that we should have a gage whereby we

TABLE V—DATA OF NUMBER OF BILLS RENDERED

| | 1915 | 1916 | 1917 | 1918 | 1919 | 1920 | 1921 | Aver. 7 Years |
|---|---|---|---|---|---|---|---|---|
| Pittsburgh | 27,363 | 30,976 | 31,417 | 28,450 | 33,228 | 39,979 | 33,527 | 32,134 |
| Atlanta | 39,693 | 46,170 | 40,934 | 39,951 | 41,733 | 48,646 | 40,088 | 42,459 |
| Minneapolis | 37,763 | 41,262 | 37,115 | 33,213 | 35,741 | 47,418 | 41,486 | 39,143 |
| St. Louis | 34,614 | 41,180 | 36,845 | 34,952 | 39,584 | 43,596 | 35,258 | 38,004 |

| Total all houses | 700,459 | 800,653 | 752,605 | 705,407 | 788,572 | 913,835 | 757,922 | 774,208 |

can at least approximate the profitableness of a customer's account. A number of years ago we designed and sent to our houses a form to be used for this purpose, reproduced herewith in Table VI.

The very least we need to know is the annual sales, the average gross profit rate, the number of orders handled during the year and the average amount of profit per order. Above all, we must know the average amount of profit per order, for without those data we can tell nothing at all about an account from a net-profit standpoint. We may guess that it is good, but we are only guessing. An estimate based on fairly correct accounting principles is to be preferred.

Where we found that accounts were not being analyzed from a net-profit standpoint, some spot checks were made, along the line suggested by Table VI, and the results of some of these are cited below.

**Monthly Analysis of Individual Customer's Account**

| | Sales | Gross Profit Rate | Amount Gross Profit | No. of Orders Handled | Average Value per Order | Average Profit per Order | Average No. Days Receivable |
|---|---|---|---|---|---|---|---|
| January | | | | | | | |
| February | | | | | | | |
| March | | | | | | | |
| Average first quarter | | | | | | | |
| April | | | | | | | |
| May | | | | | | | |
| June | | | | | | | |
| Average second quarter | | | | | | | |
| July | | | | | | | |
| August | | | | | | | |
| September | | | | | | | |
| Average third quarter | | | | | | | |
| October | | | | | | | |
| November | | | | | | | |
| December | | | | | | | |
| Average fourth quarter | | | | | | | |
| Average twelve months | | | | | | | |

TABLE VI—FORM USED BY ALL BRANCHES IN ANALYZING CUSTOMER'S ACCOUNT

At one house we took an account of our sales, which were about $16,000 a year and the profit rate about 15 per cent. The sales manager expressed his belief that the account was profitable because, to use his argument, "the volume was large." After going to the books and counting the number of orders which had been rendered during the year, we found that the average profit per order produced by this sixteen-thousand-dollar account was $2.10. The average expense per order at that house was $6.50. The customer was being allowed 120 days in which to pay his bills, was receiving the benefit of our best prices, and the stores manager had stated that, from a service and claims standpoint, the customer was a "perfect pest," yet his unreasonable demands for special services were accorded, 120-day payments were allowed and best prices were quoted, because it was thought the account was profitable, and it was considered profitable simply "because the volume was large." When it was found that the average profit was but $2.10 per order, neither the sales manager nor any one else thought the account was profitable, and instantly steps were taken to change the situation, not by closing the account, but by changing the character of it.

At another house, where the average expense per order was $6.25, the two largest accounts on the books happened to be two central-station accounts. The purchases of one amounted to $60,000 that year at an 11 per cent rate of gross profit and those of the other to $58,000 at a 12 per cent rate. One was in the home city of the house and the other a hundred miles away. Asking the house concerned which was the more profitable account of the two, we were told that the one in the home city was the better. We counted the orders rendered during the year and found that the gross profit on the home city account averaged $6 per order and that on the other averaged $27 per order. You see, the management had guessed wrong, for there was no chance for a net profit in the home city account, while in all probability the other account, which produced $27 profit per order, was showing a return of better than 100 per cent on the investment. Bills in each case were being discounted and paid in ten days. It goes without saying that the home city account is now being studied so that it may be made a net profit earner as well as a volume builder, and the outside account is receiving more attention than ever before lest it should be lost. No house is going to take chances in losing so profitable an account after it once knows how profitable it is.

At another house, where the average expense per order was $7.50, several dealer accounts were analyzed. The volume in each case was large, the gross profit rate was good, and payments were prompt. The volume of sales and gross profit per order for twelve months on a few of these accounts are shown below:

| | Total Sales | Gross Profit Rate | Average Value per Order | Average Profit per Order |
|---|---|---|---|---|
| Account No 1 | $43,637 | 17% | $232 | $39.44 |
| Account No. 2 | 25,035 | 19% | 169 | 32.11 |
| Account No. 3 | 40,548 | 18% | 157 | 28.26 |
| Account No. 4 | 35,350 | 18% | 121 | 21.78 |
| Account No. 5 | 28,550 | 17% | 170 | 28.90 |

Since we know there were no abnormal expenses in connection with the business of these accounts, we were satisfied that they were good money makers for the house. It is all right to watch sales volume, but we must not fool ourselves by assuming that a large volume of sales made to a customer necessarily means that we are deriving any net profit from the account. Such an assumption is not warranted without further analysis.

If, as is generally assumed, new alignments are to be worked out in the producing and distributing fields, and since it is a certainty that the successful agencies in both of these branches five or ten years hence will be those whose efficiency is of the highest, perhaps you will agree with me that those of us who would be recorded among the survivors must hasten to ascertain where we now stand, in order that losses incurred in unproductive endeavor may be eliminated and that the money thus saved may be invested in productive endeavor.

When we know the production and the distribution cost of each thing we market, when we know the profitableness of the account of each jobber we serve, and when the jobbers and wholesalers know the profitableness of the account of each retailer they deal with, then, and not until then, will there be fewer factories in which the same thing is made, fewer distributors who vend these articles in the wholesale mart and fewer dealers who pretend to serve the buying public. Then, and not until then, shall we have solved the question as to why production and distribution costs are so high.

A Place Set Apart for Suggestions, Comments and Criticisms, to Which All Men of the Electrical Industry Are Cordially Invited to Contribute

## Value of Mathematical Studies in Engineering Education

*To the Editors of the* ELECTRICAL WORLD:

Current literature on electrical engineering subjects reveals a very marked and increasing interest on the part of prominent engineers in the education of engineering students. At a recent convention of the A.I.E.E. no less than five papers by leading engineers were devoted to this subject. The dominating idea of the discussion was the extreme importance of mathematics as the foundation upon which the superstructure of engineering must be built, it being even more important than physics and chemistry. The consensus of opinion also appeared to be that the majority of engineering graduates are very deficient in mathematics, especially in its application to engineering problems. To quote a very distinguished engineer on this subject: "Most of the graduates of the technical schools are woefully weak in mathematics."

The attention given by engineers to the teaching of mathematics in engineering colleges is intensely interesting in that it is obviously indicative of a change in the methods of handling engineering problems. It is one phase of the transition from the "cut-and-try" kind of engineering to what Mr. Lamme has so aptly termed "engineering by analysis" (B. G. Lamme, "Electrical Engineering Papers," page 755). The colleges are generally held responsible for the engineering graduate's lack of skill in applying mathematics to engineering problems, but are they altogether to blame for this condition?

Because of the prominence of the engineers who have voiced a demand for more thorough instruction in mathematics, it is readily inferred that this demand is a general one on the part of engineering executives. From the writer's experience he would judge, however, that this is far from being the case and that most executives still prefer to have their engineering problems solved by the "cut-and-try" method rather than by analysis. The main reason for this probably is that efforts put forth in experiments are more in evidence than when they are expended in analytical investigations.

In development of new apparatus many schemes will ordinarily be investigated and discarded before a really good one is discovered; that is, many investigations will of necessity lead to negative results. However, if the conclusions reached, even though unfavorable, have been arrived at through experiments, enough energy and enthusiasm has usually been displayed by the engineer to satisfy most executives. On the other hand, although the cost of obtaining the same negative results by analysis may be only a fraction of the cost of experiments, the executive is likely to conclude that the engineer has been doing nothing, unless he, himself, happens to have a clear grasp of the mathematical processes involved, which appears to be the exception rather than the rule.

An incident which came to the writer's attention about a year ago is a case in point. Monel metal was found to have the peculiar and interesting property of changing its magnetic reluctance at a temperature near the boiling point of water. It was discovered that a thin circular disk of this metal, mounted so as to rotate with little friction, could be made to revolve if one pole of a magnet was brought near the edge and heat applied to its surface a little distance from the point nearest the magnet pole.

Then, arguing from this fact, the brilliant idea was conceived of revolutionizing the design of energy-converting apparatus. At considerable expense a motor was constructed in which sections of the rotating element were to be alternately heated and cooled by air currents. An extremely simple calculation would show that the amount of energy which is required to make sufficient weight of the metal pass through the necessary temperature variations rapidly enough for even moderate speeds is so large that the efficiency of such a motor would approach the vanishing point. As reported to the writer, it did not even turn over when put on test.

Of course, this is an extreme case, and few executives would consider such a proposition seriously, but the point to be emphasized is that many of them as yet do not fully appreciate the value of "engineering by analysis." When the analytical side of engineering becomes recognized as a powerful tool of investigation and a general demand for engineers with more thorough knowledge of mathematics is created thereby, it is very probable that colleges will respond by turning out graduates better equipped to handle such problems than they are doing at present. K. L. HANSEN.

Milwaukee, Wis.

## Testing Polyphase-Type Watt-Hour Meters

*To the Editors of the* ELECTRICAL WORLD:

In reference to the letter of Prof. A. E. Knowlton published in the Jan. 13 issue of the ELECTRICAL WORLD (page 102) I would like to say that I appreciate criticism from such a high source and that this criticism is theoretically just. However, in connection with the practice of using resistance in the primary circuit of a phantom load in testing meters as described in an article on that subject in the Dec. 23 issue, I should like to say that there must have been some misunderstanding on the part of Professor Knowlton, or else the matter was not stated in a clear manner in the article.

In the plan outlined it might not have been clear that the resistance is not inserted in the primary to change the secondary current when differently sized meters are being tested, but only to compensate for the slight changes in the primary voltage due to fluctuations. The secondary current is regulated by the size of meter connected in the circuit and will automatically adjust itself to the required value due to the different and proportional resistances in the current coils of the variously sized meters, combined with that of the standard. In fact, this resistance in the primary is rarely ever changed, even when testing meters from 5 amp. to 50 amp., and consequently the power factor does not drop to an objectionable value and, by actual measurement, hardly ever below 90 per cent. Of course, this system is not recommended to calibrate rotating standards or to settle lawsuits. DAN C. HOFFMANN.

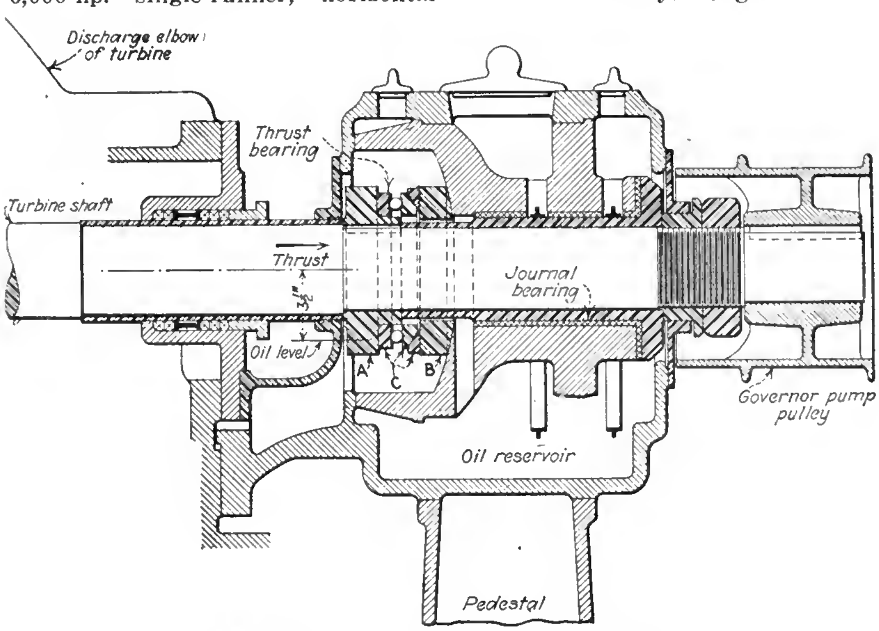
## Ball Thrust Bearing Solves Trouble Given by Disk-Type Bearing

TROUBLE with a disk thrust bearing led to the substitution of a ball thrust bearing by the Portland Railway, Light & Power Company. The former type of bearing had proved unsatisfactory in connection with the reconstruction of a 6,000-hp. single-runner, horizontal hydraulic turbine. Early in 1922 the company decided to reconstruct this turbine for a capacity of 8,200 hp., having been assured by the manufacturer that with a modern design of runner, new wicket gates and a larger discharge quarter-turn and draft tube this additional capacity could be gained at an improvement in efficiency of from 5 to 7 per cent.

The change in quarter-turn necessitated a new thrust bearing to take care of the unbalance due to there being but a single runner. As soon as the new equipment was installed and the waterwheel put into operation trouble developed immediately in the thrust bearing. The new bearing furnished for the reconstructed wheel was of a modern design, consisting of one rotating and one stationary disk with babbitted face and self-aligning seat. Six weeks' time was spent in refinishing and making adjustments of the disk bearing, with the result that at the end of that time no reason could be found for the bearing not functioning as intended. The waterwheel unit was needed very badly for peak-load purposes, and no suggestions or recommendations were offered by the manufacturer to solve the difficulty. Urgent need of the unit demanded positive action. The disk bearing was laid aside and attention turned to other types of thrust bearings. A ball thrust bearing was found in local stock, and decision was made to try it as a solution of the trouble. With slight modification, parts were machined for adapting the ball thrust bearing, and the unit was placed in operation. The parts for adapting the ball thrust bearing were made, and the bearing was installed and operating within two days after it was decided to make a trial of it. The machine has since been in operation for nearly three months at from partial to full load with no trouble whatever. The total thrust on the bearing varies from about 6,000 lb. at no load on the unit to zero at about three-quarters load, beyond which point the thrust is practically neutral.



ADAPTING BALL THRUST BEARING TO SINGLE-RUNNER, HORIZONTAL HYDRAULIC TURBINE SOLVES DIFFICULT BEARING PROBLEM

The accompanying illustration shows in cross-section the general arrangement of the thrust bearing. The parts furnished locally to adapt the ball thrust bearing are indicated by *A* and *B*. It will be seen that part *B* has a spherical self-aligning seat. The ball thrust bearing, which also has a self-aligning washer, is indicated by parts marked *C* between *A* and *B*.

## Running Cables on Racks Sometimes Dangerous

IN BUILDINGS where there are a number of heavy wires or cables it has been the custom to carry these cables on racks. This arrangement is really an adaptation, used indoors, of the plan, used outdoors, of carrying the wires open on arms on the poles. Outside, the carrying of very heavy feeder lines on the poles is more and more being done away with and cables in underground ducts are taking the place of the former open wiring.

In many stations the cables are now carried in ducts, but in many others, even among those recently constructed, the old plan of open wiring has been followed. This open wiring is without doubt cheaper and permits of making alterations to the wires more easily. Another advantage claimed by some for supporting the cables on racks is that space is saved, although such a saving, if it amounts to crowding, may be a disadvantage.

While the saving of space in stations such as those noted in the article on page 1452 of the Dec. 30 issue of the ELECTRICAL WORLD is always desirable, when it can be done without resulting disadvantages, and is sometimes necessary, yet open wiring is not a good way to save space as its very compactness militates against its use. In case of trouble on one of the cables, particularly one of the lower cables, there is great danger of the arc, or flame

from burning insulation, spreading to adjacent cables and the trouble increasing until many, if not all, of them are involved.

If the cables are run in conduit as far as possible inside of the station, there is little likelihood of the trouble spreading from one cable to another, because, even if they are nearly as close together as they would be if run on racks, they will be separated by the fireproof and arc-proof walls of the ducts.

By running the wires in conduits inside of stations a fire hazard both to the cables themselves and to the building is done away with.

## Instructions for Starting Turbo-Generators

BEFORE starting turbo-generators it is important to see that the slip rings are clean, that the brushes are properly adjusted to them and that the brush rigging is tight, in order that there may be no resistance to the flow of current on account of faulty conditions at these parts. The field resistance is all cut in at starting to prevent the possibility of dangerous voltage as the speed of the machine approaches normal value.

The primary object of an air washer when used with a generator is to cleanse the cooling air for the generator, thus preventing the clogging of the air ducts and the deposition of dust on the windings. Besides reducing the heat-transferring ability of the windings, dust deposits and oil form adhesive coatings which it is difficult or impossible to remove. Where they are not entirely removed the oil attacks the insulation and shortens its life. From clean windings or iron, on the other hand, oil can easily be wiped. A secondary effect of the air washer is the raising of the humidity of the air nearly to saturation, since moist air has a higher specific heat than dry air and consequently will take away more heat from the generator windings with the same rise in temperature.

Following are the instructions for starting turbo-generators which have been specified by the operating code of the Philadelphia Electric Company:

TURBO-GENERATOR STARTING

1. Signal the engineer "slow."
2. After receiving a return signal from the engineer and allowing sufficient time for the turbine to warm up, signal "speed." The time to warm up depends upon how long the machine has been out of operation and upon its size. If the machine is cold, the time allowance should be at least one minute for each 1,000 kw. capacity.
3. When a bracketed exciter is used for excitation, close the exciter circuit breaker.
4. Energize the field, having the field resistance all cut in.
5. Start the air-washer pump and make sure that spray is being produced properly.
6. On receiving the signal "Load" from the engineer, answer it and proceed to synchronize and parallel the generator with the bus to which it is to be connected. Synchronizing methods will be given in later issues.
7. Load the generator at approximately 1,000 kw. per minute.

## Putting Boiler on the Line from Banked Condition

FREELY blowing the superheater before the boiler is put on the line prevents any accumulated water from passing into the steam mains. The plates of the clinker crusher pit are protected from injurious heat by covering them with ashes winged back from the grate. Where dump plates are installed they are dropped to start the run with a clean fire.

The definite procedure for putting a boiler on the line from a banked condition as outlined in the operating code of the Philadelphia Electric Company is given below:

PLACING BOILER IN SERVICE

1. Blow down the water-column gage glass; test the gages by opening the gage cocks and see that there is not over 1½ in. of water in the gage glass when putting a boiler on the line.
2. Open the superheated drains wide and allow them to remain open until damper and stoker adjustments have been made.
3. Wing the ashes back on the clinker crusher, or drop the dump plates.
4. Close the dump plates.
5. Put the long stroke on the lower ram, in cases where hand-dump plates are used.
6. Shut off the draft on the extension grate.
7. Proceed according to rules 2 to 13, inclusive, published in the Feb. 3 issue of the ELECTRICAL WORLD, page 282, under the title "Detailed Instructions for Boiler-Room Force."

# Points to Consider in Locating Meters

IN CHOOSING a meter location it is essential that the instrument be placed where its maximum accurate registering life can be obtained. Locations subject to vibration, dampness, dust and mechanical injury are to be avoided as far as possible. While the life and accuracy of the meter should receive first thought, its proper location as to convenience in reading, inspecting and testing must not be neglected.

Formerly many meters were wrongly installed, irrespective of the inconvenience caused the electric company, in order to comply with the desire of the customer to get the meter out of the way or to permit the contractor to save a little money on the wiring job. This leniency has resulted in meters being placed on porches exposed to weather, on stairways, in bathrooms, bedrooms, closets, coal piles, attics, over windows and doors and in many other inconvenient places varying in height from the floor level to 15 ft. above the floor.

Poor location of meters not only reduces the number read in a day, but at the same time causes undue annoyance to the customer and is the cause of most errors in reading, or even of guesswork on the part of the meter reader, who dislikes to take the time and trouble to see the dial clearly. Mistakes in meter reading are embarrassing to the company; often time and expense are necessary in rectifying them, and possibly the good will of the customer is lost. Wrongly placed meters also increase the cost of testing.

The aim of every company should be to see that its meters are installed in the proper location. The cellar is usually the logical place. Merely to place the meter in the cellar is not enough, however. It should be easily accessible, not less than 4½ ft. nor more than 6 ft. above the floor, and as near the service entrance as possible at a point where no obstruction is likely to be erected. If the cellar cannot be used, the next best place should be chosen. Where the building is under construction a fireproof cabinet for the meters can often be placed in the wall at an accessible place.

The best method is for the electric company to require the contractor to make application for a meter location on a form furnished by the company before any wiring has been

done. The company then sends an inspector to determine the location, records the exact spot designated for the meter on the form sent in by the contractor, and either notifies the contractor orally of the desired location or sends him a duplicate of the form he filled out. It is often convenient for the service location to be designated at the same time. The form filled in by the company's inspector is turned over to the service and meter departments to serve as a check when the meter is finally installed.

## Test of Relay and Circuit Breaker Mechanism

TESTING of relays may indicate whether they will operate satisfactorily in service, but it gives no assurance that the control circuit is intact or that the circuit-breaker mechanism will function as desired. Still, all of these parts must perform their duties jointly or the best relay will be useless. Hence a power company in the Southern States makes a practice of testing the combined relay, current transformers, control circuit and breaker-operating mechanism regularly with a portable transformer connected between the two disconnecting switches on each side of each circuit breaker, so as to include these components.

The testing transformer has a 110-volt primary and a low-voltage secondary with several taps, thus permitting full, double or triple-rated current to pass through any circuit breaker. The transformer was made from an old 2-kw. machine, only the original iron core being used. The windings were adjusted until the desired current values were obtained.

In making the tests a cycle counter is used to determine the time required between application of the test current and the completed opening of the circuit.

## Meter Test Record

WHEN meters are tested on the customer's premises the conditions found and the adjustments made are too often left unrecorded, notwithstanding that the information may be of considerable value at a later date in meeting a customer's complaint, determining the necessary frequency of test or for another reason. With the inspection and test sheet reproduced herewith one large Southern company has been enabled to discuss intelligently any meter readings with its customers, and has besides been able to check its meter-test men and keep a record which is very helpful in establishing the required frequency of tests as well as the need or otherwise of changing meters. Though the information required may seem unduly elaborate, it

## Relay Nomenclature of the Electric Power Club

RELAY nomenclature as in the following list has been recently adopted as recommended practice by the Electric Power Club. The complete list is to be inserted in the next edition of the club's handbook of electrical apparatus standards under the heading of "Nomenclature." The definitions of the various types of relays and qualifying terms should assist materially in furthering clarity in specifications:

### CLASSIFICATIONS OF RELAYS BY FUNCTIONS

*General.* — Where relays operate in response to changes in more than one condition, all functions should be mentioned.

*Electric Protective Relay.*—An electric protective relay is an intermediate device, equipped with contacts to open or close an auxiliary circuit, by means of which one circuit is indirectly controlled by a change in conditions in the same or other circuits.

*Overload Relay.*—An over-current relay in the circuit of a motor is one which functions at a predetermined value of the current to cause the disconnection of the motor from the line.

*Directional Relay.*—A directional relay is one which functions in conformance with direction of power, or voltage, or current, or phase rotation, etc.

*Power-Directional Relay.*—A power-directional relay is one which functions in conformance with direction of power.

Note.—This includes both unidirectional relays with single-throw contacts and duodirectional relays with double-throw contacts. The reason this name is preferred to "reverse power" is that the device is frequently used to function under normal direction of power. Furthermore, in some cases the normal condition of the system may permit power to flow in either direction. Relays for use in either alternating-current or direct-current circuits are to be classed as power-directional relays.

*Polarity-Directional Relay.* — A polarity-directional relay is one which functions by reason of a change in direction of polarity.

*Phase-Rotation Relay.* — A phase-rotation relay is one which functions by reason of a change in direction of phase rotation.

*Current-Relay.*—A current relay is one which functions at a predetermined value of the current. These may be either over-current relays or under-current relays.

*Voltage Relay.* — A voltage relay is one which functions at a predetermined value of voltage. These may be either over-voltage relays or under-voltage relays.

*Power Relay.*—A power relay is one which functions at a predetermined value of watts. These may be either over-power relays or under-power relays.

*Frequency Relay.* — A frequency relay is one which functions at a predetermined value of frequency. These may be either over-frequency relays or under-frequency relays.

*Temperature Relay.*—A temperature relay is one which functions at a predetermined temperature in the apparatus protected.

*Open-Phase Relay.* — An open-phase relay is one which functions by reason of the opening of one phase of a polyphase circuit.

*Differential Relay.*—A differential relay is one which functions by reason of the difference between two quantities such as current, or voltage, etc.

Note. — This term includes relays heretofore known as "ratio balance relays," "biased relays" and "percentage differential relays."

*Locking Relay.* — A locking relay is one which renders some other relay or other device inoperative under predetermined values of current, or voltage, etc.

*Trip-Free Relay.*—A trip-free relay is one which prevents holding in an electrically operated device such as a circuit breaker while an abnormal condition exists on the circuit.

*Auxiliary Relay.*—An auxiliary relay is one which assists another relay in the performance of its function and which operates in response to the opening or closing of the operating circuit.

*Signal Relay.*—A signal relay is an auxiliary relay which operates an audible or visible signal.

### GENERAL QUALIFYING TERMS

*Inverse Time.* — Inverse time is a qualifying term applied to any relay indicating that there is purposely introduced a delayed action, which delay decreases as the operating force increases.

*Definite Time.* — Definite time is a qualifying term applied to any relay indicating that there is purposely introduced a delayed action, which delay remains substantially constant regardless of the magnitude of the operating force. (For forces slightly above the minimum operating value the delay may be inverse.)

*Instantaneous.* — Instantaneous is a qualifying term applied to any relay indicating that no delayed action is purposely introduced.

*Notching.*—Notching is a qualifying term applied to any relay indicating that a number of separate impulses are required to complete operation.

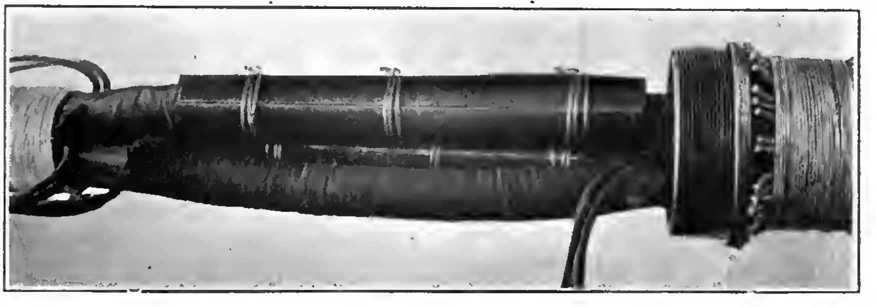
# Eight-Mile Cable Under San Francisco Bay

**Operated Successfully at 11,000 Volts by the Great Western Power Company—Method of Handling, Splicing, Testing and Laying Outlined**



JOINT SLEEVE SCREWED TO THREADED COLLAR CLAMPED BENEATH CABLE ARMOR WIRE

WHAT is believed to be the largest and longest submarine power cable in the United States for operation at 11,000 volts has recently been laid by the Great Western Power Company. The cable, approximately 8 miles in length, runs beneath San Francisco Bay from Pier 41, San Francisco, and connects with the mainland near Richmond, Calif. Many unusual features are embodied, both in construction and in the method of laying that was followed.

The main cable is of the three-conductor type, each conductor composed of thirty-seven tinned copper wires and each wire having a diameter of 0.1162 in., with a total area of 500,000 circ.mils and an outside diameter of the copper strand of 0.813 in. Each of these conductors was insulated with special high-grade rubber compound of $\frac{12}{32}$-in. radial thickness. Over this rubber insulation was wound, spirally, a rubber-filled tape. The conductors, after vulcanizing, were laid up into a cable, the three interstices of which were filled with saturated jute and three pairs of telephone conductors. The telephone conductors are composed of No. 14 A.W.G. stranded tinned-copper wires, insulated with special high-grade rubber compound to a $\frac{3}{32}$-in. radial thickness. After insulating, each

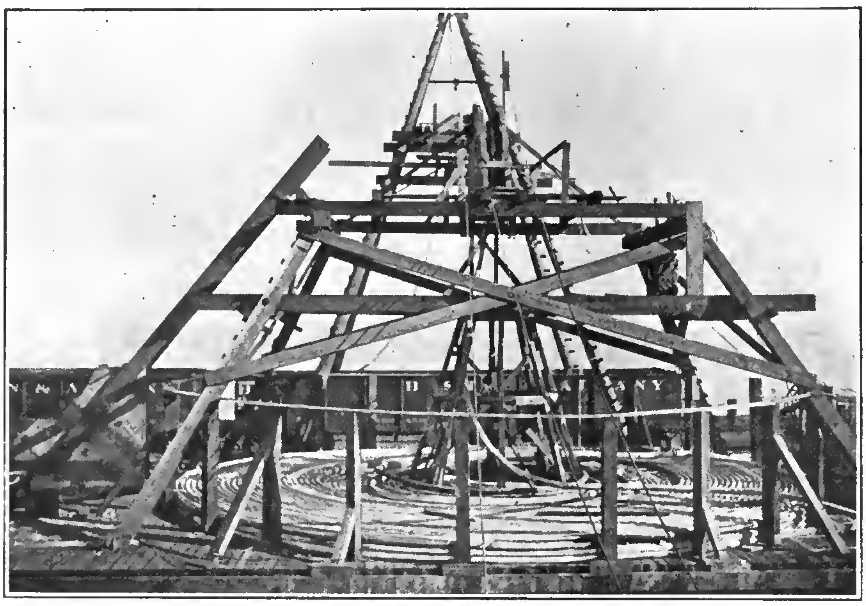
telephone conductor was spirally wrapped with rubber-filled tape and vulcanized, then stranded into three separate pairs, the interstices of which were also filled with saturated jute. After laying up the three main conductors, three pairs of telephone conductors and saturated-jute fillers, the cable received a serving of rubber-filled tape. Over this tape two servings of saturated jute were applied, laid on in opposite directions. It was then armored with forty-three galvanized-steel wires, each wire having a diameter of 0.244 in., making the outside diameter of the cable approximately 4½ in. The weight when completed was approximately 20 lb. per foot.

The shore ends were of similar construction, except that the conductors were composed of sixty-one tinned-copper wires, each 0.1109 in. in diameter, with an outside diameter of the strand of 0.998 in. and a total area of 750,000 circ.mils. The outside diameter over the armor, which in this case required forty-eight galvanized-steel wires, was 4.6 in. Over the armor was wound a saturated-marline serving, making a total outside diameter for the shore ends of approximately 5 in., with a total weight of approximately 24 lb. per foot. The length of the shore ends on the San Francisco end was 250 ft.; that on the Richmond end was 750 ft.

These cables were manufactured in Worcester, Mass., the deep-sea section being made up in lengths of approximately 5,000 ft. and coiled and shipped in gondola cars, this 5,000-ft. unit being the capacity of one gondola car.

The cable was tested in process at the various manufacturing stages at the mill, and then each carload received a final test for a period of five minutes while submerged in water at a test potential of 35,000 volts between each conductor and ground. While en route from Worcester, Mass., to San Francisco the different cars of cable averaged thirty days for the transcontinental journey and arrived in perfect condition.

Upon arrival in San Francisco the cable was joined into a continuous length and coiled on board a specially constructed barge designed to carry 1,000 tons. The method of coiling, jointing and laying the cable was developed by A. O. Hoeftmann and perfected during his period of service with the American Steel & Wire Company and in laying deep-sea transatlantic cables. A feature was the type of deep-sea cable joint employed. This, by its construction, permitted of easy passage over the guide sheaves, besides having practically the same tensile strength as the main cable and possessing great dielectric strength.



CABLE COILED ON DECK OF VESSEL WITH FACILITIES TO PREVENT FOULING WHEN UNCOILED RAPIDLY

In the making up of this joint the copper-stranded conductors were connected by means of a special copper sleeve, the rubber insulation being tapered off on each end of this sleeve and a special rubber tape wound on —in other words, it was filled in with rubber slightly thicker than the original insulation—after which half-round steel molds were clamped over this new insulation and then the joint was put into a bath of compound heated to the proper temperature and was vulcanized.

The cable was taken from the cars, jointed and coiled upon the deck of the cable-laying vessel in a circular coil 42 ft. in diameter and with an inner diameter of 12 ft., the coil being approximately 6 ft. high. After the construction work for laying equipment was completed and the cable jointed and coiled on board in a continuous length, a final test was made before laying.

The cable, while in process of laying, passed from the coil around a cone in the center and in an upward direction to a series of shrouded sheaves; then through a trough and through a number of lever-operated brakes to a shrouded stern-piece, over which it passed into the water. The varying depth of the water determined the amount of brake friction necessary to control the speed of the cable while the barge was being towed by three large seagoing tugs. After laying approximately 6 miles of cable through deep water and strong tidal conditions at the start from San Francisco to beyond Alcatraz Island, the shallow water necessitated changing from the large tugs to three of lesser draft.

The entire operation of laying was carried out most satisfactorily, the cable being under control at all times, and no difficulty was encountered in maintaining the course as originally planned. The total time for laying the cable was two hours and thirty-seven minutes, making an average speed of about 3 miles per hour.

The services of A. O. Hoeftmann and J. J. Morrison, cable engineers, and John Marlborough, expert cable jointer, were obtained from the American Steel & Wire Company to superintend the installation of this cable.

J. A. KOONTZ,
Electrical Engineer.
Great Western Power Company,
San Francisco, Calif.

## Grounding of Switchboard Instruments

WHERE meters and instruments are used with current and potential transformers, the Electric Power Club recommends that when the covers of the meters and instruments are connected to the secondary circuits and grounded the ground conductor need not be larger than a No. 12 B. & S. copper wire.

## Marketing Central-Station Service

### Sales Possibilities Have Been Overlooked in an Effort to Lower Manufacturing Costs—How the New-Business Department Should Be Organized

By Glen R. Trumbull

Head of New-Business Department, A. E. Fitkin & Company, New York

IT HAS taken a long time for the central-station company to realize that fundamentally its problems are the same as those of any other manufacturer—after the product has been made it must be sold. For years we have been so beset with tremendous engineering problems that the marketing of kilowatt-hours has been slighted. We were so eternally busy trying to manufacture energy at the lowest possible cost that we forgot the equally vital need of selling it at a profit.

We have been, and some of us are still, too content and satisfied with the natural increase in business; we expect the public to come to us with their demands and needs. It is fortunate indeed for some of us that there has been such a natural increase; that the public is alive and desirous of buying that which we have to sell, otherwise some companies' output and earnings would remain at a standstill.

New-business operations to function successfully require a regularly organized department with a specialist at the head, one who is trained to concentrate on the develonment of all the possibilities for increased gross earnings in the big field which exists in all of our communities today. Every property, no matter how small, needs the services of at least one man. Such a man, picked with an eye to two cardinal requisites of a good new-business man—common sense and industry—will approach his problem in the following general manner. He will first make a complete survey of the community served —every house, store, factory and plant—to find out these essential facts:

Who owns the property?
What is being used for illumination?
What is being used for fuel?
Is the place wired?
Is there gas service?
Is the service alive or dead?
What appliances are installed?
Are they in good working order and being used?
For what is the property an immediate "prospect?"

There are many more questions which, if time permits their compilation, will give a still more complete picture of the new-business possibilities—who and what the prospects are.

In the residence district this survey will show the number of dead services—a class of business on which to make the first drive and which it is the ambition of every live manager to see reduced to zero. Dead services not only produce no revenue but actually cost money because of the investment in equipment lying idle. This survey will also show the number of houses on lines not using service, which is the next best bet in desirable business. From this survey can be anticipated the most profitable extensions, those requiring the least expenditure for the greatest number of new customers. Finally the exact number of "prospects" for appliances can be determined and the particular one for which each customer is a prospect.

In the commercial or business district this survey will bring out the present low standard of illumination, the lack of realization of the average merchant and store keeper of what an important factor good and efficient illumination is in the appearance of the store and its direct relation to the net results of the cash register.

#### Importance of Lighting

Lighting yields approximately 59 per cent of the total operating revenue of the average central-station company, although it comprises only about 23 per cent of the total load. When one considers this fact it becomes apparent why the importance and value of the central station's lighting business cannot be too strongly emphasized.

Merchants everywhere today are in a most favorable frame of mind toward good illumination. Few will deny the importance of illumination in drawing and holding trade, and competition is keen—a big factor in making the merchant eager to invest in anything within reason that will make his store conspicuous and bring in new buyers. And so it is with window lighting and signs.

The average merchant thinks of lighting in terms of profit to his store. He is most easily "sold" on the idea that better illumination, which to his mind always means brighter illumination, will bring more trade. Merchants who have installed better illumination and electrical advertising cite many specific results, such as greater profit, fewer returned goods, improved courtesy and more regular attendance on the part of salesmen, the better sale of slow-moving gooods, the speeding up sales, greater cleanliness and better reputation of the store.

#### Electrical Advertising Must Be Sold

Electrical advertising is not confined to Broadway. In every city in this country there are progressive merchants as keenly alive to the value of electrical advertising as those in the larger centers, but they have got to be approached, they have got to be told the story, they have got to be "sold" by the central-station man.

But here is one fact: The poorest advertisement for electrical advertising is an old dirty sign hanging over the central-station office. How can we expect to interest others in the kind of advertising which we have to sell if we don't present a shining example at our own place of business? A central-station sign ugly from need of paint, with a lot of burned-out lamps, is as bad as no sign at all, worse if anything—it's a constant reminder to any prospective purchaser of what his sign may look

like a little while after its installation. As for window lighting, ours should always be the last word in luminaires and in intensity — the brightest in town—a working demonstration to influence storekeepers to more and better lighting.

### The Central Station's Position on Appliance Sales

Merchandising is recognized as and proved conclusively to be one of the most important and necessary functions of a live and up-to-date central station. Failure to press to the fullest extent the natural advantage any electric light and power company possesses in this line over any form of so-called competition is as bad as failure to install a new boiler at the plant which will reduce the coal consumption 2 lb. per kilowatt-hour.

Customers look to the company for advice and help in their purchases of those appliances and apparatus using our service. They expect us to sell the highest grade manufactured and to display a good variety of the standard articles which they have come to recognize as necessary for their comfort and many of which have become indispensable.

But to merchandise successfully a central station must put its salesroom and display windows in the same class with those of the successful merchants of the community. They must be brilliantly lighted with attractive and suitable fixtures. Appliances must be tastefully displayed, windows should be artistically and frequently trimmed, courteous and prompt attention must be accorded to prospective purchasers, and, most important, everything must be kept clean. It is sad but true that the average central station which thinks it is merchandising invariably neglects a few and sometimes many of these essentials.

With the public in a purchasing frame of mind, eager to buy electrical devices, and the manufacturers co-operating on a scale unknown and unheard of in other lines of industry, the majority of the central stations of this country are indifferent to or laggard in grasping their opportunity. The manufacturers are today spending hundreds of thousands of dollars annually in national advertising, sales plans, advertising literature and the services of demonstrators and expert salesmen, but how many of us take advantage of this help?

Success in merchandising is dependent on logically and intelligently planned sales programs and the employment of real salesmen. These salesmen are the representatives of the company. No official or employee in the entire organization is of more importance than he who sells and places appliances in the homes. His importance does not consist in the mere ability to fill a house with appliances. It is his ability to show that home how to get the largest possible benefits and advantages through the use of electricity. This man should be more than a mere solicitor. He is one of those who form the contact between the company and the community and therefore a big link in the chain that binds the company to its customers. And that chain is no stronger than his standing in the confidence and good will of these customers.

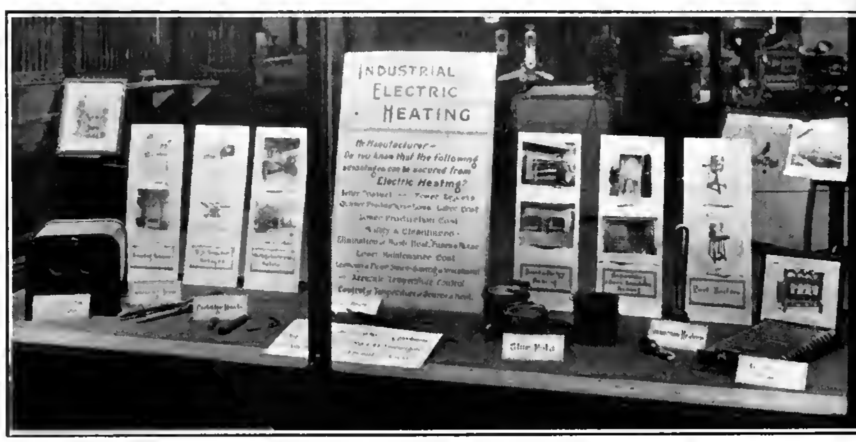
One thing more—there isn't such a thing as saturation, or even "near saturation," in public utility operations, least of all in new-business work. The history of one of the most successfully operated plants in this country—the one with the first regularly organized new-business department—in over twenty-five years shows a healthy increase in earnings year after year. The new-business department has never ceased its activities; it has grown larger and larger, and each year it continues to beat its record of the year previous. So it can be with every central-station company.

## Range Load Growing Fast in Chattanooga

During 1922 the Tennessee Electric Power Company connected 333 electric ranges in Chattanooga by offering a combined lighting and cooking rate and selling ranges on the installment plan. For the first 40 kw.-hr. it charges 9 cents a kilowatt-hour and for all consumption above that it charges 3 cents. The average domestic bill for homes using electric ranges is $6.91 per month. The ranges have been connected despite the competition of coal at $8 to $12 per ton and gas at $1.50 per 1,000 cu.ft. In selling the ranges the customers are required to pay 10 per cent of the price down and 10 per cent per month. E. D. Reed is general superintendent of the Chattanooga district.

## Promotion of Industrial Electric Heating Load

The accompanying window display of industrial heating apparatus was used recently by the New York & Queens Electric Light & Power Company of Greater New



WINDOW DISPLAY SHOWS INDUSTRIAL HEATING APPLICATIONS

York as a part of its program to inform manufacturers of the advantages of electric heating. Especial attention is being given by the company to the many applications of small units which in the aggregate mean a very considerable electrical load for the central-station company.

E. H. Hillock, industrial sales engineer of the company, plans to follow this display with additional exhibits at which other electrical apparatus about which industrial plants should be informed will be featured.

The commercial department of the New York & Queens Electric Light & Power Company foresees great possibilities for developing an industrial electric heating load in its territory, the latest addition being the installation of three electric brass furnaces, totaling 550 kw.

## Tenney Management Gives Inside Utility Facts

A NEW series of public-relations advertisements was started early this year by the Haverhill (Mass.) Electric Company and the Montpelier (Vt.) & Barre Light & Power Company, under the general management of Charles H. Tenney & Company, Boston. The object is to expand the messages conveyed in last year's historical press displays to dimensions giving the local publics a straightforward, clear conception of the differences between the management of a private business and the conduct of a public utility, showing the limitations existing as to profits in the ordinary sense of the word in the utility field and pointing out the bearing which state regulation has upon company administration and development.

Referring to the accompanying reproductions of six Haverhill advertisements as so far scheduled, No. 1 has for its keynote a "tie-in" between the 1922 advertisements and the new series; No. 2 sets forth the real meaning of regulation as relating to prices of industrial products and of electric service, and No. 3 contrasts the profits permitted in ordinary business with those limited to the form of a return on capital invested in a public utility. The right of money to a fair return in the utility field is set forth in No. 4, and in No. 5 the real meaning of regulation is brought home to the business man by assuming its application to his own affairs. In the sixth display the part profits play in building up a great automobile manufacturing business is contrasted with the limitation placed upon public utilities, which must obtain their expansion through the investment of new capital. The series will be continued for a number of months according to present plans.

### A new series of short talks

**On a matter of vital importance to every citizen**

FOR SOME TIME we have been telling you the story of the Public Utility—its origin, its purpose, its development in response to public need.

We now propose to tell you, in a series of short talks, how the Public Utility functions.

A Public Utility—just because it is a *public utility*—operates under conditions radically different from those that obtain in the ordinary private enterprise. Few people realize this fact. Yet it is a matter of vital importance to every member of the community.

It is our purpose, therefore, to tell you why a Public Utility differs from a private business, how it differs, and in what way this difference affects its relations with the public which it serves.

It is our hope that by presenting these facts we may help you to become better acquainted with this Company and with the problems that confront it in carrying out the task to which it is committed—furnishing a necessary service to this community.

HAVERHILL ELECTRIC COMPANY

### You may have heard this one

*But it's worth repeating. It illustrates an important point*

ONCE upon a time—not so many years ago—the directors of a newly organized company held a very important meeting.

They were deciding whether to charge $1 or $5 for a patented article which the company was about to put on the market.

All the evidence indicated that they could profitably market the article for $1.

Nevertheless, they set the price at $5 and maintained it at $5 until their patents ran out

This article undoubtedly saves its cost two or three times a year—and it lasts ten or twenty years. Therefore, men have asserted that the price was fair, that the inventor and the investors who made this article available to the public were entitled to a goodly return.

We do not venture to discuss the justification of that price. What we should like to point out is this:

*If that company had been a public utility, it could not have charged $5. The law would have prevented it.*

Massachusetts' Public Utilities are regulated by the state. The rates they charge are subject to the jurisdiction of the Public Service Commission.

HAVERHILL ELECTRIC COMPANY

### John Jones may make business profits

*A public service corporation may not*

JOHN JONES receives a good salary.

He has $10,000 invested in gilt edge securities.

When John Jones goes into business for himself he expects certain returns from that business. He expects to get his salary—for he is his own employee. He expects to get the same interest on the money invested in his business as he got when it was invested in other businesses.

But he expects something more. Naturally. If he gets only the same salary and the same return on his investment, he gains nothing by going into business.

This something in excess of operating expenses and interest on investment is called business profits.

When you buy shoes or tooth paste or theatre tickets or automobile tires, you pay operating expenses and investment charges *plus profits*.

But when you buy electric light or power, no part of your money goes for profits.

The Haverhill Electric Company, like all public utilities, is regulated by the state. Its rates are subject to the jurisdiction of the Public Service Commission.

The rate you pay for light and power is simply your proportionate share of the cost of supplying such service.

HAVERHILL ELECTRIC COMPANY

FIRST SIX OF A SERIES OF PUBLIC RELATIONS ADVERTISEMENTS

### Money, like men, works for profits or for wages

*In the public utility industry it must work for wages*

SOME men in business work for profits. These men may amass great fortunes. They take risks; but they are compensated for those risks by the opportunities for enormous returns.

Other men work for wages. Their remuneration is fixed. They can never amass great fortunes. On the other hand, so long as their services are required, so long as they render such services faithfully and efficiently, they are entitled to a sure and a fair return for their efforts.

Money is like men. Some money is risked for great profits. Money invested in private enterprises may earn 10 per cent or 100 per cent or 1,000 per cent.

But money invested in public utilities is on a wage basis. Its remuneration is limited by law. It is prohibited from earning business profits like money invested in private enterprises.

The money invested in the Haverhill Electric Company is necessary to provide light and power to the people of this community.

Since the service of this money is required, since that service is rendered faithfully and efficiently, since this money is prohibited from seeking profits like that in a private enterprise, since this money is therefore on a wage basis, is it not entitled—like any other wage earner—to a sure and a fair return?

HAVERHILL ELECTRIC COMPANY

### "Public Regulation"

*As applied to your business*

YOU frequently hear the expression "public regulation." But does that phrase really have any vivid meaning for you?

Let's see what it would mean if applied to your business.

Suppose some public authority told your company what product it might make, what quality of product it might offer for sale, what price it might charge, how much capital it might have invested in its business—then your company would be under public regulation.

Massachusetts' public utilities are regulated by the state. The character of the service furnished, the rates charged for that service, the securities issued to provide the necessary capital—all are subject to the jurisdiction of the Department of Public Utilities.

The very existence of a modern community depends upon service rendered by public utilities. Under public regulation, wisely and justly administered, the interests of the public utility and the public served are adequately safeguarded.

Because of such regulation, a public utility necessarily operates under very distinct limitations—limitations that are in marked contrast to the freedom which a private enterprise enjoys.

HAVERHILL ELECTRIC COMPANY

### What is an industrial genius?

*And who contributes to his greatness?*

A MAN starts a small business—making automobiles, let's say.

He sets a price on his product so that it pays all operating expenses, pays insurance and interest, pays dividends, allows for depreciation and contingencies, and leaves an excess of profits.

These profits, put into his business, permit him to operate on a slightly larger scale.

He continues this process of earning profits, putting them into his business, and operating on a larger and larger scale until he has built up a great industry.

That is a proper and admirable procedure. But let us not forget that the people who bought that man's products supplied the money necessary for the expansion of his business.

Let us bear in mind that a public utility is forbidden by law to follow that man's example.

Unlike the automobile business, the public utility cannot set a price on its service which will enable it to pay all costs of operation and in addition provide the money necessary for extending its plant.

HAVERHILL ELECTRIC COMPANY

# Appliance Load in Small Cities

## With Few Industrial Opportunities in Agricultural Sections, Residential Business Should Be Fully Developed—Increasing Lamp Wattage to Improve Lighting

By Arthur Huntington
Iowa Railway & Light Company, Cedar Rapids, Iowa

During the past few years central-station companies, particularly in the smaller cities and towns, have placed many appliances with consumers. The independent dealers also have made heavy sales of them. A study of the replacement sales leads to the belief that there must be many of these appliances that are not in use. In the case of the electric flatiron one property having a record of the sale of about forty thousand irons shows a replacement sales record that indicates a life for the irons in use of approximately twenty-five years. More than thirty thousand sales were made prior to 1918. This record extends over so long a period that the replacement sales should be on a normal basis, provided proper use of the irons is being made.

The indications are that the same condition exists where other appliances are concerned. The largest single factor in the situation is probably the fact that appliances get out of repair and are set on the shelf until a convenient time of repair that never comes. A trial of the plan of sending out a man whose only business is to ferret out and repair such appliances indicates that not only can such appliances be returned to service, but the man can make a good wage day in and day out.

### Increasing Lamp Wattage

Another plan for developing business in the same communities is to promote better lighting both in homes and stores. In the case of a small Iowa town a check on lamp sales revealed that the average size of incandescent lamps sold was in the neighborhood of 27 watts, while 10-watt and 15-watt lamps formed the largest part of the stock on the dealers' shelves. In many cases a large part of the population of these small communities comes from the farms, and in others electric lighting is a comparatively new thing. The customers when they discard oil lamps use incandescent lamps that give a great deal more light than the previous utensils, and until they are educated to it they have no appreciation of the value or comfort of really good lighting. That educational work is the job of the central station as a part of its commercial activities.

Another appliance that promises much in the small towns is the electric range. Experience in the smaller towns of Iowa indicates that the customs are such that even when the days of the year are shortest there is no serious overlapping of the lighting and cooking loads. It has also been shown that in these small towns a heavy range load can be handled with no increase in the cost of the distribution system over that of the haphazard system ordinarily used in supplying lighting customers. Application of engineering principles has accomplished this in cases where a deliberate development of the range business has been undertaken in small towns.

### Education of Customers

Central station companies' experience in the use of the range has extended over a long enough period to show that there is no serious obstacle to it from the cost standpoint. The biggest factor in this phase of the problem is the education of the customer to an intelligent use of the range. In the case of two small towns, one paying a 5.4 cent rate and one a 4.5 cent rate per kilowatt-hour, the revenue per range is practically the same and there is no dissatisfaction. Rates have cut less figure than proper education.

These three items may not appear to be big ones in the commercial policy of a central station. In sections where industrial developments are large they will be of less importance. But in the smaller cities in agricultural sections they form avenues along which the biggest development of the business must take place. Many small companies have spent time and effort in securing all the possible customers in their territory and have forgotten that use of service is the only means of building up the business. These three items form the biggest possibility of consumer development in much of the agricultural territory of the Middle West because there are no industrial developments from which to build up a power load. Experience indicates that in many small towns the consumers already connected can be profitably developed beyond the ordinary limits of consumption so that the company will receive more than would be received from the average ordinary new customer, for whom an additional investment would have to be made.

## What Other Companies Are Doing

**Indianapolis, Ind.** — A campaign to sell 2,500 shares of prior-lien stock of the Interstate Public Service Company was started by the company's investment department on Jan. 18. Prizes will be distributed to employees for the largest single sale, largest number of sales and for the greatest number of shares sold.

**Hartford, Conn.** — The Hartford Electric Light Company has arranged to alter the third and fourth floors of its office building to provide a dining room for the women employees and officers of the company. A pool room and rest rooms will also be provided.

**Franklin, Mass.** — During December the Union Light & Power Company's business in a territory with four thousand customers was in excess of $10,000, or over twice the business of December, 1921. During the past year this company has paid special attention to the development of industrial heating applications and heavy-duty types of electric range service for lunchrooms, new roadhouses, etc., and this work will be pushed this year with electric refrigeration.

**Greeley, Col.** — Colorado's third electrical home was opened here from Jan. 5 to 12 with an attendance of 5,027 during the eight days. The total cost to the electrical interests was less than $400. The individual cost per person inspecting the home was less than 7 cents and the total attendance represented 45 per cent of the population.

**Seattle, Wash.** — According to data presented at a recent convention of Stone & Webster, Inc., managers at Boston, employees of the Seattle division of the Puget Sound Power & Light Company oversubscribed a preferred stock allotment of $200,000 by 12 per cent in a campaign last year. The total number of employee subscribers was 1,240, despite the fact that the company had previously sold $668,000 of five-year 8 per cent notes to 2,000 employees.

## Hydro-Electric Development and Steam Equipment

*Power-Plant Extension.*—The Walsall Corporation (England) has increased its 14,000-kw. station at Birchills by adding a 5,000-kw. Brush-Ljungstrom turbo-alternator set. Several interesting tests on this set have been completed. The accompanying table shows the results obtained from the set over a test lasting six hours. For this test the load varied from 3,700 kw. to 5,415 kw., and the coal consumption was 1.92 lb. per kw.-hr. generated, its calorific value being 10,160 B.t.u. per lb. and the thermal efficiency 17.49 per cent.—*Electrical Review*, Dec. 29, 1922.

TEST ON 5,000-KW. BRUSH-LJUNGSTROM TURBO-ALTERNATOR SET

| | |
|---|---|
| Average load, kw. | 5,030 |
| Steam pressure, lb. per sq.in. | 166 |
| Steam temperature, deg. F. | 662 |
| Vacuum (barometer 29.95 in.), in. | 28.90 |
| Cooling water temperature: | |
| Condenser inlet, deg. F. | 49 |
| Condenser outlet, deg. F. | 61 |
| Average condensate per hour, lb. | 52,100 |
| Steam consumption, lb. per kw.-hr. | 10.36 |

*Steam Engineering Practice in Modern Central Stations.*—T. E. KEATING.—The upper limits of pressure and temperature for a central generating station are set by the materials commercially available and, with the exception of financial considerations, are determined wholly by conditions within the plant. For these reasons steam pressures and temperatures have not reached the stage of standardization prevailing in electrical units. This article discusses a few of the thermal and operating problems that are today under consideration by central-station engineers, explaining their influence on the economic generation of power in modern central stations. — *Electric Journal*, December, 1922.

## Generation, Control and Instruments

*On Booster Transformers.*—J. SAHULKA.—It is shown that if feeders are connected to a line and their voltage is to be increased or decreased with the aid of a booster transformer, it is sufficient to equip this transformer with a primary winding dimensioned for only the difference of the energy corresponding to the amount of "buck" or "boost."—*Elektrotechnik und Maschinenbau*, Dec. 24, 1922.

*A Magnetically Self-Locking Disconnecting Switch.*—VLADIMIR KARAPETOFF.—It has been found that the usual mechanically locked switch has been unsatisfactory in high-current work because of the high magnetic stresses set up. The author has developed several switches in which a magnetic field aids in holding the switch in place. This is accomplished by placing coils above and below the switch blades in such a manner that the flux tends to hold the switch in place.—*Sibley Journal of Engineering*, January, 1923.

## Transmission, Substations and Distribution

*Electrical Oscillations on Lines.*—LOUIS COHEN.—The subject of electrical oscillations on telephone, telegraph and power transmission lines is so large and complex that any new presentation which will help to make it more intelligible to engineers and perhaps facilitate the solution of the many problems involved should prove of value. It is claimed that the methods developed in this paper for the solution of this class of problems offer many advantages in the matter of directness and simplicity. A limited number of cases are worked out, but the method is applicable to the solution of many others.—*Journal of the Franklin Institute*, January, 1923.

*Heating of Polyphase Cables with Metallicized Sections.*—C. FELDMANN.—Polyphase cables have recently been used in America the individual conductors of which were covered with a layer of copper ribbon 0.1 mm. thick. It was found that such a cable had a smaller dielectric loss and carried more current than an equivalent cable without the copper ribbon. Similar cables with a layer of zinc or aluminum ribbons 0.03 mm. thick have been used in Europe. The author gives a simple approximate method for calculating the heat resistance of such a metallicized cable which permits of drawing conclusions as to its higher current-carrying capacity. The author illustrates his calculating method on six actually built metallicized cables, three with a copper and three with a zinc ribbon, and finds that the cables with the copper ribbon may carry 38 per cent more current and the ones with zinc ribbon 15 per cent more current than similar cables without these ribbons. The method for drawing isotherms for three-phase cables is given in an appendix.—*Elektrotechnische Zeitschrift*, Dec. 21, 1922.

## Units, Measurements and Instruments

*Power Losses in Insulating Materials.*—E. T. HOCH.—It is shown that a satisfactory measure of power loss in a dielectric is the product of phase angle and dielectric constant. Although the dielectric constant need not be explicitly considered in the design of condensers, it is important in such cases as the design of apparatus panels and vacuum-tube bases. The method used in measuring phase angle and dielectric constant is explained.—*Electrical Communications*, Vol. I, No. 2.

*Tables for the Calculation of the Inductance of Circular Coils of Rectangular Cross-Section.*—F. W. GROVER.—The tables presented in this paper are calculated from accurate formulas, more than one formula having been used wherever this was possible as a check on the results. The tabulated values are correct to one part in ten thousand, and even where a double interpolation has to be made, the error is less than one part in a thousand. If desired, curves can be constructed from the data of the tables, with, however, a sacrifice in accuracy. Examples are given to illustrate the use of the tables and formulas in practical cases, and the application of the tables to the calculation of the mutual inductance of coils of rectangular cross-section is treated and illustrated and the necessary formulas developed. The formulas on which the tables are based are collected for reference in an appendix.—*Scientfic Paper No. 455 of the Bureau of Standards.*

## Illumination

*Illuminating Engineering Society Paper.*—This issue of the *Transactions* includes six papers that were presented at the Swampscott convention last fall. An abstract of the following four may be found in the convention report in the Oct. 7 issue of the ELECTRICAL WORLD, pages 760 and 761: "Relative Performance of Tungsten-Filament Lamps," by J. W. Lieb; report of the committee on motor vehicle lighting, "Influence of Daylight Illumination Intensity on Electric Current Used for Lighting," by A. Smirnoff, and the report of committees on nomenclature and standards. The other two, "Direct Reading and Computing Attachment for Sphere Protometers," by B. S. Willis, and "Plotting of Spectrophotometric Data," by F. A. Benford, may be found abstracted in the Oct. 21 and Oct. 14 issues, pages 892 and 835, respectively.—*Transactions of the Illuminating Engineering Society*, January, 1923.

## Motors and Control

*Practice in Maintenance Work.*—E. H. HUBERT.—Among the questions answered in this survey of seventy-four industrial plants are what to include in the maintenance work, method of handling maintenance, frequency of inspection for different equipment, most frequent causes of motor failures, and the character and amount of parts and supplies to keep in stock for all maintenance work.—*Industrial Engineer*, January, 1923.

*Water-Pumping Station in Württemberg.*—O. GROSS.—A general description is given of a large water-pumping station for the supply of several cities. Its output is about 65,000 cu.m. of water per day, pumped to a high-

est level of 148 m. The station contains five sets of centrifugal two-stage pumps, each driven directly by a three-phase induction motor at 985 r. p. m. To give the greatest possible flexibility of service according to water requirements, each pumping set is of a different size, varying from 540 hp. to 1,500 hp. A section is shown of the largest pump. To be insured against a total breakdown in the case of a failure in the 50,000-volt, three-phase feeding line, a sixth pumping set is installed, driven by a Diesel motor.—*Zeitschrift des Vereines Deutscher Ingenieure*, Dec. 9, 1922.

*Electric Equipment of Oil Wells in Rumania.*—C. REY and M. WILFART.—The authors describe the drilling methods used in Rumania, the necessary tools and the average cost of a new well. Three-phase motors are used throughout. All switches and controlling apparatus are of the oil-submerged type such as is used in mine practice. As an example full details are given for a reversing controller to operate a wound-armature, three-phase, slip-ring motor. — *Revue Générale de l'Electricité*, Dec. 16, 1922.

## Heat Applications and Material Handling

*Welding as a Factor in Steel-Plant Maintenance.* — E. R. NORRIS. — The welding practice of the Pittsburgh Steel Company is described in this paper.—*Journal of the American Welding Society*, December, 1922.

*Better Methods of Handling Materials.*—F. E. GOODING.—Trends and developments in better methods of handling materials which may be adopted in industrial works to increase production and reduce costs are described. The author asserts that whenever reduction in costs and increases in production are being studied, or when it is desired to put production on a more even flow of work, with schedules and a dispatching system to route it through the plant, it is well to investigate all the available methods for handling materials. —*Industrial Engineer*, January, 1923.

## Electrophysics, Electrochemistry and Batteries

*Primary Cell with Air Depolarizer.*—M. FOURNIER.—During the war, when manganese bioxide became very scarce, a new primary cell for telegraph purposes was developed in France, known as the Fery cell. It consists of a glass vessel containing at the bottom a zinc plate above which hangs a large carbon block. A solution of ammonium chloride serves as electrolyte. During operation heavy chloride of zinc is formed around the zinc pole, while lighter $NH_4OH$ is formed along the carbon, rising to the surface of the liquid. The author claims that prolonged tests, extending over two years, showed a remarkable superiority of these Fery cells over the manganese batteries that had previously been generally used. To compare the Fery cell with two known manganese-type cells, one of each was closed over a 50-ohm resistance, and the voltages given in the accompanying table were observed.—*Revue Générale de l'Electricité*, Dec. 30, 1922.

| Type | Initial Voltage | Length of Test, Days | Voltage at End of Test | Voltage Drop per Ct. per Day |
|---|---|---|---|---|
| Carbon in porous container with zinc rod | 1.48 | 45 | 0.74 | 1.16 |
| Carbon in bag, concentric zinc cylinder | 1.52 | 45 | 0.76 | 1.11 |
| Fery cell... .... .. | 1.25 | 100 | 0.625 | 0.50 |

*Effect of Temperature on the Mechanical and Microscopic Properties of Steel.*—G. C. PRIESTER and O. E. HARDER.—An investigation to study the mechanical properties of steels at elevated temperatures, the properties of the same steels at ordinary temperature after they have been heated to various drawing temperatures and the correlation of these properties with the microstructure of the steels has been carried out by the authors. It was found that the properties of a low-carbon steel in the blue heat range are inherent to that temperature and not duplicated when the same metal is tested at room temperature after a corresponding tempering. The actual results are shown by suitable curves and tables.—*Chemical and Metallurgical Engineering*, Jan. 17, 1923.

## Traction

*A 400-Hp. Swiss Motor Car.*—For a combination adhesion and cog-rail road of 3-ft. 3-in. gage a special motor car of the "D" type is described in this paper. The 40-ton car rests on two trucks of four wheels each, with one motor of 100 hp. driving each of the four shafts with double reduction gearing. On the grades of 20 per cent (cog-rail sections) a speed of 4.3 m.p.h. is obtained by operating the four direct-current motors in two groups in series, running at 460 r.p.m; on 7 per cent grades (adhesion sections) all four motors run in parallel at 1,160 r.p.m. The tractive effort is 8,800 lb. per pinion on the rack section and 3,400 lb. on the adhesion parts. Five independent brakes and a magnetic rail brake are provided on the car. One of them is governor-controlled and sets automatically if speed exceeds a permissible maximum. With a train of 57 tons weight an amount of heat of over 30,000 B.t.u. has to be dissipated in the resistances from current regenerated from the motors on the down-grade haul. Why this large amount of energy is not fed back into the line is not apparent from the paper. The emergency magnetic rail brake, with a magnetic pull of some 8,000 lb., can stop a train of 77 tons running at 7 m.p.h. on the 7 per cent section within 55 yd. —*Bulletin Oerlikon*, December, 1922.

*Electric Traction Developments in 1922.*—The most notable development in electric traction in the United States during the past year was the decision of the Illinois Central Railroad to adopt the 1,500-volt direct-current system with overhead trolley for the electrification of the Chicago terminal district. Other activities in this country were confined largely to equipment orders. Greater activity has been shown abroad, such as the extensive electrification by the South African government railway, the electrification of the harbor railway terminals in Montreal and various projects initiated in Japan, England, Sweden, Norway, Switzerland and France. — *Railway Electrical Engineering*, January, 1923.

## Telegraphy, Telephony, Radio and Signals

*Practical Alternating-Current Radio Receiving Tube.*—H. M. FREEMAN.—A new tube has been developed for radio service which may be used in ordinary receiving and amplifying circuits with alternating current on the filament. A general description of this tube is given.—*Electric Journal*, December, 1922.

*Telephone Repeaters.* — BANCROFT GHERARDI. — A description of the various types of telephone repeaters which have been designed and their operating characteristics is followed by an account of the application of the telephone repeater to the telephone art.—*Electrical Communications*, Vol. I, Nos. 1 and 2.

*Signaling Apparatus for Substations.* —P. KANNENGIESSER.—The commonly used optical or acoustical signal systems light a lamp or sound a horn in case trouble occurs such as the opening of a circuit breaker, the overheating of a transformer or the discontinuance of the flow of cooling water. On proceeding to remedy the trouble the attendant switches off the light or stops the noise of the horn, often forgetting to readjust these devices again so that they will be ready for the next trouble. The paper describes an alarm system which resets the device automatically.—*A. E. G. Mitteilungen*, December, 1922.

*Observations of the Field Strength of the Horsea (England) Wireless Station.* —E. B. MOULLIN. — Many measurements are recorded of the strength at Cambridge of the signals from Horsea during September, 1921, in which the Vallauri method of measurement was employed. The field strength is deduced from the measured electromotive force of the signal, the effective height of the receiving aërial being determined experimentally both from the distribution of current in the aërial up-lead and by comparing the receptive power of the aërial with that of a loop. Incidentally, the measurements of effective height provide a very accurate verification of the law that for short distances the electromotive force set up in an aërial is in direct proportion to the frequency of the incident waves. It was found that at a wave length of 3,000 m. the Horsea signals suffer an absorption of 40 per cent.—*Institution of (British) Electrical Engineers*, December, 1922.

# Scientific and Industrial Research

**A Department Devoted to Reports of Investigations Contemplated or Completed, Research Facilities Available and Suggestions for Co-operative Work**

*Conducted by* PROF. VLADIMIR KARAPETOFF, *Cornell University, Ithaca, N. Y.*

[PRINTED IN THE THIRD ISSUE OF EACH MONTH]

[When investigations which have been completed are, in the opinion of the editors, of wide enough interest to the field we serve, details thereof will be presented in other parts of this paper. Contemplated research or that which appears to have limited apppeal will be only briefly reported in this section, but details may be had by communicating with the investigator or institution named in the report. Readers are referred to the department "Digest of Electrical Literature" for investigations reported in other journals. The news and engineering sections should also be followed for research reported before technical societies.]

## Research Completed

### Bushing, Condenser Type, for 1,000,000 Volts.

The bushing for the one-million-volt transformer is more than 18 ft. high and weighs nearly 7 tons. The insulation consists of paper strip wound spirally on a 6-in. steel pipe. Layers of metal foil, also in strip form, serve to grade electrostatic stresses properly. The radial thickness of insulation is less than 18 in., and yet the bushing has been calculated to stand 2,000,000 volts for short intervals of time. Both ends are fitted with static shields in the form of torus rings, the upper one being 10 ft. in diameter. The part of the bushing in the air is surrounded by an insulating tube and the space filled with insulating gum.—*J. F. Peters and D. F. Miner, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.*

### Flash-Over Voltage, Effect of Surface Permittivity on.

Toepler has found (*Elektrotechnische Zeitschrift*, 1921, Vol. 42, page 1381) that under certain conditions the flash-over distance along a glass plate is proportional to the fourth power of the applied impulse voltage and to the 1.5th power of the capacitance of the plate per unit surface. To prevent flash-over the material of the plate must be of as low permittivity as possible and the thickness as great as possible, in order to reduce the flash-over distance with a given voltage. This relationship does not seem to be generally known and may prove to be useful in the design of high-voltage apparatus, especially for high frequencies.

### Friction Tape, Pinholes in.

Owing to imperfect impregnation, friction tapes often show pinholes, so that in cases where the tape is expected to have considerable insulating properties a sample should be held before a strong light to detect the presence of any great number of these holes. A maximum number of three holes is allowable per yard of tape, but a well-impregnated tape will usually have a much smaller number or none at all.—*Hydro-Electric Commission, Toronto, Ont.*

### Lighting, Direct Versus Indirect.

Experiments were made on twenty-six trained college seniors to determine the best intensity of illumination for reading. The average of the answers was 2.8 and 4.0 ft.-candles with the direct and indirect illumination respectively. It is thought that a greater intensity is needed with indirect lighting because the pupil of the eye contracts more because of the uniform illumination of the surrounding objects.—*William Kunerth, State College, Ames, Iowa.*

### Magnetic Field, Measurement of.

A two-electrode cylindrical tube is connected in multiple with a standard voltmeter and in series with a high resistance and a source of voltage. The tube is placed in the field and rotated until the voltmeter reading is a maximum. The direction of the field is then given by the direction of the axis of the tube, and its magnitude $H$ by the voltmeter reading $V$, according to the equation $H = (6.72/R)$ V, where $R$ is the radius of the anode. Fields from 20 to 500 gausses can be measured. By using a symmetrical tube and a polarizing field coil around it the range may be extended down to 0.1 gauss. *A. W. Hull, Research Laboratory, General Electric Company, Schenectady, N. Y.*

### Pyrometers.

A committee, with Dr. George K. Burgess as chairman, has devoted attention to improvements in pyrometry, including the measurement of the temperature of the bath of steel in open-hearth and electric steel-making processes. The industry cooperated in the experimental work. A symposium of fifty-seven papers was published in a separate volume by the American Institute of Mining and Metallurgical Engineers. This is considered the most important contribution to pyrometry since the invention of the Le Chatelier pyrometer.—*National Research Council, Engineering Division, New York City.*

### Transformer, 1,000,000-Volt.

A single-unit, 1,000-kva., 1,000,000-volt transformer for testing purposes has been built and tested. High-voltage coils are wound on concentric micarta tubes of increasing diameters and decreasing lengths. This automatically places the highest-voltage coil farthest from the grounded core. The distribution of stresses is similar to that in a condenser-type bushing. The coils on the two legs of the core are alternately connected in series to obtain a more uniform distribution of electrostatic field.—*J. F. Peters and D. F. Miner, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.*

### Wattmeter, Elimination of Correction for Phase Angle.

If both the current and the potential winding of a wattmeter are made of two sections which may be connected at will either in series or in parallel, two readings can be taken from which the correction for the phase angle in the potential winding can be eliminated. With this method more turns may be placed on the moving coil, making a more sensitive and robust instrument. Moreover, much more accurate readings can be obtained at low values of power factor and at high frequencies. For details see *Comptes Rendus*, 1922, Vol. 174, page 1007.—*H. Chaumot, Paris, France.*

[This method should be of interest in the measurement of dielectric losses.—EDITOR.]

### X-Ray Tubes, Crest Voltmeter for.

Of the crest voltmeters, of which the writer has made an extensive study, that of Fortescue, employing a condenser, a rotating commutator and a milliammeter at ground potential, is the only one found suitable for X-ray work. This meter, functioning directly, in the high-tension circuit, responds to every change in the secondary voltage due to any reason whatever.—*Munford Morrison, New York City.*

## Research in Progress

### Communication Over a 220-Kv. Transmission Line.

It is very essential that adequate and reliable communication be maintained between the larger generating and more important distribution centers. Where the distance of transmission is as great as it is to Pit River the investment in the ordinary metallic communication circuits runs into large sums. The ordinary wireless system of communication has many commercial disadvantages, but we hope, by the use of the wired wireless over our power circuits to establish, at a considerably lower cost, a system of communication that will materially reduce our investment.—*P. M. Downing, Pacific Gas & Electric Company, San Francisco, Cal.*

### Fuses, High-Tension, Repeating.

The writer is continuing to develop his system of high-tension repeating fuses for transformer stations and branch lines.—*L. M. Klauber, Consolidated Gas & Electric Company, San Diego, Cal.*

### Insulating Materials, Fundamental Study of.

A committee was organized under the chairmanship of Dr. F. B. Jewett, not for the purpose of developing new insulating materials nor to solve specific industrial problems, but rather to lay a foundation of fundamental knowledge of the phenomena on which solutions of practical problems can be based.—*National Research Council, Engineering Division, New York City.*

### Paints, Preservative.

We have under way an extensive series of tests, (a) to determine the lasting qualities of various pole and cross-arm paints; (b) to find the best pole preservatives, in particular for the protection of poles from white ants or termites; (c) we are making a study of paints and preservatives for general plant service, based on certain gas-plant residuals; (d) we are working on the perfection of the protective covering of steel pipe laid underground, particularly where corrosive soils are found.—*L. M. Klauber, Consolidated Gas & Electric Company, San Diego, Cal.*

### Sand, Inundated, Measurement of.

An investigation has been started to determine the feasibility of measuring sand for concrete in an inundated condition. With small additions of moisture, the quantity of sand in a given measure varies greatly with the amount of moisture. There is a reason to believe that with sufficient water in a measure to submerge the sand the quantity of sand becomes independent of the original moisture in it. A successful solution would insure uniformity in the proportioning of sand to cement and consequently uniformity in the strength of concrete. This is one of the most troublesome problems in the concrete industry—*Bureau of Standards, Washington, D. C.*

### Transmission at 220-Kv.

Our most important work is that in connection with the utilization of 220,000 volts for the transmission of power. This voltage being so much higher than any voltage ever before undertaken, its use involves a great deal of study and investigation.—*P. M. Downing, Pacific Gas & Electric Company, San Francisco, Cal.*

## Suggestions for Research

### Cables, Power Loss in Sheaths.

Sheath currents in single-conductor cables may reduce the carrying capacity of the cables by 10 or 15 per cent, the amount of the reduction depending upon the spacing of the cables, the thickness of the insulation and the size of the conductor. The losses in the lead sheaths must also be taken into consideration in calculating the efficiency of the transmission as they may be greater than the dielectric losses. The data heretofore published have been insufficient to make accurate calculations of these losses.—*A. I. E. E. Cable Research Committee.*

### Insulators, Pin-Type, Standardization of the Rating of.

A standardization of the rating of pin-type insulators on a basis of leakage distance, flashover and other physical characteristics, eliminating the nominal voltage rating, appears highly desirable.—*A. I. E. E. Committee on Transmission and Distribution.*

### Sphere Gap, Inaccuracy in Grounded.

In the *Journal* of the (British) *Institution of Electrical Engineers*, Vol. 57, page 223, Dr. Alexander Russell has pointed out certain discrepancies between the theoretical and observed values of the spark-over voltage when one of the spheres is grounded. A controversy between him and F. W. Peek, Jr., was published in the ELECTRICAL WORLD, Vol. 77, page 1427, and Vol. 78, page 469. The matter was not finally settled, and it would be of interest to perform the crucial experiments suggested by Russell at the end of his letter.

# News of the Industry

**Chronicle of Important Events and General Activities, Announcements and Reports of Association Meetings, Court Decisions and Commission Rulings and News of Electrical Men**

## Canadian Plant with Large Electric Boiler Load

Work has begun on a 120,000-hp. development on the St. Maurice River in the Province of Quebec, Canada. The project will be owned by the St. Maurice Power Company, which is closely allied with the Shawinigan Water & Power Company of Montreal. A bond issue of $10,000,000 has just been floated by the company on the property.

The hydro-electric plant will be located at La Gabelle, about 6 miles below Shawinigan Falls. It will operate under a head of approximately 65 ft. and is scheduled for completion about October, 1924. The dam across the St. Maurice River at La Gabelle will back the water up to the tailrace of the hydro-electric plants at Shawinigan and will have special gates for use in time of floods.

At first a general load of 30,000 hp. will be available, and the remainder of the power generated will be used in electric boilers for making steam, for which there is a great demand in the pulp and paper mills of the vicinity. It is anticipated that power for this purpose can be sold at from $9 to $10 a horsepower-year, depending on the price of coal. Such a rate, it is said, will be sufficient to carry the fixed charges on the installation until other load can be obtained. The advantage claimed for such a disposition of the power is that it enables the full development to be made at once, the electric boilers being used to absorb all the idle power available. The water turbines will be built by the Dominion Engineering Works, Ltd., of Montreal. The engineering is in charge of Julian C. Smith, Power Building, Montreal, Canada.

## Lightning-Arrester Committee Sees Steinmetz Tests

The lightning-arrester sub-committee of the protective devices committee of the American Institute of Electrical Engineers held a meeting on Feb. 12 at the Schenectady works of the General Electric Company, witnessing tests of arresters in the general engineering laboratory test department.

There was a demonstration in which the Steinmetz lightning generator was used. The tests were made to show the effects of high and low discharge rates in an arrester. This test and others involved a maximum of 120 kv. at about 5,000 amp. making use of the Steinmetz apparatus. Blocks of wood were split by the Steinmetz artificial "lightning" during the test. Protection tests for a 15,000-volt insulator were also held. These showed that when the insulator was protected by a high-discharge-rate arrester the lightning discharged through the arrester, but when a low-discharge-rate arrester was used a flashover occurred. Another test showed the difference between testing lightning arresters with a high-frequency oscillator at the same voltage but rated at only about 0.75 amp. and testing them with the Steinmetz generator, the effect on different types of insulation being noted.

## State Chamber of Commerce Opposes Smith's Policy

Delegation to municipal bodies of the regulative powers over public utilities now exercised by the state, as proposed by Governor Smith of New York, is characterized as "reactionary" and a "retrogressive step opposed to the best interests of the people" in a report of a committee on public service approved by the Chamber of Commerce of New York State. The report points to nation-wide investments in public service enterprises in New York State aggregating a billion dollars. These investments, it says, were made in reliance on a system of just and impartial state regulation, and a return to old conditions would be a breach of faith and render it difficult for the utilities to raise new capital.

## New York State Commission Legislation Delayed

Following the introduction of the transportation bill favored by Mayor Hylan of New York, which aims to abolish the present Transit Commission appointed by Governor Miller for that city and substitute a Transportation Board appointed by the Mayor and controlled by the city's Board of Estimate, the main public utility commission bill of the new state administration was, according to announcement from Albany, to have been introduced into the Legislature on Wednesday of this week. After the bill was prepared, however, it was withheld for further conference, and it had not made its appearance up to the time the ELECTRICAL WORLD went to press.

This bill, as previously told in these pages, will aim to restore "home rule" in the control of utilities contained within city limits to all the cities of the state, permitting them to set up new governing bodies for this purpose, to utilize municipal bodies already existing, or, if they should so elect, to leave control with the state commission.

## Awards Under Coffin Foundation Soon to Be Made

Frank W. Smith, as president of the National Electric Light Association and chairman of the Charles A. Coffin prize committee of that body, has issued a letter to all central-station companies in the country inviting them to participate in the awards to be made under the terms of the Coffin Foundation as established by the General Electric Company and announcing further details. He says:

"The announcement, in so far as it refers to the central-station industry, is broadly interpreted by the committee as providing for the annual award of the Charles A. Coffin medal to the public utility operating company within the United States which during the year has made the greatest contribution to the development of the general use of electric light and power by the public and to the benefit of the industry.

"Every electric light and power company in the United States is invited to participate and urged to send to the undersigned committee a presentation of its activities and accomplishments covered by the field of the award.

"The committee suggests that among the factors which will be considered in making the award are the following: The particular initiative, skill and enterprise which have been manifested in popularizing the general use of electrical energy; accomplishments in the development of the efficiency of your organization, improvements in construction practice which have resulted in greater reliability of service, marked increases in the efficiency of generation and distribution, the adoption of special plans which have resulted in the largest percentage of increase in new customers, methods adopted of interesting customers in stock ownership, unusual efforts and accomplishments in popularizing and introducing domestic appliances, and extension of service to homes not previously wired and to rural communities.

"The first award of both the medal and the thousand dollars for the central-station company's employees' benefit fund will be made in the year 1923. The announcement of this award will be made at the annual convention of the N. E. L. A. in New York City, June 4 to 8.

"All statements must be in the hands of the committee by March 15. Kindly address these to the Charles A. Coffin Prize Committee of the National Electric Light Association at 130 East Fifteenth Street, New York City."

# A. I. E. E. Holds Two-City Meeting

**Chicago and New York Listen to Same Addresses Carried by Long-Distance Telephony—Large Attendance at Midwinter Convention in New York from All Parts of the Country**

WITH a surprisingly large attendance of members—approximately seven hundred had registered up to Thursday noon—from all portions of the United States, the American Institute of Electrical Engineers held a most successful and active midwinter convention at the Engineering Societies Bulding in New York this week. One of the outstanding features of the gathering was the joint session with Chicago on Wednesday evening, when two-way loud-speaking telephone installations were used at each city so that the two audiences, separated nine hundred miles, heard all the proceedings of the joint meeting. In addition, everything that was said at either end of the line was broadcasted. One thousand persons were present at the divided meeting.

At the various sessions of the convention papers of the high caliber usual at Institute meetings were presented according to a prearranged schedule, which allowed ample time for discussion. The smoker on Thursday evening and the annual dinner-dance on Friday evening were well attended and scored the customary success. The usual number of inspection trips were arranged for delegates and guests during and after the convention. Among these trips was one to the offices and plant of the McGraw-Hill Company, publisher of the ELECTRICAL WORLD and other technical papers, where delegates to the convention were entertained at luncheon on Thursday noon. Visits to New York power houses and telephone and broadcasting exchanges of the American Telephone & Telegraph Company were some of the other trips.

### PRESIDENT JEWETT'S ADDRESS

In opening the convention President Frank B. Jewett paid tribute to the ever-increasing effectiveness of electricity in the service of mankind. The extensive technical program of this convention, he said, was an example of the return to highly technical subjects in the last few years. This may be due to the necessary restriction of technical research and development during the war to certain channels, or it may be due to the opening of new fields to electrical application. In the communication field the great activity, the speaker thought, was chiefly due to the intense popular interest in radio.

Elaborating on the latter topic at Wednesday night's session, Mr. Jewett said in part: "We can hardly picture the limits of the effects and influences which will flow from the developments of electric science which have made this night possible. In truth, we are participants in a historical event and our children, nay even many of us, may see the agency we here use employed with mighty effects in controlling our collective relations in state and nation.

"Some one has said that the greatest political engine ever devised was the colonial town meeting, where every question of importance was debated and discussed in the open forum of all the citizens. Be that as it may, we are well aware that our best government today is found in those small political units where the town meeting in some form is feasible and still persists. It is only when we come to the larger units of city, state and nation that the limitations of common discussion of vital matters, which are imposed by sheer physical size, evidence themselves in cumbersome and inadequate substitutes for personal discussion and ofttimes in unsatisfactory results.

"May it not be that in this two-way working telephone, with its sensitive transmitters and loud-speaking receivers, we have the instrumentality for insuring a simpler and better ordering of our affairs—an instrumentality which will enable us to derive many of the benefits of the town meeting in the greater concerns of our national life? The mechanism which we are here using is one adapted to permit many speakers in many distant audiences to be heard by all who care to listen and take part in a common discussion.

"In voicing the opinion that this mechanism is destined profoundly to affect our political and economic machinery, I intend to convey no thought or picture of a pure democracy, but only of a representative form of government in which all questions that would be helped by oral discussion can be so discussed without restraint from the physical limitations of the human voice or of distance. They might be discussions between widely separated groups on some matter of common concern or between a designated representative and his constituents. We have here the successful realization of a dream dating back to the pioneer days of Bell himself, namely, the production of a loud-speaking telephone which would reproduce the human voice in stentorian tones and in many places simultaneously.

### ONLY DISTANT VISION LACKING

"We lack only direct distant vision to make this joint meeting one in very fact save only for the element of the personal proximity of those in attendance, and who among us is hardy enough to believe that this last limitation may not be removed within the lifetime of many of those now here?

"Fundamental and applied research are opening new doors daily in bewildering succession. When they open that last door which now prevents man from exercising at a distance all of his powers of personal intimate communication we will have another noteworthy meeting of this Institute.

"Tonight, however, we must be content with full powers of speech and hearing but with partially defective vision. So it comes about that you, Mr. Schuchardt, our vice-president in Chicago, and you, Mr. Rhodes, my vice-chairman, are each in a unique position, a position in which one of you is acting in place of the president at a meeting where the president himself is in attendance in his official capacity, and the other is acting similarly for the president in his capacity as presiding officer. Some day this may not be necessary, but for the moment we are really acting as the eyes of this great joint meeting and are transferring as best we can the functions of distant vision by means of human speech."

### TECHNICAL POINTS EXPLAINED

The technical aspects of the loud-speaking telephone were discussed in a paper by I. W. Green of the American Telephone & Telegraph Company and J. P. Maxfield of the Western Electric Company, who stated that the amplifying apparatus used last night was powerful enough to reach an audience of seven hundred thousand persons and that the electric power used by the loud-speaking telephones would be sufficient to operate all of the fourteen million telephone instruments in the country.

A second paper by W. H. Martin and A. B. Clark, read in Chicago, described the problem involved in attaching the loud speaker to long-distance telephone circuits. Both papers were discussed simultaneously before two audiences by J. J. Carty, vice-president of the American Telephone & Telegraph Company, speaking in New York, and B. E. Sunny, chairman of the board of directors of the Illinois Bell Telephone Company, speaking in Chicago.

After the discussion of these two papers W. B. Potter of the General Electric Company presented his observations on electric railway practice in Europe. This paper included a comparison of American and European rolling stock. He also gave a comprehensive description of the various methods of locomotive drive used in Europe, illustrating them with numerous slides. M. Le Blanc, a visiting French railway engineer, discussed this paper.

Reports of the six technical sessions of the convention will be presented at considerable length in next week's issue of the ELECTRICAL WORLD.

## Spring Convention of Institute at Pittsburgh

The spring convention committee of the American Institute of Electrical Engineers, in connection with the meetings and papers committee, has fixed the date of the Pittsburgh meeting as April 24-26. The headquarters will be at the William Penn Hotel. On the first day there will be afternoon and evening technical sessions, on the second day a technical session under the auspices of the protective-device committee in the morning and a visit to the Westinghouse plant at East Pittsburgh in the afternoon, and on the third day a morning program under the auspices of the electrochemical and

electrometallurgical committees and an afternoon session dealing with radio at which there will be papers presented on the applications of wireless to power transmission.

For the annual convention of the Institute, to be held at Swampscott, Mass., June 25-29, tentative plans are being formed by the committees in charge.

The Pacific Coast men have already prepared their program for the Del Monte convention on Sept. 25-28, as announced in the ELECTRICAL WORLD for Feb. 3, page 293.

## House Pursues Subject of Radio Monopoly

As an outcome of the discussion by the House of Representatives of the alleged monopoly of radio transmission by four large companies (see ELECTRICAL WORLD for Feb. 10, page 350), Representative White of Maine has introduced a resolution calling for investigation by the Federal Trade Commission of ownership and control of patents for the manufacture of radio apparatus, contracts or agreements for the sale or use of such apparatus tending to restrict or to fix prices, and agreements tending to give exclusive rights or special privileges in transmission or reception of radio messages.

The resolution has been referred to the committee on merchant marine and fisheries, which is favorable to it, and it is expected that it will be adopted by the House. Concurrence by the Senate would not be necessary.

## Federation Urges Leadership by Engineers

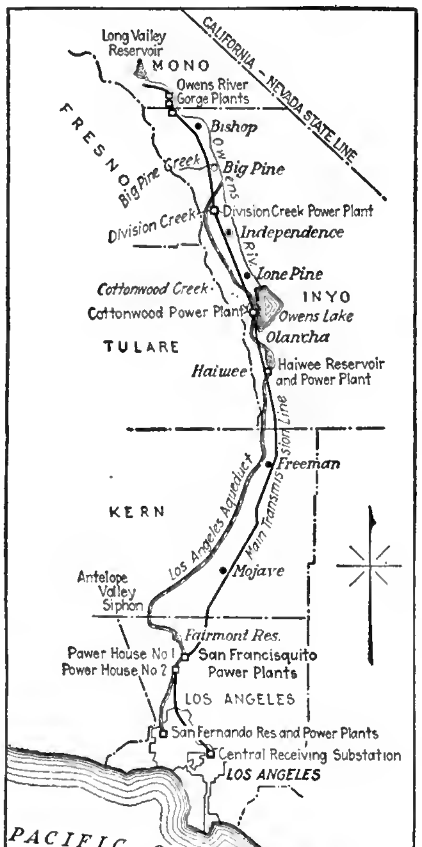
"For a century," declares the committee on industrial ideals appointed by the Federated American Engineering Societies, in a report recently submitted to the federation, "engineers have directed their energy toward the utilization of the physical forces and the materials of nature. The developments which they have brought about have created an epoch in human history. While these developments have been of inestimable benefit and modern society could not exist without them, they have introduced many public problems and social readjustments so closely related to the engineer's activities that it is increasingly evident he must assume an active part in their solution.

"Recognizing this growing need, the engineers of the country formed the Federated American Engineering Societies, primarily to place their knowledge and training at the public service on all public matters affecting engineering or affected by it. The Federated American Engineering Societies, therefore, speaking for the engineering profession, urges upon engineering colleges an increased attention to the social aspects of engineering activities and a broadening of their technical training in every way possible, to develop in engineering students the spirit of and a capacity for active leadership, not only in industry but in public affairs."

Prof. Joseph W. Roe, head of the department of industrial engineering at New York University, is the head of the committee on industrial ideals, of which the other members are Dean Cooley, Prof. C. F. Scott of Yale and J. C. Ralston of Spokane, Wash.

## Outline Map of Los Angeles' Proposed System

The map below indicates the territory to be covered by the hydro-electric system planned by the city of Los Angeles. The ultimate output to be delivered to the city from these developments is put at 205,000 hp., 105,000 hp. coming



from San Francisquito plants Nos. 1 and 2 and 100,000 hp. from all other plants. Further details are covered in the following tabulation:

| | Francisquito No. 1 | Francisquito No. 2 |
|---|---|---|
| Gross head, ft.......... | 943 | 562 |
| Maximum flow, sec.-ft... | 1,000 | 1,000 |
| Average flow, sec.-ft.... | 400 | 400 |
| Output at switchboard (at 1,000 sec.-ft. flow), hp. | 69,000 | 44,000 |
| Generating units, number. | 6 | 3 |
| Generating units, size hp. | 12,500 | 18,500 |

## Washington State Now Has Information Committee

Organization at Seattle of the Washington Committee on Public Utility Information has been announced, with E. H. Thomas, until recently publicity representative of the Puget Sound Power & Light Company, as director. The following utility companies are backing the new committee: Puget Sound Power & Light Company, Pacific Power & Light Company, Portland Railway, Light & Power Company, Grays Harbor Railway & Light Company, North Pacific Public Service Company, Olympia Light & Power Company, Stevens County Light & Power Company, and a number of other smaller companies.

In announcing its formation Mr. Thomas said:

"The purpose of the committee is to promote better relations between the utilities and their customers and to give the public such information as they may desire regarding the utilities and their organization and operation.

"Weekly bulletins to the press of the state will be one of the methods employed to give out information, but not the only one. We offer our services to interested patrons and citizens, and particularly to the newspapers, as an information bureau."

## Another Indiana Utility Commission Bill

The latest bill to be introduced in the Indiana General Assembly to curtail the authority of the Public Service Commission would permit municipal corporations to establish utilities when privately owned utilities providing the same service already exist without asking the commission for permission. This bill does not mention the fixing of rates, leaving that to the commission. A bill introduced previously along the same lines permitted the municipalities to fix rates also without interference from the commission.

## Underwood Seeks Action on Ford Proposals

With all the probabilities strongly against his success, Senator Underwood of Alabama, the Democratic leader of the Senate, is contending in the upper house that since Henry Ford's bid for Muscle Shoals was submitted as a result of a formal request from the government it should be accepted or rejected by this Congress. Business ethics, the Senator holds, demand that when bids are invited the bidders shall be told whether their proposals are accepted or rejected. He characterized the long-delayed action on the Ford offer as a cavalier way in which to treat any bidder.

Senator Underwood called attention to the fact that there no longer is any controversy about the completion of the Wilson Dam since each house has authorized the engineers to make the final contract for its completion. He pointed out that within three years at most a great electric plant will be ready for operation at Muscle Shoals, saying that the issue before Congress is whether it is to be operated by private effort or as a government institution.

The debate in the Senate was brought about by an amendment proposed by Senator Norris suggesting an appropriation of $2,000,000 for the installation of new machinery in Nitrate Plant No. 1, so that the plant could be used for experimental purposes. Senator Norris argued that such a proposal should not be objectionable to Mr. Ford since he

would have to conduct such experiments if his offer were accepted. The amendment was opposed on the ground that it would complicate the situation by additional expenditures, experimentation and contracts. The trend of the debate made it clear to Senator Norris that the amendment could not prevail, and he withdrew it.

## Defenders of Water-Power Act Attack Ford Plan

Herbert Knox Smith, Commissioner of Corporations under Presidents Roosevelt and Taft, and Philip P. Wells, secretary of the National Committee for Defense of the Federal Water-Power Act, have launched a broadside attack upon the Ford Muscle Shoals offer in a letter and pamphlet sent to members of the Senate and House of Representatives.

The letter, written by Mr. Wells, summarizes the arguments against the legislation favored by Mr. Ford's supporters as follows:

"The real vice of this scheme is not in the present money loss. Its real vice is that it smashes straight through the vital principles of the federal water-power act for the protection of the public.

"(1) It is a grant for one hundred years.

"(2) It provides for no rental payments whatsoever for the use of the site and only an absurdly small rental for the use of the works built with government money.

"(3) There is no provision whatsoever to prevent the making of excessive profits on the Ford company's actual investment nor to require any transfer of such excess to the public.

"(4) There is no regulation whatsoever of the distribution or use of the power.

"(5) There is no provision that it shall be used for public service.

"(6) The Ford company is not required in any way to contribute to the cost of storage reservoirs hereafter built upstream. Such reservoirs would enormously increase the value of the Ford company's site, and the government is now making a survey for such storage development."

With Mr. Wells' letter is inclosed a pamphlet by Mr. Smith bearing the title "Preserve the Federal Water-Power Act." In this pamphlet Mr. Smith does not mince his words. "Flagrant violation," "extraordinary special privilege" and "national insanity" are among the terms he applies to the Ford proposal.

## Electric Heat Exhibit in Edison Showrooms

The second of the series of special electrical exhibits which the New York Edison Company has scheduled for its Irving Place showroom will show the domestic, industrial and commercial uses of electric heat and will be held during the week of Feb. 19-24. Twenty-one manufacturers will exhibit.

## Electrical Supply Jobbers Discuss Competition

The future of the electrical supply jobbers' business, the value of their association and a talk on federal income taxes were the chief features of the two-day session of the Central Division of the Electrical Supply Jobbers' Association held at the Hotel Sherman, Chicago, this week.

Discussing the future of the business, N. G. Harvey, Chicago, felt that the change throughout the country in central-station sentiment toward jobbers would help in solving many jobbing problems. With these cordial relationships, together with the increase of building, he thought that the supply business during 1923 would be on the up grade.

F. D. Vanwinkle, Cincinnati, cited figures which showed that more houses were wired in his territory during the past two years than in the previous thirty. With an operating jobbing expense in 1922 of 17 per cent, Mr. Vanwinkle failed to see how it was possible to reduce his expense any lower for two reasons, first, because each item of this expense had been cut to the bone and, second, because salaries and materials would be higher in 1923.

The subject of competition was warmly discussed by W. R. Herstein, W. W. Low, H. F. Thomas, C. J. Litscher and Harry Downing. The general sentiment was opposed to price cutting, although competition sometimes played havoc with legitimate profit. Regarding compensation of salesmen, W. W. Low, Chicago, thought that a percentage of profit would be more beneficial to both the jobber and his salesmen than one on sales volume.

P. Oblinger, Indianapolis, declared that the jobbing business was here to stay, but that with each house it would be a case of survival of the fittest.

## O. E. L. A. New-Business Meeting

The new-business co-operations committee of the Ohio Electric Light Association will meet at the Deshler Hotel, Columbus, on Wednesday next, Feb. 21. Prof. H. B. Dates, Case School of Applied Science, will speak in the morning on "Public School Lighting," and Prof. F. C. Caldwell, Ohio State University, will lead a discussion on this subject.

Dr. M. Luckiesh is to present a paper on "Modern Lighting" during the afternoon session, which will be discussed by S. G. Hibben and J. B. Wilson. "Recent Progress in Rural Service" will be treated by D. L. Gaskill, secretary of the association.

# Commonwealth Edison's Newest Station

### Crawford Avenue Will Have Ultimate Rating of 400,000 Kw., if Not of 600,000 Kw.—Construction Begun and First Unit Will Probably Be Ready in Eighteen Months

FURTHER construction plans for its new South Crawford Avenue plant have been announced by the Commonwealth Edison Company of Chicago. The second generating unit of this 400,000-kw. station will have a rating of 50,000 kw. and will be manufactured by the Westinghouse Electric & Manufacturing Company. Like the 40,000-kw. Parsons unit, which was announced in the January 20 issue of the ELECTRICAL WORLD, this unit will have a high-and-low-pressure compound section. The third unit, not yet ordered, will be supplied by another American manufacturer.

Construction work on this site, on the east side of Crawford Avenue, extending south from West Thirty-third Street to the Drainage Canal, has been started, and the first generating unit will, it is expected, be in operation in August, 1924. Storage space for about 300,000 tons of coal is provided by the 72-acre plot.

With the station planned for ten units of from 40,000 kw. to 60,000 kw. each, the ultimate capacity will not be less than 400,000 kw. and, when finally completed, it may be around 600,000 kw. The main turbine hall will be 800 ft. long and 125 ft. wide. Five smokestacks in the completed station will extend 175 ft. above the boiler-room floor. They will be of steel and are to taper from the bottom to the top, with an inside diameter of 19 ft. Two rows of five boilers each will be connected to one stack. Since five boilers will provide steam for one unit, the total number of boilers in the entire plant will be fifty. These boilers are to operate at a steam pressure of 550 lb., giving a total steam temperature of 725 deg. F. Ample water facilities for condensing purposes will be obtained from the Drainage Canal, which comes from Lake Michigan.

This Crawford Avenue station will constitute the fourth great power-producing center of Chicago. To provide continuity of service the new station will be tied in by four 33,000-volt underground cables to the Calumet station, by two underground cables to Quarry and Fisk Streets and by two cables to the Northwest station. These tie lines will terminate at Crawford Avenue in an outdoor switching center.

The consulting engineers for the Crawford Avenue station are Sargent & Lundy, Chicago, while Merz & McLellan of London are acting in an advisory capacity on Unit No. 1. The engineering department of the Commonwealth Edison Company is handling the electrical features. Graham, Anderson, Probst & White are the architects.

## Death of Röntgen

**Famous Discoverer of X-Rays Dies at His Home in Munich in His Seventy-eighth Year**

THE discoverer of the X-Rays, Wilhelm Konrad Röntgen, died at his home in Munich on Saturday, Feb. 10, at the age of seventy-seven. He was born in Lennep, in the Ruhr district of Germany.

The discovery of the X-rays dates back to 1895. Many before Röntgen, while discharging electricity through vacuum tubes or highly exhausted tubes in the study of the action of electricity on gas, had produced X-rays without becoming aware of their presence. In this kind of experiment Sir William Crookes had developed the Crookes tube, but he did not detect the fact that this tube produced rays which penetrated matter and made it possible to see through solids. This discovery was left for the German scientist. When he announced it the X-rays were looked on as some new manifestation of energy. It has since been shown that they differ from ordinary light only in wave length. Visible light is of the order of a fifty-thousandth part of an inch in wave length while the X-rays have to be described in millionth and billionth parts of an inch.

Dr. Röntgen was fifty years old when he made his discovery. He received his early education in Holland and then went to study at Zurich, where he took his doctor's degree in 1869. He was director of the Physical Institute at Wurzburg when he discovered the X-rays. In 1900 Columbia University awarded him the Barnard medal for the greatest discovery in science of the previous five years. In 1901 he received the Nobel prize for physics. He received the Rumford medal of the Royal Society in London in 1896, jointly with Philip Lenard, who had conducted researches in the same subject.

## Brooklyn Edison Company Has Prosperous Year

The annual report of the Brooklyn Edison Company for the year ended Dec. 31, 1922, shows substantial increases in gross and net revenues over the previous year. The net income was $4,105,407, as compared with $2,772,420 the year before, and surplus for the year, after deducting dividends, contingency reserves and other charges, amounted to $972,364, against $255,-074.

A feature of the report was the increase in the holdings of stock by employees. The investment fund set up by the company in the interest of employees retains 8,795 shares of stock for the benefit of 2,757 employees, and in addition 454 employees hold individually 6,000 shares, making total holdings of 14,795 shares by employees, an increase of 300 per cent since 1916.

"The year was the most progressive in the company's history," President Sloan said in his statement. "During the year the company sold 381,232,300 kw.-hr., an increase of 55,467,782 kw.-hr. over the preceding year. New meters installed totaled 63,657, and power contracts for 60,000 hp., an excess of more than 50 per cent over the previous year, were secured. There were built and connected to the existing system 31 miles operating at 13,200 volts, 19 miles at 6,600 volts, and in addition 888 miles of distribution feeders and mains."

## Hartford Offers New Heating and Lighting Rate

Another two-part rate has been established recently by the Hartford (Conn.) Electric Light Company in connection with residential service, the new schedule being optional and available only for private household use, for lighting and the usual small domestic appliances in conjunction with an electric range and large water or air heaters. All ranges, heaters, etc., used on this schedule are subject to the approval of the company as to size and types, and the customer is required to arrange wiring for one or more meters as directed by the company, the readings of all meters being added together for billing purposes. Customers using this schedule guarantee an annual payment for energy of not less than 300 kw.-hr. for each kilowatt of apparatus charged for in the flat-rate portion of the schedule.

The schedule is as follows: (1) Flat rate, payable monthly, with (a) $1.44 per year per 100 sq.ft. of floor area plus (b) $24 per year for the first 4 kw. (or any part) and $4 for each additional whole kilowatt of installed load of range and each kilowatt of large water or air heater (minimum kw.), plus (2) energy at 2 cents per kilowatt-hour. The rate carries the coal clause applying to the company's power rates.

# Many Projects Before Power Board

**Spawning Grounds for Fish Prevent Erection of Dams in Alaskan Streams—Licenses Granted in National Forests—Damage Clauses Outside Commission's Jurisdiction**

NO LICENSES are to be granted by the Federal Power Commission for power projects on Anan Creek and the Kenai River in Alaska because it is held that high dams in these streams would result in damages to the fish industry entirely out of proportion to the value of the streams as power producers. Preliminary permits subject to the approval of the Bureau of Fisheries had been granted. Frank L. Bellain of Seward was the applicant for the Kenai River site, which was to have been used to furnish power for pulp and paper manufacture, and the Anan permit had been issued to the Alaskan Mine & Development Company, a Guggenheim interest. In each case, the commission believes, the applicants will be able to find equally desirable sites where dams would not interfere with spawning grounds.

A preliminary permit has been authorized, in accordance with the application of Frank I. Reed of Anchorage, Alaska, covering a power project on the Eklutna River, near Anchorage.

Favorable action was taken on the application of the Mokelumne River Power & Water Company of San Francisco for a preliminary permit covering a combined power and irrigation project on the South and Middle Forks of the Mokelumne River and the North Fork of the Calaveras River.

An extension of one year in the time limit of the preliminary permit of the Lower Niagara River Power & Water Supply Company of New York has been granted by the commission. The company received a preliminary permit on March 3, 1921, for a period of two years.

The preliminary permit of Mushen & Cronemiller of Lakeview, Ore., has been extended one year from May 25, 1923.

The preliminary permit of the Louisiana Gravity Canal Company of Alexandria, La., which was issued on Jan. 4, 1922, for a period of fifteen months, has been extended for a period of twenty-one months.

The preliminary permit issued R. G. McDonald of Williams, Cal., on June 15, 1922, covering a project on Convict Creek has been revoked on the ground that he has failed to carry out the engineering investigations and the stream gaging required.

A license covering the Narrows unit of the Ouachita River project of the Caddo River Power & Irrigation Company has been issued. The company, which has its domicile at Little Rock, Ark., holds a license covering two more important sites on the Ouachita, but has decided to begin with the smaller projects at the Narrows site, 11 miles below the others.

### Licenses in National Forests

Two transmission lines owned by the Summit Power Company of Denver have been licensed by the commission. The lines cross the Leadville National Forest. A license was authorized for the Nevada-California Power Company of Riverside, Cal., covering a transmission line in the Inyo National Forest, which will connect the company's Bishop Creek plant to the trunk line of the Southern Sierras Power Company. A license also was authorized covering a transmission line in the Whitman National Forest, to be used by the Beaver Gold Mining Company of Portland, Ore. A license was also issued to A. E. Humphreys of Denver covering a 15-hp. project in the Rio

Grande National Forest. Permission was given the Virginia-Western Power Company to overflow a few acres of the Natural Bridge National Forest at Balcony Falls, on the James River, Va.

The commission has authorized an amendment to the license issued the Utah Power & Light Company for its Soda Point project on the Bear River in Idaho which will permit it to relocate its dam and power house 1,200 ft. upstream to avoid leaking bedrock.

Formal protests have been filed with the commission by the Tennessee municipalities of Bristol and Bluff City and by the County of Sullivan against the application of the Holston River Power Company, covering three sites on the Holston River. The protest discloses that public development of that stream is in contemplation.

In response to a letter from Governor Hunt of Arizona urging prompt action on the Girand application for a license at Diamond Creek on the Colorado River, the commission has replied that action in the matter will be withheld pending the disposition to be made of the Colorado River compact.

The development of hydro-electric power in the vicinity of Louisville has been further complicated by the entry upon the scene of Indianapolis interests, which have filed a declaration of intention covering power development on the Cumberland River.

#### DAMAGES OUTSIDE COMMISSION'S SCOPE

The Salt River Valley Water Users' Association has been given to understand by the Federal Power Commission that it will not hold up development on grounds such as have been put forward by that association against the application of F. G. Baum for a preliminary permit covering a project on Black River. Were the commission to accede to the wishes of the Water Users' Association, it is held, the development of 6,000 square miles in the drainage area above the Roosevelt Dam would be stopped. Neither will the commission insert conditions as to damages. The whole question of damages, it is held, is outside its jurisdiction.

The board of regents of the University of Minnesota has formally petitioned the commission to issue no license covering the High Dam in the Mississippi unless it contain a provision that the university is to receive the revenue accruing from 15 per cent of the power sold and be safeguarded in the use of whatever volume of water it may require for hydraulic experiments.

Representatives of the States of Washington, Idaho and Montana, and of the Montana Power Company, have been invited by the executive secretary of the commission to appear before him on March 15 in connection with the Flathead Lake development proposed by the Rocky Mountain Power Company. The principal question involved is whether or not the power company should make full development of the storage or whether the Washington State authorities should be allowed to develop a part of it.

## Big Program in Ohio

**Electric Utilities Planning to Spend About $75,000,000 in the Next Three or Four Years**

A TENTATIVE program involving the expenditure in Ohio of more than $75,000,000 in the next three or four years for additional facilities in the generation and distribution of electricity is now under way. This program, part of which will be actually carried out this year, involves the establishment of a state superpower zone system that will link together most of the great central stations. Virtually every large city in the state will be affected. Lack of water for condensation purposes, particularly in the central part of the state, has been a large factor in leading to the superpower project.

Before the end of 1923 physical interconnection between the properties of the Cleveland Electric Illuminating Company, the Northern Ohio Traction & Light Company and the American Gas & Electric Company, operating through its subsidiary, the Ohio Power Company, will, it is thought, become an accomplished fact. Actual construction on this project is now well under way, as is also another interconnection that will link with this power zone the properties of the Ohio Public Service Company, already tied in through the Lake Shore Electric Railway Company with the generating plants of the Toledo Edison Company. This means that by fall a superpower system for the entire eastern half of the state and that whole portion lying along Lake Erie from Cleveland to Toledo will have been built.

#### SOUTHERN OHIO COMPANIES TO COME IN

In addition to this, engineers have begun calculations to determine how the properties of the Union Gas & Electric Company at Cincinnati may be "hooked up" to carry current up the state as far as Columbus. In this scheme is involved the problem of linking in the Dayton Power & Light Company, which serves many towns in the southwestern part of the state, and the Consolidated Light, Heat & Power Company of Huntington, W. Va., which serves communities in the southeastern part of Ohio as well as in West Virginia.

The superpower system for Ohio involves the expenditure not only of many millions for new generating stations but also of many additional millions for high-tension transmission lines. The maximum capacity of these lines for the present will be 132,000 volts, but before the entire development is completed this maximum will probably be increased in some instances to 220,000 volts.

Construction work under way this year in the building of new generating plants at Cleveland, Zanesville, Steubenville, Windsor and Beach Bottom, W. Va., together with high-tension transmission lines, involves a new capital investment of approximately $40,000,000 and means that the customers on the lines of the Cleveland Electric Illuminating Company, the Northern Ohio Traction & Light Company, the Pennsylvania-Ohio Electric Company, the Ohio Public Service Company and the American Gas & Electric Company, through its subsidiary, the Ohio Power Company, will be assured of adequate and uninterrupted service.

## New Transmission Line from Cleveland to Akron

Contract for a 132,000-volt transmission line to tie in the Cleveland Electric Illuminating Company with the Northern Ohio Traction & Light Company at Akron, Ohio, has been awarded. This undertaking involves an expenditure of approximately $750,000. The Cleveland company will construct the line as far as the southern boundary of Cuyahoga County. From that point to the South Akron substation the Northern Ohio will build the line. An addition is to be built to this substation which will include new transformers. At this point the high-tension line from Windsor, W. Va., ties in, giving the Ohio utility three sources of supply. The power demand upon the Northern Ohio Traction & Light Company is now almost up to the capacity of the Gorge plant and the supply from Windsor; but this new supply from Cleveland is bringing 25,000 kw. and will aid future development of Akron as well as provide a strong reserve for the needs of the future.

Steel towers 86 ft. high will be designed to provide for two circuits, although only one will be completed at the present time. The Akron load demand in 1915 was 16,500 kw. In 1922 it had risen to 45,000 kw., with an output of 232,000,000 kw.-hr.

## Nation-Wide Farm Radio Service Completed

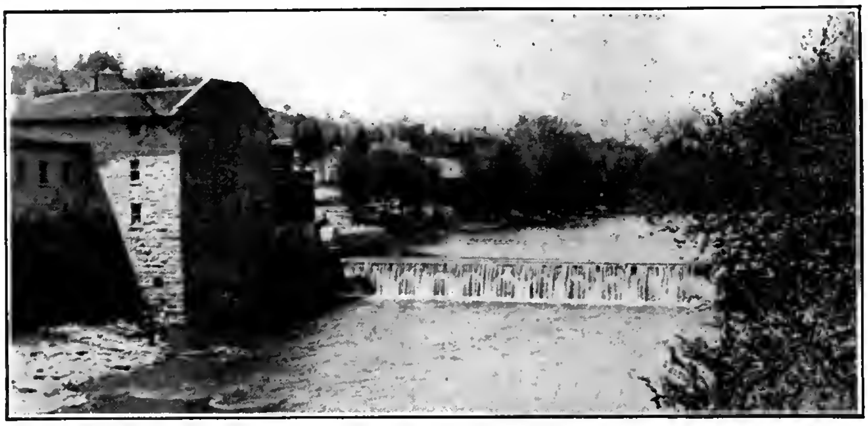
Completion of a radio communication service covering the entire United States has just been announced by the Department of Agriculture. The service includes market reports, weather information and crop data and insurance against losses due to unexpected storms. The service employs four high-power radio-telegraph stations of the Navy Department, five radio-telegraph and one radio-telephone installation of the Post Office Department and seventy-eight radio-telephone stations belonging to agricultural colleges, electric light and power companies, newspapers and other owners.

It is now possible, it is declared, to communicate with farmers in every section of the country, warn them of the approach of storms, advise them of the proper time to move produce so as to avoid flooding the market, and at all times keep them posted on agricultural topics of interest long before the news could reach them in the ways through which it has hitherto come.

## From Mill to Power House

**How a Hydro-Electric System Has Superseded Oldtime Hydraulic Plant in Iowa**

THE People's Electric Service Company of Elkader, Iowa, which has just been incorporated with a capitalization of $750,000 to succeed the Turkey River Power Company, affords an interesting example of a central-station system which has grown up on the site and in the territory of an oldtime gristmill. Its hydro-electric system is about fourteen years old and its construction began when a flower and feed mill which had utilized the waters of the Turkey River ever since 1849 was finally discontinued. The old mill had in its prime been one of the most important in the upper Mississippi Valley, shipping flour up and down the Mississippi. With the decadence of its business the proprietors, the Schmidt Brothers, turned their attention to hydro-electric power. Using the mill, built of rock from the river bluffs, as a power house and starting with a plant just big enough to supply Elkader, they gradually increased its capacity and extended their lines until at present there are thirty or more towns on the company's circuit and its high-tension lines run into four Iowa counties. A modern concrete dam has supplanted the old rock and log structure, and the interior of the mill is now being remodeled, the part formerly used for a flour storeroom being made over into a workroom, a storeroom for electrical supplies and an office and display room for fixtures and accessories. The company is now planning to reclaim another millsite on the Turkey River, south of Elkader, where a big four-story mill still stands, though it has long since ceased to grind and the dam has for the most part disappeared.



IOWA CENTRAL-STATION PLANT INSTALLED IN OLD MILL

## Oklahoma Operators Studying Combustion

A class in the combustion of fuel has been started by the city division of the Oklahoma Gas & Electric Company. L. C. Lichty, professor of mechanical engineering, University of Oklahoma, is conducting the course, which was worked out by J. F. Owens, vice-president and general manager; E. E. Hunter, superintendent of power plants, and W. J. Brown, chief engineer. The company bears half the expense and thus far forty-five men have enrolled. This class has been organized in fulfillment of the company's policy of establishing classes for its employees in various departments. Other classes are running in other divisions. The class in combustion will meet weekly for eighteen weeks.

## Brief News Notes

**Electrical Voting Once More Proposed at Washington.**—A bill providing for the purchase and installation of an electro-mechanical voting system in the House of Representatives has been introduced by Representative Kelly of Pennsylvania. The cost specified is not to exceed $300 per member, or $130,500.

**Another Projected Merger in New York State.**—The Northern Light & Power Company has applied to the New York Public Service Commission for permission to acquire all the capital stock of the Malone Light & Power Company and to merge the two companies.

**East Tennessee County May Build a Million-Dollar Hydro-Electric Plant.**—A bill introduced in the Tennessee Legislature authorizes an expenditure of $1,000,000 by Sullivan County, Tenn., for the construction of a hydro-electric plant. The bill also authorizes the county to purchase water-power sites and build dams along the Holston River. It is thought the bill will pass.

**Federal Ownership of All Wire and Wireless Lines Proposed.**—A bill proposing government ownership and control through the Post Office Department of all electrical means for the transmission of intelligence for hire has been introduced in the House by Representative Sinclair, Republican, of North Dakota. Only farmers' telephone lines and amateur radio operators would be exempted.

**Radio Connection from Berlin to Budapest.**—Early in January radio-telegraphic connection by means of the Siemens "radional" system was begun between Berlin and Budapest. This new system allows the hourly dispatch of from 150 to 200 telegrams. The messages are sent in the ordinary alphabet and interception is almost impossible. Results thus far have been encouraging.

**Another Iowa Utility Purchase.**—The Creston Electric Light Company has purchased the Lorimor Light & Power Company. Necessary papers are being prepared for the consolidation of the Creston company with the Southern Iowa Utilities Company of Centerville. Creston has now been connected with Centerville through the continuation of a 33,000-volt line from Mount Ayr.

**General Electric Bonuses.**—The General Electric Company has just paid approximately $1,100,000 in bonds as supplementary compensation to the employees of its various plants who have been with the company for five years or more. This sum represents 5 per cent of the earnings of these employees for the six months' period ended Dec. 31. Of the total sum the Schenectady works received approximately $400,000.

**Licensing Bill in New Jersey Senate.**—An act enabling municipalities to license persons, firms or corporations engaged in the business of electrical contracting for the installation of interior wires or apparatus for electric light, heat or power purposes has been introduced into the Senate of New Jersey. It aims to "fix responsibility upon the electrical contractor for the safe installation of interior electrical work."

**Central Illinois Public Service Company Grows.**—The number of communities served directly by the Central Illinois Public Service Company has been increased to a total of 195 by the purchase of the properties owned by the Abbott Light & Power Company, operated from Petersburg, Ill. New communities included in the Abbott group that are served directly are Petersburg, Mason City, Tallula, Pleasant Plains and Ashland. Energy is wholesaled to eight other towns.

**Portland (Ore.) Installing Automatic Telephones.**—The Pacific Telephone & Telegraph Company of Portland, Ore., has just cut over about twelve thousand telephones, involving three exchanges, from the manual to the automatic system. The success with which this was done is evident by the fact that the actual work of the cut-over began at 11:30 p.m. on a Saturday night and soon after midnight subscribers were getting service over the automatic system.

**International Chamber of Commerce to Meet in Rome.**—The second general meeting of the International Chamber of Commerce will be held at Rome on March 18 to 24. Four group sessions and two general sessions will discuss matters of finance, an equal number of sessions will deal with industry and trade, and two group sessions and two general sessions will take up transportation problems. American delegates

sailed on Feb. 10 and will cruise the Mediterranean, visiting Palestine.

**Indianapolis Competition to Be Fought in Courts.**—The Indiana Public Service Commission has denied the petitions of the Merchants' Heat & Light Company and the Indianapolis Light & Heat Company, both of Indianapolis, for a rehearing of the case in which the commission granted the Terre Haute, Indianapolis & Eastern Traction Company permission to construct transmission lines in Indianapolis and thus become a competitor of the other two companies. Court action is now sought by the protesting utilities.

**A National Museum of Engineering.**—A joint committee on a National Museum of Engineering and Industry appointed by the four big engineering societies is formulating in co-operation with the National Museum of the Smithsonian Institution at Washington a plan for a great museum similar in character to the South Kensington Museum at London, the Conservatoire des Arts et Métiers at Paris and the Deutsches Museum at Munich, but more comprehensive in scope. This plan contemplates a central institution with local branches in different sections of the country. Edward D. Adams and Charles L. Clarke are the representatives of the A. I. E. E. on the committee.

**Steel Company to Buy Energy from Utility.**—The Commonwealth Steel Company, Granite City, Ill., has contracted for electrical power from the Madison County Light & Power Company, which is distributing energy from the Union Electric Light & Power Company of St. Louis. The total load will be 3,470 hp. and service will begin March 1. The decision to purchase central-station power was reached after a thorough analysis had shown it to be more economical than the production of power in the present plant. The Commonwealth Steel Company has one of the five large steel foundries which make the St. Louis industrial district the largest open-hearth-steel foundry center in the world.

**Iowa College to Train Metermen in March.**—Plans have been laid for the fifth annual course for electric metermen, to be held at the Iowa State College, at Ames, from March 12 to 16, 1923. The course on alternating-current meters is divided into four sections, depending upon the standing and previous experience of the metermen. One of these courses will be designed especially for meter superintendents and managers, and such topics as the effect of phase angle and ratio upon correct registration, the testing and care of standards and the metering of farm lines will be treated. A direct-current-meter course of instruction will consider the operation of the commutator and mercury-type meters and the standards used for direct-current testing. Classes comprising groups of six or eight men will be held from 8:30 a.m. until 4 p.m., and the evenings will be devoted to a discussion of the day's work. No tuition fee is to be charged.

**Interstate Merger Completed.**—The seven Indiana utilities whose consolidation with the Interstate Public Service Company has been finally approved by the Indiana Public Service Commission were valued by the commission as follows: Hydro-Electric Light & Power Company, Connersville, $1,132,212; Hawks Electric Company, Goshen, $1,124,903; Middlebury Electric Company, $18,953; Winona Electric Light & Water Company, $516,436; Electrical Transmission Company of Northern Indiana, $55,863; Southern Indiana Power Company, Williams, $1,382,672; Indianapolis & Louisville Railway Company, $1,840,000. The commission also allowed the Interstate to issue $3,100,000 securities to take the place of $3,139,950 in securities now out against the properties and in place of $1,808,156 of bills payable against one of the companies. The valuation figures submitted by the company were accepted by the commission.

**Worcester Co-operative Course Successful.**—About a year and a half ago the Worcester (Mass.) Polytechnic Institute put into effect a co-operative arrangement whereby students electing to do so at the end of the junior year might enter into fifteen months' engineering experience under commercial conditions, returning to the institute for their senior year's work at the end of their field service. While the plan is still too new for the publication of detailed results, Prof. H. B. Smith, director of the department of electrical engineering, states that the evidences of experience from the standpoints of the operating companies, the students and the institute are alike entirely satisfactory. Nine men are now at work in the senior class who have returned from their fifteen months' outside work and eleven men from last year's junior class are now in industry and are expected to return next September. It is probable that a larger number will go out from the present junior class into industrial work next June.

**Starting Appraisal.**—By order of the state utilities commission the Tennessee Electric Power Company is starting an appraisal of its entire system, which includes the physical properties of the former Tennessee Power Company, the Chattanooga Railway & Light Company and the Chattanooga & Tennessee River Power Company, which were merged into the Tennessee Electric Power Company last October. Among the physical properties of the Tennessee Electric Power Company are the 50,000-hp. hydro-electric plant at Hales Bar on the Tennessee River, two hydro plants of 45,000 hp. rating on the Ocoee River, a 20,000-hp. steam plant at Parksville and a 4,000-hp. steam plant at Chattanooga. The company also owns about 511 miles of high-tension lines connecting the above plants and extending over the state. Railway property is owned in Chattanooga. Tie connections exist with the Aluminum Company of America, with the Georgia Railway & Power Company and through the latter with the Alabama Power Company.

# Associations and Societies

**Ohio Electric Light Association.**—The new-business co-operations committee of this association will meet at Columbus on Wednesday of net week, Feb. 21.

**American Institute of Mining and Metallurgical Engineers.**—In connection with the four-day meeting of this society in New York City next week there will be a banquet at the Waldorf-Astoria on Wednesday evening, at which the Italian Ambassador, Gelasio Gaetani, will speak.

**Hartness Voices National Interests of the Engineer.** — Speaking before the Pittsfield (Mass.) Section of the American Institute of Electrical Engineers at the annual banquet Feb. 2, former Governor James S. Hartness of Vermont emphasized the importance of a closer study of economics and public affairs by engineers of all branches of the profession and pointed out the opportunities before technical men in the education of the public to a better comprehension of the problems of industry and economics. W. P. White was toastmaster and two hundred attended.

---

### Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

American Institute of Mining and Metallurgical Engineers—New York, Feb. 19-21.

Wisconsin Engineering Society—Feb. 22-24. L. S. Smith, College of Engineering, Madison.

American Physical Society—New York, Feb. 24; Washington, April 21. D. C. Miller, Case School of Applied Science, Cleveland.

Pennsylvania State Association of Electrical Contractors and Dealers—Lancaster, Feb. 28. M. G. Sellers, 1518 Sansom St., Philadelphia.

Oklahoma Utilities Association—Oklahoma City, March 12-14. O. D. Hall, 1106 First National Bank Bldg., Oklahoma City

Southwestern Division, N. E. L. A.—Oklahoma City, March 14-16. S. J. Ballinger, San Antonio Public Service Co., San Antonio, Tex.

Illinois State Electric Association—Chicago, March 14-15. R. V. Prather, 305 Mine Workers' Bldg., Springfield, Ill.

Wisconsin Utilities Association—Milwaukee, March 22-23. John N. Cadby, 445 Washington Bldg., Madison.

Tri-State Water and Light Association—Birmingham, April 17-20. W. F. Steiglitz, Columbia, S. C.

American Institute of Electrical Engineers — Spring convention, Pittsburgh, April 24-26; annual convention, Swampscott, Mass., June 25-29; Pacific Coast convention, Del Monte, Cal., Sept. 25-28.

American Electrochemical Society — New York, May 3-5. Colin G. Fink, Columbia University, New York.

Southwestern Public Service Association—Fort Worth, Tex., May 15-17. E. N. Willis, 403 Slaughter Bldg., Dallas, Tex.

Electrical Supply Jobbers' Association—executivo committee and general meeting, Hot Springs, Va., May 21-25. Franklin Overbagh, 411 S. Clinton St., Chicago.

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

Electric Power Club — Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

Pacific Coast Electrical Association — San Francisco, June 19-22. S. H. Taylor, 527 Rialto Bldg., San Francisco.

## Recent Court Decisions

**Damages from Overflow Due to Increasing Height of Dam.**—Grants of privileges to maintain dams over watercourses are to be read and construed in the light of the times and circumstances under which they are granted. So stating, the Kansas City Court of Appeals, in Cambest vs. McComas Hydro-Electric Company, sustained a verdict for the plaintiff, an abutting landowner, for damages due to the overflowing of his land through the raising of the height of a dam in the Platte River from 8 ft. to 15½ ft. The action of the company in raising the dam under a provision of an act of 1845 was found unwarranted in equity, and an assertion of the defendant that the abatement of the dam would cause loss to it out of proportion to the damage sustained by the landowner through its maintenance was declared not to be a valid defense. (245 S.W. 598).*

**Power to Limit Security Issues.**—The power of the Michigan Public Utilities Commission to fix the amount of the issue of stock and bonds and to fix it at the value of the property has been upheld by the Michigan Supreme Court in Hillsdale Light & Fuel Company vs. Commission. It was contended that if the commission finds that the property is reasonably required for the purposes of the utility and the funds are to be used for a lawful purpose, it is beyond the power of the commission to limit the amount of stock or bonds to be issued and that this question must be left to the judgment of the governing board of directors of the corporation. The court held that the purpose of the act involved was to prevent the overcapitalization of public utilities and that the amount of capital stock and bonds should correlate with the amount and value of the company's property. (189 N. W. 893.)

**Burden on Dependent to Establish Basis for Measurement of Compensation.**—To justify an award to a dependent widow or children, under the terms of the workmen's compensation law of Minnesota, of any amount in excess of the minimum there allowed, the claimant has the burden to supply by competent evidence the basis for the measurement thereof as limited by that statute. So holding, the Supreme Court of Minnesota, in Kreidler vs. Mahnomen Electric Light & Power Service Company, decreed that the plaintiff, whose husband, an electrician earning 80 cents an hour, was not regularly employed by the defendant but was fatally injured while temporarily working for the company, was entitled only to the minimum compensation fixed by the statute ($6.50 a week), the evidence failing to establish that the man ever continued even a week in the service of the defendant at one time. The contention that he worked as a contractor and not as an employee was, however, overruled. (191 N. W. 277.)

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

**Power Company Suable in County in Which It Overflowed Land by Dam in Another County.**—In Price vs. Ketchum and Georgia-Alabama Power Company suit was brought for damages to land caused by the overflow of a dam belonging to the power company, to which Ketchum, who, it was alleged, had failed to carry out an agreement with Price regarding the purchase of timber on the land in question, had granted permission to back water and overflow the tract. This flooding had, plaintiff contended, destroyed the timber, to which he still claimed title. The Court of Appeals of Georgia has reversed a judgment dismissing the action, this action having been based in part on the contention that the case could not be tried in the county where the damage was done inasmuch as the dam was in another county. The finding also holds that a provision of the deed regarding overflow of the land by a third party did not liquidate damages so as to prevent action. (115 S. E. 32.)

**Duty of Companies to Maintain Proper Insulation on Transmission Wires.**—Premising that it is the duty of a corporation that maintains and controls wires charged with electricity in a place where it is likely that persons will come in contact therewith to use reasonable care to maintain proper insulation, and that the test of liability to a particular person is whether injury to him ought reasonably to have been anticipated, the Court of Errors and Appeals of New Jersey affirmed a verdict for the plaintiff in McGinnis vs. Delaware, Lackawanna & Western Railroad Company. In this case the defendant corporation maintained a wire across a public highway 18 ft. or 20 ft. above the surface of the street. A workman driving piling in the street came in contact with the wire and was killed. Whether or not the defendant's wire was maintained by legislative authority and whether or not the work upon which decedent was engaged was done under a city permit did not appear. The court held that the jury might infer negligence from evidence tending to show want of reasonable care in the insulation of the wire; that the mere fact that defendant's wire was strung 18 ft. or 20 ft. above the surface of the street did not relieve it from liability, since from the appearance of the pile driver and the place, progress and duration of the work it was open to the jury to find that the defendant should have foreseen the danger and anticipated injury to the decedent; that the fact that the work in the street upon which decedent was engaged was being done without a permit from the city would not defeat recovery, since the absence of a permit did not contribute to the injury and there was nothing to show that the work unreasonably interfered with the rights of the defendant or others in the street, and that the fact that decedent worked in close proximity to the wire could not be said as a matter of law to be negligence barring recovery, since the evidence tended to show that the wire was apparently safe and that decedent was without knowledge of its dangerous character. (119 At. 163.)

## Commission Rulings

**That There Is Only One Customer Does Not Deprive a Public Service of Its Nature.**—In a complaint asking that the tariff schedule of the Carlisle Light, Heat & Power Company covering rates for furnishing live steam for industrial heating be stricken from the files of the Public Service Commission of Pennsylvania, on the ground that the complainant was in fact the only user of live steam, and that respondent in the particular service was not functioning as a public utility, the commission dissented from the latter assertion and dismissed the complaint.

**Idaho Commission on Expense of "Attaching Business."**—In arriving at a valuation of the property of the Pocatello Gas & Power Company for rate-fixing purposes, the Idaho Public Utilities Commission had this to say on the expense of getting new business as an element in "going value": "Under business development there is rightfully included the cost of attaching business. The record shows that there was expended the sum of $45,916.88 for the purpose of attaching business. The methods employed by the company in attaching business were somewhat peculiar, yet it was probably as good a method as any which could have been devised under all the circumstances then existing. It is not the province of the commission to criticise any reasonable method employed by the utility in attempting to attain the end sought. The evidence discloses that at such time something was necessary, and the company, acting upon its best judgment, has partially accomplished the purpose sought. The business of the company has not yet reached the stage where the value of the business developed justifies the allowance of the above amount. The evidence shows that this company has not as yet reached that point where it has been able to pay operating expenses, taxes and a reasonable return. However, the company is entitled to have included in its rate base a reasonable amount for the cost of business development. Under all the conditions presented in the case the sum of $10,000 is a reasonable allowance for business development, when considered in conjunction with the value of the business as a going concern, and the sum of $10,000 will be allowed with the going-concern value included therein."

# Men of the Industry

Changes in Personnel
Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry

### B. I. Budd President Northern Illinois Company

Britton I. Budd, elected president of the Public Service Company of Northern Illinois, as was announced in the Feb. 10 issue of the ELECTRICAL WORLD, has been associated with the transportation business ever since he left school, at which time he took a situation in the surveying department of a steam railroad in Ohio. In 1893, during the World's Fair at Chicago, Mr. Budd was associated with the Intramural Railway. With the incorporation of the Metropolitan Elevated he saw Chicago's future transportation plans take real form, and when actual operation of that line was commenced in May, 1895, he obtained a position as clerk in the storehouse. With the Metropolitan his rise was rapid, for he soon became storekeeper, then purchasing agent and finally general manager. When Mr. Hetzler, president of the Metropolitan, left in 1910 Mr. Budd was elected president.

B. I. BUDD

In 1911 a consolidation of all the elevated lines in Chicago was brought about, and Mr. Budd was chosen president of the combined system. Besides being president of the Chicago Elevated Lines, he became president of the Chicago, North Shore & Milwaukee Railroad at the time of that line's reorganization in 1916. Mr. Budd will continue as president of both these organizations.

**Joseph S. Lessig** has been appointed local manager of the Winona Electric Light & Power Company at Warsaw, Ind., which was recently consolidated with the Interstate Public Service Company.

**Henry H. Russell**, for the past three years Southern district manager for the Edison Electrical Appliance Company, is now associated with Mitchell Vance, Inc., New York.

**Theodore B. Parker**, formerly assistant hydraulic engineer for the Utah Power & Light Company and later for the Electric Bond & Share Company, New York, has entered the hydraulic division of Stone & Webster, Boston.

**Robert E. Barrett**, well-known in New England hydro-electric circles, has been elected president of the Holyoke (Mass.) Water Power Company. Mr. Barrett was formerly on the engineering staff of the Turners Falls (Mass.) Power & Electric Company and for several years has been the active manager of the Holyoke company with the title of treasurer.

### C. L. Law Receives New Appointment

Clarence L. Law, for many years manager of the bureau of illuminating engineering of the New York Edison Company, has recently been appointed to the post of assistant to the general commercial manager, Arthur Williams. Mr. Law has been associated with the company since 1906, when he entered its service as special inspector. A year later he was made special agent and in January, 1910, he was made manager of the bureau of illuminating engineering. Notwithstanding the demands of his office, Mr. Law has found time for great activity in the affairs of the various organizations of the electrical industry. He is now serving as chairman of the metropolitan New York company section of the National Electric Light Association. He served two years as vice-president of the Illuminating Engineering Society, for five years was its general secretary and is now serving as one of its directors.

### A. E. Reynolds Goes to Springfield, Mo.

Albert E. Reynolds, who recently resigned as general manager of the United Traction Company, Albany, N. Y., and Hudson Valley Railway Company, Glens Falls, N. Y., subsequently announcing his association with E. N. Sanderson of Sanderson & Porter, president of the Federal Light & Traction Company, New York City, has been elected vice-president and general manager of the Springfield Gas & Electric Company and Springfield Traction Company of Springfield, Mo. This is one of the subsidiary companies of the Federal Light & Traction Company. He entered upon his new duties at the beginning of the month. He succeeds E. C. Deal, who resigned from the Springfield properties to become associated with the Electric Bond & Share Company of New York. Mr. Reynolds has had many years of experience in the utility field which amply qualify him for his new work.

### J. M. Barry Manages Alabama Company's Southern Division

J. M. Barry, who since the spring of 1921 has been assistant chief engineer of the Alabama Power Company, has been promoted to the position of manager of the southern division of the company, with headquarters at Montgomery. With the acquisition of the Montgomery electric service system, the possibilities of future hydro-electric development on the Tallapoosa River and the opportunities for expansion in the southern part of the state, this division has probably the greatest possibilities of growth existing on the entire system. As manager of the division Mr. Barry will have charge of all physical properties, public relations, commercial activities and operating and maintenance in that section.

J. M. BARRY

Immediately after graduation from college in 1910 Mr. Barry joined the Pacific Gas & Electric Company's underground department in Sacramento, Cal., where he stayed for two years, then becoming electrical engineer of the Northwestern Electric Company, Portland, Ore. From 1914 to 1917 he was chief of the San Francisco department of electricity, and during the next two years he was distribution engineer of the Great Western Power Company. In 1919 he became connected with the Alabama Power Company, where he had charge of the eastern division until 1921.

**Jerome Blaisdell** has resigned from the Depew & Lancaster Light, Power & Conduit Company at Lancaster, N. Y., and is now associated with the Central Michigan Light & Power Company at Alma, Mich.

### W. H. Taylor Elected Vice-President of Georgia Company

W. H. Taylor, formerly executive assistant of the Georgia Railway & Power Company, has been elected a vice-president of that company. Mr. Taylor is a widely known public utility executive, having been for seven years president of the Omaha Gas Company. Prior to his connection with the Omaha company he was with the United Gas Improvement Company as engineer in

W. H. Taylor

charge of the gas and electrical properties on the main line out of Philadelphia. He had previously served with the Fulton County Gas & Electric Company, Gloversville, N. Y., for a period of three years, where he was also engaged in engineering work. Previous to his association with the Georgia Railway & Power Company he was stationed in Philadelphia as an executive on matters of appraisal. Mr. Taylor is a graduate of the Stevens Institute of Technology, Hoboken, N. J.

**C. B. Merrick**, formerly in the inspection department of the San Joaquin Light & Power Corporation, has been placed in charge of the range department of the Valley Electrical Supply Company of Fresno.

**Joseph George Ramsden** is now a director of the Ontario Power Company of Niagara Falls, replacing Fred R. Miller, deceased, and D. Carmichael is vice-president of the company, replacing I. B. Lucas, resigned.

**Stanley Walton**, for thirteen years a member of the commercial department of the Pacific Gas & Electric Company and until recently sales manager of the gas and electric departments, has resigned to become sales manager of the Bonestell Paper Company.

**Thomas W. Wootton**, formerly connected with the Hydro-Electric Department, government of Tasmania, and later with the General Electric Company, has resigned to accept a position with the engineering department of the Adirondack Power & Light Corporation, Schenectady, N. Y.

**E. T. Fishwick**, general sales manager, has been appointed vice-president of the Worthington Pump & Machinery Corporation, New York, succeeding Frank H. Jones, who resigned.

**George W. Bernhard**, formerly manager of the northwestern district of the Great Western Power Company and special agent at Sacramento, has been named district manager at Oakland.

**Ernest Johnson**, formerly connected with the Holmes Electric Company, Fayetteville, N. C., is now associated with the Westinghouse Electric & Manufacturing Company.

**Jesse Huff**, formerly of the United States Patent Office examining corps, has resigned to become associated with the patent department of the General Electric Company at Schenectady, N. Y.

**A. J. Chapman**, formerly sales manager of the Gainaday Electric Company, Boston, has been appointed assistant sales manager of Beaudette & Graham, distributors of electrical household appliances in the same city.

**Ralph B. Coleman**, formerly in charge of the Chicago office of the Moloney Electric Company and also with the Electric Machinery Company, Minneapolis, for five years, has joined the forces of the Shakstad Electric Company, Sioux Falls, S. D.

**R. L. Bennett**, formerly sales manager of the Crystal Washing Machine Company, Detroit, and sales and advertising manager of the Air-Way Electric Appliance Corporation, Toledo, has been appointed general sales manager of the Berthold Electrical Manufacturing Company, Chicago.

**John Gribbel** of Philadelphia has been elected a member of the board of directors of the Cities Service Company. Mr. Gribbel is owner of John J. Griffin & Company, president of the Royal Electrotype Company of Philadelphia and the Athens (Ga.) Gas & Fuel Company, and vice-president of the American Railways Company of Philadelphia and the American Meter Company of Delaware.

**J. Fisher**, electrical engineer and contractor, was elected president of the Denver Association of Electrical Contractors and Dealers at the annual election held by that organization on Jan. 23. E. A. Scott was chosen as vice-president and H. Alex. Hibbard, a Denver manufacturer's representative, as secretary and treasurer. The three officers are members of the advisory board of the Electrical Co-operative League in that city.

**F. P. Cummings**, efficiency engineer of the Alabama Power Company, has been transferred to the position of commercial manager, where he succeeds F. D. Mahoney, who has joined the West Penn Power Company, with headquarters in Pittsburgh, Pa. Previous to Jan. 1, 1920, Mr. Cummings was operating manager of the Alabama Power Company for some time. Several years ago he was with H. L. Doherty & Company and, among other offices, held the position of commercial manager in Joplin, Mo.

### J. L. Longino Vice-President of Arkansas Company

J. L. Longino, who was formerly operating superintendent of the Arkansas Light & Power Company and has served as its secretary and treasurer since organization, has been made vice-president and general manager of the company. Mr. Longino was made manager about two years ago of the Pine Bluff Company, an associated public utility company, which operates the

J. L. Longino

street-railway, electrical and water services in Pine Bluff. He will continue to manage the Pine Bluff Company, but will be relieved of some details by L. B. West, the auditor. The secretaryship of the Arkansas Light & Power Company has been taken over by L. Garrett.

**E. F. Stoughton** has been transferred from the treasurer's office of the Stone & Webster organization to the Cape Breton (N. S.) Electric Company.

**C. E. Brigham**, who was associated with the National Radio Institute at Washington, D. C., for two years, and more recently with the Radio Testing Laboratories of the United States Navy, has been appointed research and designing engineer for C. Brandes, Inc., of New York City.

## Obituary

**Dr. W. French Smith**, president of the Mexican Telephone & Telegraph Company, died at his home in Somerville, Mass., Feb. 1, at the age of sixty-eight. Dr. Smith was well known in the metallurgical field aside from his interest in the development of foreign telephone service.

**John S. Connell**, sales representative of the Frank H. Stewart Electric Company, Philadelphia, died at Elmira, N.Y., on Wednesday, Jan. 31, while making a business trip. Mr. Connell had been associated with the company since 1907 and for a period of several years had served on the board of directors of the company.

## Two Letters on Distribution

### A Jobber Writes that It Is Public Demand for Extravagant Service that Makes Our Distribution Too Costly— A Further Analysis

A RECENT editorial in the ELECTRICAL WORLD on distribution costs concluded with this statement:

> **"But the public demands relief. Will electrical men and other industries, we wonder, find ways to cut down their costs by co-operation among themselves, or will they wait until Congress is driven by public clamor to tackle the whole job with many ill-considered laws?"**

The following letter from a jobber in the West argues that the responsibility for reducing this cost lies more with the public than with industry—a not uncommon point of view.

Of the facts as cited in this jobber's letter, there can be no question. The point is: Can the matter safely be left to the public to correct, or must industry act in its own behalf? Also, how much does industry contribute in its turn to this condition? This thought is discussed in a letter of reply, further analyzing the issue and showing that the editorial and the jobber's thinking are really not at variance. But the man of the industry naturally thinks as a jobber, a manufacturer, and is apt to see his opportunity to influence in distribution costs restricted to the field of his present activities. Progress will only be made, however, when these men take hold to get the job done for the industry as well as for the public, no matter where the work must be performed.

*To the Commercial Editor of the* ELECTRICAL WORLD:

DEAR SIR: For some time I have been holding on my desk a reprint of an editorial published in the ELECTRICAL WORLD on Saturday, Nov. 25, 1922, entitled "Distribution—Who Will Cheapen It?" This editorial was, of course, written with the idea of constructive help, but I am wondering whether it does not hurt the electrical industry more than it helps. The last paragraph of your article asks a very pertinent question as to what will be done to cut down the cost to the consumer, but limits this solution more or less to the producer.

It is unfortunate for the electrical industry that electrical men are trying to establish ideas of merchandising that are so totally different from the methods used in merchandising other classes of merchandise used by the public. My particular point is that you bring out the fact that a labor-saving device costing the manufacturer $50 sells for $125. How about the pair of shoes that you happen to be wearing while you are reading this letter? It is my opinion that you will find the same discrepancy between the cost of manufacture and what you paid for the shoes, and the demand that you personally made for service has caused this wide discrepancy.

Recently I had the pleasure of visiting one of the largest certified milk-producing plants in this country, and the reason I am speaking of this is because it represents a commodity that is consumed every day and on which the distribution cost should be lower than it would be on any appliance such as the electrical industry has to offer. However, I found this concern was making a pretty fair profit on its investment, was delivering the milk via train and truck to a town 75 miles away, delivering it to the man who takes it to the door of the home, for 13 cents a quart. The householder pays 25 cents a quart for this milk. Of course, many of these householders would like to have that milk a little cheaper, but the demand is such that there is no trouble in getting 25 cents. The public has made that price by demanding that the milk be put up in fine glass bottles, thoroughly sterilized, with patent caps, delivered to the door of the home in nice, clean, well-kept wagons or automobiles, by men dressed in white uniforms, always spick and span; that the bills be collected at the end of the month, and that it shall have the many other things that go under the head of service.

I have no doubt that if the public in general were willing to go back to the time of my boyhood days, when the dairyman came to the back door with a great big can, measured out the milk in the cover of the can, and poured it into a bucket that my mother stood holding in the doorway, the milk could still be purchased at the same price that my mother paid for it, and that is about 5 cents a quart. Our family seemed to have thrived on that dreadful milk that was neither pasteurized sterilized or any other "ized," but since we are now all so afraid of the many bugs, germs and other things that might be in the milk, in the wagon or in the clothes of the driver, we must pay the price.

It may seem to you that it is a long step from milk to washing machines, but if you will stop a few of the many things demanded by the public in the way of service, there should be less difference between the bare cost of the merchandise and the selling price. The washing machine should or will last ten or fifteen years—the family cannot drink it up every day—which is another factor that must be taken into account in the final analysis of the retail price.

The only solution that I can think of is a general propaganda throughout the United States to train the public to realize that our ways of living today are all wrong—that we must go back thirty-five or forty years in our ideas and be satisfied with the conditions, conveniences and ideas of that time. If the public is going to keep on demanding what is considered "modern service," then that public must pay that bill—in other words, if one will drive the old, broken-down gray mare up to a decrepit-looking country store, knock the proprietor down and take away from him a washing machine without all the beautiful enamel and one that does not look like a baby grand piano, pay cash for it, and then not have to have a man sent out every thirty or sixty days to see whether it is oiled or not, I think your problem would be solved and the question in your editorial fully answered.

I do feel that it is a pity that the press and everybody connected with the electrical industry keep harping on the dreadful difference between the cost of production and the cost to the ultimate user, without a proper analysis of the other classes of merchandise. Very truly yours,

———————,
Vice-president.

MY DEAR MR. JOBBER: I agree with you entirely that the present "spread" on electrical devices is no greater than on shoes or clothes or milk or a dozen other lines that we can tell off on our fingers. In fact, it is not so great. I'll go you one further and say that the profit which electrical dealers and jobbers are making on many commodities is too small, far smaller than is earned for like service in other industries. But it is not profit that we are talking about, it is cost, and the general agitation through the country today in opposition to the present costs of distribution applies to food products, clothing and general manufactures no less than to electrical commodities.

The retail price of $125 on the indefinite appliance costing $50 to manufacture, which was cited as an example, is too great. But it is too great not because the agencies of distribution are making too much profit, but because the system of distribution by which they are operating is too costly. The purpose of the editorial was to say just this, that distribution is costing too much, that people are beginning to realize it and are demanding redress, and that it is better for the men of the industries affected to recognize this and do something to correct the situation than to let it ride until Congress undertakes to reform it with laws.

You are undoubtedly right in saying that the American public is demanding today an extravagant scale of service. The reason that the quart of milk sold at wholesale at 13 cents costs 25 cents delivered is because the public is buying not just a quart of

milk but also sterilization, patent caps and delivery in glass bottles by mean in clean, white uniforms who arrive in well-kept automobiles. They are purchasing not just milk but milk plus de luxe delivery, and this is true in our modern habits of buying most of our family supplies and in our personal purchases.

This is the cause of a good part of the present cost of distribution, but not all. Another part of it is our present system, wherein the dealer demands like extravagance in the service from the wholesaler and the wholesaler demands like extravagance in service from the manufacturer. This extravagance is expressed in small orders, excess varieties, wasteful packing and a dozen different other sources of unnecessary expense which come readily to mind.

Undoubtedly the public has forced a sizable part of this exorbitant distribution cost, but the electrical industry cannot sit back and say, "Because of this we will do nothing." For, in the last analysis, the public has the power and can do something about it itself through legislation, and the thing that they do may be the wrong thing. Therefore the electrical industry and other industries involved in the problem will be compelled to look the situation squarely in the face and take upon themselves the responsibility for influencing toward cheaper distribution in both these directions. That is, they must improve the economics of their own operations in so far as is humanly possible, and they must show the public clearly how great an element in the cost of commodities the modern standards of extravagant service which this generation is demanding have become.

We cannot passively sit back and wait for the public to find this out. Somebody has got to make this clear to the people and help them to see just how much of the price of goods is service and how much is commodity. And it would be far better for electrical men to undertake this job for their own protection than merely to deplore the condition and do nothing. I feel, therefore, that the industry itself has got to find the answer to the problem and to satisfy the public. It can do this in two ways—by introducing economies to eliminate existing costs that are excessive and by explaining more clearly to the people just what it is that makes up the cost of a commodity. Frankly, I do not believe the fact that similar conditions exist in other industries justifies any manufacturer or any jobber ignoring wasteful practice which he may be contributing to the high cost of distribution in his own business. I am sure that you will agree with me. Very truly yours,

——— ———,

Commercial Editor.

# High Cost of Inspection Inconsistency

## Some Pertinent Facts on the Excessive Variety of Switches Forced Upon the Industry by Lack of Uniformity in the Methods of the Inspectors

By T. J. Kauffman
Treasurer and General Manager
Square D Company, Detroit

If THE leaders of the electrical industry are earnest in their interest in the betterment of conditions now obtaining in the manufacture and distribution of electrical products, there is a worthy work for them to do in the reduction of the inconsistencies in inspection as it is practiced throughout the country. At the present time the requirements of the inspection authorities in different states and different cities vary so greatly that it places a costly burden on the manufacturer and the jobber of many devices that are used in the premises of the consumer and adds materially to the expense of an electrical installation.

No one who is not engaged in the manufacture or distribution of such a product can appreciate the effect of these conditions and the extent of the burden which it unnecessarily inflicts. The object is always the same, to reduce some hazard to life or property by giving extra protection against shock or fire. But the methods differ. The men who devise the methods have varying opinions and do not interpret either the requirements of the code or the local conditions alike. As a result there has grown up a great diversity of demands for special equipment, and the manufacturer who wishes to sell in these markets must prepare all their duplicating varieties and the jobber must stock them. It all wastes money.

Take the switch, for instance. There is a big variance of opinion among electrical inspectors here as to the application of the national electrical code. Atlantic City, N. J., requires that switches must have slate bases and will not permit the use of porcelain-base switches even for ordinary residence service. Porcelain-base switches prove satisfactory in all other localities as far as I am aware, even those localities adjoining Atlantic City; but they may not be used in Atlantic City. And so it goes.

There are throughout the large cities of the United States at least twelve different requirements, I am certain, for ordinary 30-amp. entrance switches of the inclosed safety type. If the manufacturer does not manufacture switches to meet all of these requirements, he is barred out of certain cities, and to the best of my knowledge no manufacturer does make a line of switches complete enough to meet all twelve requirements. For example, in the city of Buffalo a device is required which is not manufactured for any other city in the country that I know of. For a manufacturer to attempt volume production would be impossible. No one could take on the manufacture of this Buffalo device, because a plant organized for volume production could not handle the device to advantage.

Again, in some cities it is not permissible on three-wire grounded-neutral systems to use a switch with a blade or a fuse or both in the neutral. In other cities, however, three-pole switches with three blades and two fuses are required even though they are not required by the National Electrical Code.

In one city in Michigan the cover of an inclosed-switch box must be so hinged that it will not break a sign receptacle when the sign receptacle is placed at the bottom of the switch, used as a fuse block, even though the use of a sign receptacle in this manner is a direct violation of the code. In other cities they will not permit the use of an inclosed externally operated switch unless it has an interior locking-off device. Other cities require that the locking-off device must be on the exterior of the switch so that it is plainly evident to the user when the switch is locked off. Some cities specify special solder lugs on inclosed externally operated switches as small as 30 amp. in size.

### Disregard Code and Labor

Some of these requirements are due to the ideas of those in charge of meter installations for the utilities. In other cases they are due to the ideas of the electrical inspectors. While the inspectors are somewhat more uniform in their requirements, we have run into several cases where inspectors working for the Underwriters' Laboratories have refused to approve switches which are approved by the Underwriters' Laboratories for the services on which they were placed and although the switches bore the Underwriters' label. Another inspector refuses to permit the use of a solid neutral even though it is approved by the code.

It is not to be expected, of course, that industrial engineers can agree on a certain general type of safety switch for all purposes, but it does appear that a great deal of work will have to be done toward the adoption of some general type of service switch that will meet the approval of those in charge of meter installations

of large utilities and that will also meet the approval of the various inspectors who have jurisdiction over this kind of work.

Because of these conditions this company manufactures ten different kinds of two-pole, 30-amp., 125-volt service switches, whereas if the authorities would agree on the one best type and then all localities would agree to permit the use of that type it would only be necessary for us to manufacture the one type. This would save us a great deal of money, and as this saving would be passed along, it would eventually reach the consumer and would be of benefit to every one who has anything to do with the industry.

### Increases Cost

And so it is in many other lines where inspection requirements differ. If one type could be made that would be acceptable to all states and municipalities, manufacturers could put that number into quantity production and turn them out at a low price. As things stand, however, the volume is cut up into five, ten or twenty styles, all duplicating except in some superficial detail, and the overhead cost goes up both for the maker and the distributor.

In Massachusetts the Boston jobber must carry in stock a type of switch which is required in Boston. He must also carry in stock another switch which is almost the same but does not meet the Boston requirements, although it is commonly used in other localities surrounding Boston. He must, in addition, carry in stock a cheap inclosed switch to meet the requirements in localities where inclosed switches are specified with no particular type mentioned. Then he must have the old cheap switch to meet the demand in the localities where even inclosed switches have not as yet been required. It is not hard to see how this affects the Boston jobber.

Here is a matter of fundamental importance. The purpose of all these inspectors and all this legislation is to make the use of electric service safe, and the electrical manufacturer and jobber is ready to co-operate in every way. But when a safer way is found, by the very nature of the thing, it must be as safe in Oregon as in Pennsylvania. Therefore the industry should be permitted to make the safe switch without burdening its cost with a whole assortment of excess varieties. And the jobber should be permitted to stock and sell that switch without investing money and filling shelves with duplicating styles that slow down his turnover and increase the cost of distribution.

It is time that our associations, representing all branches of the industry—for all are concerned and should be interested—take up the task of reconciling these inspection inconsistencies. It will be a work of education, but the need is so urgent and the purpose so obvious and commendable that it should be possible to make rapid progress.

# Business Conditions

A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand

## Conduit Boxes Are Plentiful

Notwithstanding the uneven stocks of rigid conduit reported from many sections, the supply of conduit boxes appears to be comfortably meeting current demands, and the recent price advance in pipe and other steel products has not at this writing been applied to this line of supplies. The increasing use of metallic conduit, both rigid and flexible, tends to develop a wider market for boxes; but so far it has been no very difficult matter to maintain adequate stocks in most quarters, though there is no ground for becoming careless in ordering when inventories shrink materially. There is nothing of a spectacular character about today's box demand as reported to this journal Monday. Contractor-dealers are the principal buyers, and jobbers are worrying over other topics than this.

## Instrument Demand Improving

Demand for electrical instruments is improving, according to several manufacturers in the field. A slight betterment in the automotive industry is reported, the orders from the farm-lighting plant makers are steady, the central stations are buying in fair amounts, and inquiries from boiler plants are growing. Stocks of general lines are normal, and makers state that special orders are being made up in satisfactory time. No trouble in deliveries of materials is reported. The present volume of business is expected to continue at a normal rate and, according to the leading manufacturers, can do nothing but improve when the heavier buying starts in the late summer or early fall months. Manufacturers are particularly optimistic over this year's business in view of the heavy construction programs and general business conditions.

## Chicago Collections Better

Some indications that collections among Chicago electrical jobbers are improving may be taken from their reports that a greater number of customers are taking advantage of cash discount terms. The volume of purchasers benefiting by cash payments within ten days is constantly growing. On an average the regular collections are running around forty-five to fifty days, which is much better than last year's.

Commenting on this situation, J. P. Wilson, credit manager Central Electric Company, declared that for the last three months of 1922 his collections had been the best of the entire year. The only item necessitating careful scrutiny as to credit rating, he maintained, was the radio business, which was not allowed to run over thirty days. Other jobbers report that the year ironed out many of the credit difficulties, so that conditions in the Middle West were much better than in 1921.

## Expect Firm Prices for Farm-Lighting Sets

Improved agricultural conditions throughout the country are expected to bring about a better market for farm-lighting plants during the summer months. Several large companies are planning extensive sales campaigns to educate the farmer in the money-saving features of the lighting sets in order to make 1923 a record selling year. It is also planned by companies to send many more demonstration sets mounted on light automobile trucks to the rural districts. The outlook in the southern districts is encouraging. Several well-known jobbers state that they are in receipt of many inquiries from farmers as a result of advertising in the newspapers, and that as soon as the roads are in better condition they will be allowed to close quite a few orders. This advertising offers from twelve to twenty installment payments. Manufacturers generally are of the opinion that prices will remain firm during the next three months.

## Tape Demand Reflects Steadiness in Wiring Field

A steady demand for tape, following a lull of short duration, appears to have set in. Local stocks have been meeting current requirements readily, but the market continues to be characterized by sharp distinctions in quality and price and accompanying spotty buying from particular localities. There is some discussion in manufacturing circles relative to price levels, some of the

newer comers into this field having quoted on bases which some of the older houses have questioned as insufficient to cover all charges properly belonging to this commodity in its journey from the raw-material stage to the distributor's shelf. Be this as it may, the importance of careful buying of tape for the particular service expected seems to be gradually getting more recognition, and the factor of quality is bound to grow in significance. Black tape is in much greater demand than white, and the striking success of interior-wiring campaigns the country over is sure to help the year's sales record in this line.

## Electrical Opportunities in China

### American Capital Needed to Aid in the Development of Industry and Transportation

"Despite unfavorable political conditions which show no indication of early improvement, commercially speaking, China is solvent," said Julean Arnold, commercial attaché to the American Legation at Peking, in a recent interview with a representative of the ELECTRICAL WORLD. "Once again, for the twentieth time in the past two decades, China's foreign trade shows an increase over the preceding year. Neither the domestic political condition nor the widespread depression of business in many parts of the world in 1922 breaks the continuity of the gradual upward development in foreign commerce. China's per capita debt is under $3, and the entire debt is no more than the funded debt of New York City. The number of Chinese banks in various trade centers is increasing, and important investments are being made in the country by Belgian, British and French interests.

Mr. Arnold pointed out that American trade with China has now reached about $200,000,000 per year, or a fourfold increase since 1900. The total American resident population is about 12,000. The popularity of central-station service is increasing by leaps and bounds, and in the cities where this service is in use the demand for electric lighting overloads the plants every four or five months. New facilities are constantly required. Outline lighting on the Nanking Road, at Shanghai, compares favorably with any American installation. Extensive additions to the station of the Canton electric lighting plant are now under contract.

The competition of cheap electrical supplies made in Japan and in Germany is a present handicap against American goods. Mr. Arnold commended the policy of the General Electric interests in China in refusing to produce cheap supplies in their China factory to meet the competition. It is believed that the quality of American electrical supplies will ultimately win their wide acceptance in China owing to the high regard the Chinaman has for established trademarks and proved goods.

DELINQUENT ELECTRICAL ACCOUNTS FOR JANUARY

| Branch and Month | Number of Delinquent Accounts Reported | Total Amount | Average Amount |
|---|---|---|---|
| Central Division: | | | |
| December, 1921 | 1,157 | $124,376.98 | $107.49 |
| December, 1922 | 1,104 | 126,342.89 | 125.84 |
| January, 1922 | 820 | 93,956.53 | 118.24 |
| January, 1923 | 809 | 88,811.52 | 109.78 |
| New York: | | | |
| December, 1921 | 434 | 58,840.00 | 136.00 |
| December, 1922 | 485 | 93,428.00 | 193.00 |
| January, 1922 | 325 | 48,429.00 | 150.00 |
| January, 1923 | 392 | 54,452.00 | 139.00 |
| Philadelphia: | | | |
| December, 1921 | 186 | 28,992.97 | 155.87 |
| December, 1922 | 183 | 19,307.58 | 105.51 |
| January, 1922 | 216 | 32,449.17 | 150.23 |
| January, 1923 | 212 | 30,786.13 | 145.22 |
| New England: | | | |
| December, 1921 | 44 | 8,484.25 | 192.82 |
| December, 1922 | 34 | 3,809.68 | 112.05 |
| January, 1922 | 3 | 454.48 | 151.49 |
| January, 1923 | 66 | 7,805.66 | 118.27 |
| Pacific Coast: | | | |
| December, 1921 | 23 | 2,677.74 | 107.72 |
| December, 1922 | 14 | 2,225.43 | 158.90 |
| January, 1922 | 16 | 2,002.00 | 125.12 |
| January, 1923 | 12 | 1,087.20 | 90.60 |

## Number of Delinquent Accounts Was Lower in January

Delinquent accounts as reported by the Electrical Credit Association show that the Chicago accounts were lowered by 295 over the year end. The average value of the January, 1923, accounts was $109.78 as against $125.84 for December, 1922. This was also lower than the January, 1922, accounts by eleven, with a lowered value of $8.46.

The New York territory also decreased its accounts during the same period from 485 to 392, with an average valuation of $193 and $139 respectively. In Philadelphia the January, 1923, accounts increased from 183 in December to 212, increasing the average valuation during this period from $105.51 to $145.22. The New England accounts changed from 34 in December to 66 in January, 1923, with an average increase in valuation from $112.05 to $118.27. Conditions on the Pacific Coast have improved, since the average accounts have been lowered during this period from $153.90 to $90.60. The list of delinquent accounts is as shown above.

## The Metal Market

### Major Non-Ferrous Trade Is Active—Lead Shortage Still Acute—Copper 15⅛ Cents

The major non-ferrous metal markets continue to show much activity. Copper is quoted at 15⅛ cents; the lead shortage is as acute as it has been for many weeks, while zinc has shown a slight softness in price. The tense European situation abroad has had no perceptible effect on prices of any of these metals, and domestic business is reported highly satisfactory by nearly all metal consumers. Domestic markets have been strong enough to permit them to behave independently of Europe.

NEW YORK METAL MARKET PRICES

| | Feb. 6, 1923 Cents per Pound | Feb. 13, 1923 Cents per Pound |
|---|---|---|
| Copper | | |
| Electrolytic | 15.00–15.12½ | 15.12½ |
| Lead, Am. S. & R. price | 8.00 | 8.00 |
| Antimony | 7.50 | 7.50 |
| Nickel, ingot | 30.00 | 25.00–30.00 |
| Zinc, spot | 7.00 | 7.05 |
| Tin Straits | 39.00 | 40.00 |
| Aluminum, 98 to 99 per cent | 22.00–23.00 | 23.00 |

### Copper and Brass Products

Copper, brass and bronze mills quote the following prices on brass and copper products:

Copper wire, 17.25 cents net, mill; brass wire, 19.5 to 21.5 cents; copper sheets, 22.50 cents; copper rods, 21 cents; brass rods, 17.50 to 21.62½ cents; sheet brass, 19.25 to 20.87½ cents.

## Porcelain Insulator Market Prospects Are Bright

A survey of the porcelain insulator market shows increasing activity and bright prospects for the coming summer months. A slight spurt in sales to the utilities was noted in the trading of last month, and this continues as strong for the first two weeks in February. Jobbers in the Middle West report that they are well stocked and can make deliveries for almost any amount. In the East stocks are fair but not plentiful. Most of the inquiries in the northern sections are for smaller lots, while the line construction programs in the southern districts demand larger amounts and quicker deliveries. Manufacturers are of the opinion that orders from the central stations and telephone companies all through the United States will soon start in heavier volume, and that sales for the next three months will be somewhat larger than they were for the corresponding period of 1922.

## Healthy Demand for Washers and Cleaners

Observation of retail sales indicates that washers and cleaners are rapidly getting into the staple class of electrical merchandise and that seasonal conditions are of decreasing importance in this branch of the trade. A

slight recession in demand followed the holidays, and stocks were gradually replenished during January in many quarters. Deliveries are hampered by railroad congestion, but by and large there are no serious shortages reported in this line at the moment. Competition is extremely acute in both washer and cleaner sales. It is doubtful whether recent price movements upward have cut materially into the demand, because of the widespread convenience of deferred payments in retailing this equipment. New methods of merchandising are proving effective, and the nation-wide tendency to equip the homes of workers within the central-station industry with appliances through commercial policies offering employees advantageous terms is bearing fruit in sales. The problem of domestic labor continues acute, and the outlook is bright for the year's business in these classes of equipment.

January of 1922 will show a most gratifying increase. The railroads are introducing new cars almost daily and shipments are much improved. Industrial equipment continues to be in strong demand. Small motors particularly are moving rapidly. Building operations here have absorbed a surprising amount of wire and fixtures, while the appliance dealers have not been idle. Washers and cleaner sales have exceeded the most generous estimate. Radio jobbers and dealers are capitalizing the revival of interest in the programs. Stocks are good. Collections are fair.

# The Week in Trade

**Prices When Quoted Are Those Reported at the Opening of Business on Monday of This Week for Points West of the Mississippi River and on Tuesday for All Eastern Points**

DEMAND for electrical commodities throughout the United States is of a steady nature, stocks generally are reported normal and prices of wire and conduit are increasing. A sudden spurt in sales of materials entering into the repair and extension of central-station lines is noted. Meters are said to be selling in better volume. Motors in the smaller sizes are known to be active, most of these entering into the manufacture of fans. Commercial and residential fixture sales are increasing as a result of intensive campaigns in different parts of the country.

**Boston** Business is improving and railroad difficulties are the only serious obstacle at present to expansion of trade. Building contracts in New England during January totaled $22,770,000, a gain of 9 per cent over December and 42 per cent over January, 1922. Manufacturing continues active. Retail trade still feels the effects of severe weather. Prices are stiffening in tape and steel products. Stocks are short in rigid conduit, pole-line hardware and some sizes of small motors. Inquiries are very active this week in jobbing circles. Central stations are throwing more vigor into commercial developments and appliance sales are keeping up well. Vacuum tubes are scarce in some sizes and cross-arm purchasers are handicapped by delayed shipment conditions. Wiring contractors are extremely busy on residential work.

**New York** Business continues at a steady gait, and prospects for the coming spring months are thought to be excellent. Motors are selling actively. Renewed interest is being shown in the fixture market, where firm prices prevail. Meters during the week took on strength. Porcelain, high-tension equipment and wire also picked up considerably during the last few days. Jobbers report business a trifle better than it was the week before. Wiring contractors are busy on residential work.

**Baltimore** Demand for jobbers' stocks is reported only fair. A slight pick-up in the demand for porcelain, wire and pole-line hardware is noted. Residential and commercial fixtures are selling in better volume, and the prospects for this market during the coming summer and fall months are exceptionally bright. Stocks generally are normal and prices are firm.

**Atlanta** This section was visited by heavy sleet storms the early part of this week, resulting in heavy damage to telephone and local distribution systems and adversely affecting the high-tension lines of the power companies in Alabama. Service has been resumed, but heavy purchases will be made to replace the damaged lines. The improvement and expansion projects of the larger power companies are beginning to get under way, and this is reflected in the volume of sales. Shipments are lengthening and jobbers report low stocks in certain items. General increases in the price of copper wire and conduit are to be noted. Jobbers report business as satisfactory, and all indications point to this being a record year.

**Pittsburgh** The spirit of optimism is gradually increasing, although this is offset somewhat by the very low prices that are being quoted at some points. The work that is being given out to the electrical contractors is of a larger size in volume of dollars than for some time past. It is possible that the increase in price of various classes of material may cause a tendency to hold up some of the larger jobs. For instance, a job that was let during the past week showed that the last figures were 13 per cent higher than when figured with the materials at the lowest price. During the week conduit has again shown an increase, and it seems to be just about as scarce as ever.

**Cleveland** A decided upward trend in electrical business is evident, and it is believed that a comparison of January this year with

**Chicago** Few changes are noted. Present-day buying is steady, while a few jobbers report a seasonal slackening demand on staple materials. But all dealers are optimistic and feel that the year will bring even more business than 1922. Current demand for washing machines and vacuum cleaners has been fairly steady, the volume being determined by sales campaigns. Neither tape nor outlet boxes have given evidence of increased demand, and stocks are normal. Eastern freight embargoes are seriously worrying pole shippers.

**St. Paul-Minneapolis** Washers and cleaners are steady all around. Business is picking up a little over the slump that followed the holidays. Dealers are inclined to be conservative in buying, but city retail sales seem to be well up to normal. Agents for various lines report a steady business—not above normal, but better than was expected for this winter. Conduit boxes are active. Wiring is steady in both cities, as it has been all winter. Conduit stocks, particularly the small sizes, are still low.

**St. Louis** The building permits for the month of January, 1923, amounted to $2,560,326 against $1,119,530 for the same month in 1922, or an increase of approximately 127 per cent. It is interesting to note that while the total has increased there has been a decrease of 19 per cent in the amount of the permits issued for manufacturers and workshops as compared with that of the same month one year ago. The various motor manufacturers all report large sales in almost all lines, the orders being considerably in excess of the present production.

**Portland-Seattle** Much activity is being shown by inquiries about electrical equipment, particularly from the lumber industry. A greater program of electrical development than has been experienced for many years is either in progress now or will soon be started throughout the Northwest. Manufacturers report a slight reduction in transformer costs. The demand for large sizes is very heavy, and deliveries of them are not promised short of a period of six months.

# Demand, Supply and Price Trend of Eighteen Commodities as Sold in Sixteen Cities

Explanation:
Demand: Steady, Slow or Active
Supply: Normal, Low or High
Price Trend: Firm, Decreasing or Increasing

The local supply of distribution size transformers is normal. The demand for lead-covered cable, particularly paper-insulated, is active and deliveries cannot be obtained in less than ten months. Conduit stocks are still in a depleted condition, although new shipments are expected daily. Building construction, however, is so active that the demand for conduit continues to keep in advance of incoming stocks. A drop is reported in porcelain knobs and tubes. Prices on conduit are reported to be 5 to 10 per cent higher.

**San Francisco** Constructive efforts are being made by electrical manufacturers and jobbers to ascertain the best type of motor, cord, lighting or wiring for each particular industry. Very satisfactory are the Department of Agriculture reports of California's 1922 crop total, which constituted a record tonnage. Growers received $183,000,000 for field crops, $194,000,000 for fruit and $19,000,000 for vegetables and cantaloupes. Moreover, 1922, with nearly 15,500,000 cases, set a new record for fruit packing. These totals explain why prosperous retail conditions prevail throughout the state.

**Denver** Improved status of basic commodities is reflected in increasing electric equipment orders and in improvements and extensions to central-station service to accommodate new business. Inquiries and purchases from railroads and industrial plants are likewise increasing daily. Loca[l] jobbers' and manufacturers' stocks ar[e] meeting normal requirements, but slow deliveries rather than increases i[n] prices are preventing completion o[f] stocks for business anticipated in earl[y] spring.

**Salt Lake City** This week is "In[termountain Prod]ucts Week," and a big drive to stim[u]late interest in home products is no[w] in progress. Every department [of] manufacture is represented in th[e] campaign, and by lecture display a[nd] demonstration the economic doctrine [is] being proclaimed that local produc[ts] should have preference over their co[m]petitors, provided they offer eq[ual] value.

# Activities of the Trade

Devoted to News of the
Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

### Milwaukee's Fixture Industry Seen by Foreign Delegates

The manufacturing, jobbing, wholesaling and retailing of electrical fixtures in Milwaukee is being studied by a delegation of lighting experts from London, Paris, Shanghai and Tokio who are making tours of inspection in the leading electrical centers of the country. Included among the many electrical manufacturing concerns in Milwaukee to be visited by the delegates is the Julius Andrae & Sons Company.

### Radio Corporation Patent Suit

Judge Augustus N. Hand, in the United States District Court for the Southern District of New York, has handed down decisions in three patent suits brought by the Radio Corporation for infringement of the De Forest audion patents by the manufacture and sale of vacuum tubes for radio purposes. In all three cases Judge Hand granted preliminary injunctions asked for. The first of these suits was that of the Radio Corporation of America against La France Import & Sales Company, Inc., and others manufacturing and selling a vacuum tube known as the "La France" detector and amplifier. The second suit was against Harry Rosenthal and others who are manufacturing and selling a vacuum tube detector and amplifier known as the "Perfection" tube. The third suit was against the Radio Guild, Inc.

### Atlanta Sales District of Westinghouse Lamp Meets

The annual meeting of the Atlanta sales district of the Westinghouse Lamp Company was held in Atlanta on Feb. 1 to 3, inclusive. This district embraces the Southeastern States, and a representative attendance of executives and salesmen was reported. The meeting was featured by discussions on sales promotions through merchandising and advertising mediums and the discussions of technical problems by the company's illuminating and commercial engineers.

### Mercury Company Increases Capacity to 7,200 Trailers

By the addition of a new one-story building, 100 ft. x 60 ft., the Mercury Manufacturing Company, Chicago, will be able to turn out 7,200 electric trailers per year, according to officials of that company. This additional space was used to simplify and unify production which has resulted by the addition of only a few more men.

Total sales for the year, according to a statement made by J. R. Beansley, general manager, ran about twice that of 1921. With large industries recognizing the problem of internal transportation as one of paramount importance, Mr. Beansley expects business for the coming year will increase steadily.

### G. E. Wins Preliminary Injunction in Incandescent Lamp Suit

The General Electric Company has been granted a preliminary injunction against P. R. Mallory & Company, Portchester, N. Y., manufacturers of tungsten wire, and the Save Electric Corporation, Brooklyn, manufacturer of incandescent lamps. These injunctions are based upon the General Electric Company's broad tungsten-lamp patent of Just & Hanaman and upon the Langmuir gas-filled lamp patent. Both of these patents have been sustained by the Circuit Court of Appeals in previous litigations. The effect of these injunctions will be to prevent defendants from continuing the manufacture and sale of their products, pending the final outcome of the litigation.

### Apex of Denver to Double Force in House-to-House Campaign

The Apex Distributing Company of Denver, which since its organization a year ago has maintained headquarters in a downtown office building, has leased half of the ground floor of the new Wilda Building, at 1437 Welton Street in that city. Plans have been completed for doubling the sales force with the intention of starting a house-to-house campaign covering every corner of the city.

### Wagner Electric January Sales Showed Large Increase

January sales of the Wagner Electric Corporation are reported by the company as 90 per cent greater than those of January, 1922, and the December sales were 60 per cent in excess of those of December of the previous year. Among the important contracts recently secured by the company are the complete electrical equipment of the Missouri Portland Cement Company for its local plant improvements, the complete motor installations of the new power plant of the Union Electric Light & Power Company at Cahokia, Ill., and the motors to be used in the electrification of the local plants of the N. K. Fairbanks Company, the Benjamin Moore Paint Company and the Alton Brick Company.

### Westinghouse Receives $500,000 Railroad Order

Because of a large increase in traffic, the Long Island Railroad, which handles probably the heaviest suburban traffic in the world, has just purchased from the Westinghouse Electric & Manufacturing Company forty motor-car equipments, twenty trail-car equipments and four baggage-mail-car equipments. The baggage cars will be equipped with Westinghouse type 308 D-7 field control motors and Westinghouse electropneumatic control. In order to take care of the increase in power demand when this new equipment is put into service, it has been necessary to increase the substation capacity of the railroad, and an order has been placed, also with the Westinghouse company, for one 4,000-kw. and one 3,000-kw., six-phase, 25-cycle, 650-volt converter with the necessary transformers. The entire order amounts to over half a million dollars.

### Allis-Chalmers Net Profits in 1922 Were $2,208,549

The Allis-Chalmers Manufacturing Company, Milwaukee, Wis., manufacturer of electrical machinery, in an earnings statement for the fourth quarter of 1922, shows a net profit of $479,985.70. Sales billed amounted to $5,863,654.23. Detailed figures for the last three months of the year follow:

| | Sales Billed | Net Profit |
|---|---|---|
| October | $1,858,424.23 | $160,309.42 |
| November | 1,823,878.58 | 162,389.24 |
| December | 2,181,351.42 | 157,287.04 |
| | $5,863,654.23 | $479,985.70 |

In closing for the year 1922 there has been transferred to earnings an amount of $524,619.13, representing balance of reserves set aside in prior periods on certain contract guarantees which have since expired. These reserves are therefore now definite earnings, as is likewise $175,000 received in part settlement of a foreign contract.

The billing and net profit for the four quarters of 1922 follow:

| | Sales Billed | Net Profit |
|---|---|---|
| First quarter | $4,671,602.78 | $278,733.30 |
| Second quarter | 4,778,863.42 | 299,796.04 |
| Third quarter | 5,479,925.26 | 450,415.00 |
| Fourth quarter | 5,863,654.23 | 479,985.70 |
| Add for reserves transferred to earnings as explained above | ............ | 699,619.13 |
| | $20,794,045.69 | $2,208,549.17 |

### Reorganize Washing Machine Firm

Announcement is made that the Holland Manufacturing Company, Holland, Mich., manufacturer of electric washing machines and ironers, has been reorganized and now is known as the Holland Maid Company. The latter company has bought the land, buildings, machinery, stock and patents of the former concern, and is capitalized at $400,000.

## Foreign Trade Notes

PROPOSED RAILWAY ELECTRIFICATION IN BRAZIL.—In a message from the President of the State of São Paulo to the Congress of that state, according to *Commerce Reports*, credit to the amount of 1,297,418 milreis has been asked for the purpose of electrifying the Campos do Jordão Railway in Brazil. The railroad is a branch line, 50 miles long, extending north from Pindamonhandaba on the Central Brazil Railway. Energy to operate the road can be supplied by the São Paulo and the Rio de Janeiro electric companies. The system to be adopted will be either single-phase, 10,000 volts to 15,000 volts, or direct current at 1,200 volts to 3,000 volts.

EXTENSIONS TO THE ELECTRIC SYSTEM IN ROME, ITALY.—An appropriation of 20,569,100 lire was authorized by the Communal Council of Rome last June, according to *Commerce Reports*, for the purpose of extending the plants and system for generating and distributing electricity for the municipality of Rome. The work includes increasing the capacity of the flume at the central station of Castelmadama from a flow of 20 cu.m. to 25 cu.m. and the installation of turbo-generators at a cost of 2,500,000 lire; the erection of a 60,000-volt transmission line from Terni to Rome and a transformer station to carry the current received from the Visso station of the Alto Nera Company or from the commune's own generating station now under construction on the Nera, to cost about 12,700,000 lire; the installation of a new generator, boilers and auxiliary equipment in the central station at Montemartini, to cost 5,800,000 lire, and extension of distribution lines to furnish service to new consumers and to furnish more public lighting, at a cost of 1,500,000 lire.

## Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number.

Purchase is desired in Mexico (No. 5,349) for self-contained gasoline motor-operated electric plant for ranch house, to supply current for lamps and refrigerator, including gasoline engine, refrigerator and accessories.

Purchase and agency is desired in the Netherlands (No. 5,356) for high-grade electrical household appliances, especially washing machines, cookstoves, flatirons, teakettles, fans and refrigerators.

An agency is desired in South Africa (No. 5,358) for radio apparatus.

Purchase and agency is desired in Poland (No. 5,362) for wire for winding dynamos and apparatus for measuring electric current.

Purchase and agency is desired in Scotland (No. 5,363) for electric lamps for home and for motor cars, electric air pumps for automobiles, electric plants for home use, and wireless apparatus.

Purchase is desired in Mexico (No. 5,382) for one oil-engine generator set, 10 kw. to 12 kw., to operate on fuel oil.

An agency is desired in Norway (No. 5,402) for electrolytic copper of the usual size.

## New Apparatus and Publications

UNDERFEED STOKER.—The Sanford Riley Stoker Company, Worcester, Mass., has issued publication No. 61, describing the Jones "A-C" automatic underfeed cleaning stoker.

ELECTRIC REFRIGERATING MACHINE.—The Koldak Company, Springfield, Mass., is distributing a booklet in which it describes the new "Koldak" household electric refrigerating machine. This machine can be applied to any existing ice box.

ELECTRIC IRONER.—An electric ironer, "Du-All," has been put on the market by the Horton Manufacturing Company, Fort Wayne, Ind.

AUTOMATIC MIXER.—An improved-style mixer with the motor placed in the base has been developed by the Arnold Electric Company, Racine, Wis.

VACUUM SWEEPER.—An electric vacuum sweeper has recently been placed on the market by the Hamilton Beach Manufacturing Company, Inc., Racine, Wis.

ELECTRIC CLOTHES WASHER.—A vacuum-cup-type electric clothes washer has been developed by the Horton Manufacturing Company, Fort Wayne, Ind.

ELECTRIC DISHWASHER.—The Family Dishwasher Company, Black Earth, Wis., has placed on the market an electric dishwasher.

PUMPING COMPRESSOR.—A direct pumping compressor designed especially for gasoline filling stations has been placed on the market by the Kellogg Manufacturing Company, Rochester, N. Y.

BUFFING AND POLISHING MACHINE.—A direct-driven buffing machine equipped with roller bearings has been developed by the Cleveland Armature Works, Inc., 4,732 St. Clair Avenue, Cleveland.

SMALL TURBINE-GENERATOR SET.—The Moon Manufacturing Company, 108 North Jefferson Street, Chicago, has placed on the market a small turbine-generator set of 1½ kw. capacity.

ELECTRIC HEATER AND COOKER.—The Rogers Electric Laboratories Company, 2,015 East Sixty-fifth Street, Cleveland, has placed on the market an electric heater and cooker.

GENERATOR SET.—The Climax Engineering Company, Clinton, Iowa, has brought out a generator set consisting of a continuous-current generator directly connected to a four-cylinder gas engine, which is manufactured in sizes ranging from 15 kw. to 50 kw.

BATTERY CONTAINER.—A one-piece battery container made of an impregnated fiber composition has been placed on the market by the Ahlbell Battery Container Corporation, Waukegan, Ill.

BURGLAR-ALARM SYSTEM.—An improved burglar-alarm system has been developed by the Metropolitan Electric Protective Company, 233 Seventh Avenue, New York City.

AUTOMATIC TIME SWITCH.—An automatic time switch with an eight-day movement, designed particularly for furnishing artificial daylight in henhouses, has been developed by the A-A Manufacturing Company, 128 East Twenty-third Street, New York City.

ELECTRIC LAMPS.—The Localized Lighting Corporation of Ameleco, 540 West Fifty-eighth Street, New York City, has developed a typewriter lamp which can be attached to the back of the typewriter frame and which closes with the desk. The company has also brought out a lamp, "Han-D-Lite," which can be attached to the bed, chair or other places for concentrating the light directly on any special object.

DISHWASHER.—An electric dishwasher for the drainboard of the kitchen sink has been developed by the Milwaukee Dishwasher Company, Inc., Milwaukee.

COUNTERFEIT DETECTOR.—The Teller Manufacturing Company, 149 Broadway, New York City, has placed on the market a new electrical device, "The Teller," for the detection of counterfeit money and altered paper.

## New Incorporations

THE DORSET (VT.) ELECTRIC LIGHT COMPANY has been incorporated with a capital stock of $10,000 by Edwin Lefebvre, Ernest West, William M. Batchelder and H. N. Williams, all of Dorset.

THE CYR ELECTRIC COMPANY, Van Buren, Me., has been incorporated with a capital stock of $10,000 to generate and distribute electricity in Cyr and Hammond plantations. The officers are: Elzear Papointe, president; Napoleon Papierre, treasurer, and O'Neil Lapierre, clerk.

THE ELEZABETHTOWN (ILL.) POWER & LIGHT COMPANY has been incorporated with a capital stock of $20,000 by George W. Ledbetter, Elisha L. Robinson, Earl T. Galloway and Earl C. Gaines, Jr.

THE PEOPLE'S ELECTRIC SERVICE COMPANY, Elkader, Iowa, has been incorporated with a capital stock of $750,000 to take over the property of the Turkey River Power Company. The officers are: F. H. Schmidt, president; William Allyn, vice-president; William C. Reimer, secretary and treasurer, and E. S. Gage, manager.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

PORTLAND, ME.—Electric traveling cranes and other electric equipment will be installed at the proposed new freight terminal of the Portland Terminal Company, to cost about $1,500,000.

CLAREMONT, N. H.—At the March town meeting the proposal to install a new lighting system in the business district will be submitted to the voters. The cost is estimated at about $25,000.

BELLOWS FALLS, VT.—The installation of an ornamental lighting system in the business district, to cost about $10,000, has been authorized.

SPRINGFIELD, MASS.—Electric power equipment will be installed at the plant of the Eastern States Refrigerating Company, Bridge Street, in connection with additions and improvements, to cost about $200,000.

PITTSFIELD, MASS.—The Pittsfield Electric Company has secured permission to issue $125,000 in capital stock, the proceeds to be used for extensions and improvements.

HARTFORD, CONN.—The Standard Mattress Company, 71 North Street, plans to erect an addition to its power house.

## Middle Atlantic States

ROCHESTER, N. Y.—The Rochester Gas & Electric Corporation has petitioned the Public Service Commission for approval of franchises issued by the towns of Victor, Mendon, Henrietta and Bloomfield and the villages of Holcombe and East Bloomfield granting the company permission to extend its electric lines to furnish electricity in those places. If the petitions are granted, the company plans to erect 12 miles of line in Henrietta and 8 miles in Holcombe and East Bloomfield. Contracts have already been drawn up for street-lighting systems in both towns.

SYRACUSE, N. Y.—Work will begin as soon as the weather permits on the construction of a new power house for the Crouse-Irving Hospital, to cost about $40,000. Dr. W. L. Wallace is the head of the institution.

BERKELEY HEIGHTS, N. J.—Electric power equipment will be installed at the local cold-storage insulation manufacturing plant of the J. H. Stone Corporation, in connection with rebuilding the portion recently destroyed by fire. The loss is estimated at $150,000.

ROOSEVELT, N. J.—Electric power equipment will be installed at the local plant of the Armour Fertilizer Works, 209 West Jackson Boulevard, Chicago, in connection with rebuilding of the portion recently destroyed by fire with loss estimated at $75,000.

BERNVILLE, PA.—The property of the Bernville Electric Light, Heat & Power Company has been purchased by Shower Brothers. The new owners, it is understood, will make extensive improvements to the system.

HOLTWOOD, PA.—Investigations, it is reported, are being made by the Pennsylvania Water & Power Company in connection with the construction of two additional hydro-electric generating units. The cost is estimated at $750,000.

INDIANA, PA.—E. G. House, operating the coal properties of the Manufacturers' Coal Company, Yellow Creek section, is planning to install electric power and mechanical equipment.

KEPLERS, PA.—The Binney & Smith Company, 41 East Forty-second Street, New York, is taking bids for the installation of a power house at its local plant. Lockwood, Greene & Company, 101 Park Avenue, New York, are engineers.

NANTICOKE, PA.—The Susquehanna Collieries Company, Commercial Trust Building, Philadelphia, will install electric power equipment in connection with the rebuilding of its local coal breaker, recently destroyed by fire, causing a loss of about $750,000.

FAYETTEVILLE, PA.—The plant of the Fayetteville Electric Light & Power Company has been purchased by the Potomac Public Service Company, Hagerstown, Md. The new owner will take possession June 1.

PITTSBURGH, PA.—The Duquesne Light Company has secured permission to acquire the following companies: Avalo Light, Ben Avon Light, Robinson Township Light, Neville Township Light, Emsworth Township Light, Stowe Township Light, Bellevue Light, Kennedy Township Light, Kilbuck Township Light, Haysville Light, Glenfield Light and Coraopolis Light companies. Extensions and improvements will be made to the systems.

PHILADELPHIA, PA.—Bids will be received by the United States Engineer Office, 815 Witherspoon Building, until Feb. 23 for one Diesel engine, with accessories and spare parts.

PHILADELPHIA, PA.—The Philadelphia Suburban Gas & Electric Company, West Washington Square, has issued $650,000 in bonds, part of the proceeds to be used for extensions in the Cromby electric plant, to increase the capacity from 10,000 kw. to 20,000 kw.

ANNAPOLIS, MD.—The Annapolis Public Utilities Company has been granted permission to change its name to the Severn Light & Power Company and extend its plants and system. Bonds for $700,000 will be issued, part of the proceeds to be used for the acquisition of plants at Laurel and Bowie and for additions and improvements to same.

BALTIMORE, MD.—The Baltimore & Ohio Railroad Company will install electric power equipment at its proposed grain elevator in the Locust Point section, to cost $4,000,000.

CUMBERLAND, MD.—The American Water Works & Electric Company has secured permission to acquire the Cumberland Edison Power Company. Extensions will be made to the plant and system.

ELKTON, MD.—The Susquehanna Power Company is preparing plans for the construction of a hydro-electric power plant at Conowingo, on the Susquehanna River, to cost about $600,000.

HAGERSTOWN, MD.—The Pennsylvania Railroad Company will electrify its local engine terminals.

BECKLEY, W. VA.—The installation of an ornamental lighting system on Main Street is under consideration. W. L. Foster is manager of the Beckley Electric Light & Power Company.

HUNTINGTON, W. VA.—The Mountain State Coal & Gas Syndicate, recently formed with a capital of $2,000,000, will install electric power and mechanical equipment at its local properties. Thomas W. Jones, Middleport, Ohio, is president.

RAINELLE, W. VA.—The East Rainelle Light & Power Company will build a transmission line from Rainelle to East Rainelle, to cost about $15,000.

FREDERICKSBURG, VA.—The Spottsylvania Power Company is planning to construct an auxiliary generating plant with initial capacity of 1,000 hp., using Diesel engines.

NORFOLK, VA.—Plans are being considered for replacing the present arch lamps on Granby, Main and Church Streets with pedestal lamps.

WASHINGTON, D. C.—Bids will be received by the Bureau of Supplies and Accounts, Navy Department, until Feb. 27 for 4,200 ft. electric wire for the Mare Island Navy Yard (Schedule 465); for 1,000 ft. single conductor lighting and power wire for the Philadelphia Navy Yard (Schedule 487); also until Feb. 20 for 1,600 ft. of rubber-covered cable for the Hampton Roads Navy Yard (Schedule 182).

## North Central States

BAD AXE, MICH.—The Great Lakes Power Company plans to erect a transmission system to cover 175 miles, to cost about $500,000. Power will be furnished by the Marysville plant of the Detroit Edison Company.

BYRON CENTER, MICH.—The Wyoming Light & Power Company contemplates extending its service to Byron Center during 1923, provided that a right-of-way for a transmission line can be obtained between Byron Center and Wyoming Park.

ISHPEMING, MICH.—The Michigan Gas & Electric Company it is reported, will soon ask for bids for equipment for its proposed hydro-electric plant to be erected on the St. Joe River, near Mottville, to cost about $400,000. Holland, Ackerman & Holland, 53 West Jackson Boulevard, Chicago, are engineers.

AKRON, OHIO.—The Northern Ohio Traction & Light Company is planning to erect two new substations, one at Akron and the other in Ravenna.

CLEVELAND, OHIO.—Bids will be received at the office of the commissioner of purchases and supplies, City Hall, until March 2 for substation switching equipment.

CLEVELAND, OHIO.—Bids will be received at the office of the commissioner of purchases and supplies, City Hall, Cleveland, until Feb. 23 for one steam-jet ash conveyor and one 40-ton ash storage tank at the City Hospital.

CHICAGO, ILL.—The South Side Laundry Company, 2820 South Wabash Avenue, will build a power plant at its works, to cost $75,000. Ronnenberg, Pierce & Hauber, 10 South La Salle Street, are architects.

FORRESTON, ILL.—The Illinois Central Railroad Company, 135 East Eleventh Place, Chicago, has completed plans for the construction of a local power plant, to cost about $80,000.

OTTAWA, ILL.—The National Plate Glass Company, General Motors Building, Detroit, will build a power house in connection with proposed extension to its local plant, known as the Federal Plate Glass Company, to cost about $5,000,000.

PEORIA, ILL.—The Central Illinois Light Company is preparing plans for an electric power plant, to cost about $2,000,000.

GREEN BAY, WIS.—The Wisconsin Public Service Corporation, which is building an 8,000-hp. hydro-electric plant at High Falls, near Pound, it is stated, will begin work about April 1 on a hydro-electric development of the same capacity at Cauldron Falls, 10 miles north of the High Falls plant.

LA CROSSE, WIS.—Plans are being prepared by O. A. Merman, architect, Linker Building, for a power house, to cost about $125,000, and also for a nurses' home for the Lutheran Hospital.

LA POINTE, WIS.—Steps have been taken to organize a company, to be capitalized at $10,000, for the purpose of furnishing electricity for lamps and motors in La Pointe and nearby places. One of the first extensions contemplated is to supply electric service to Madelaine Island. Electricity will be purchased from a power plant for which plans are under way.

LUCK, WIS.—The Railroad Commission has granted the Luck Light & Power Company permission to issue $15,000 in capital stock, the proceeds to be used to purchase the local electric plant and system, owned by Anton K. Pederson, and for extensions to same.

MILWAUKEE, WIS.—The Pittsburgh Plate Glass Company has engaged Cahill & Douglas, consulting engineers, 217 West Water Street, Milwaukee, to prepare plans for a steam-driven electric generating plant, to cost about $135,000, for the Patton-Pitcairn division of the company. The equipment will include generators, engines, boilers, automatic stokers, fuel and ash-handling equipment, etc.

OCONTO, WIS.—The Northeastern Power Company, recently organized, has applied to the Railroad Commission for permission to issue $120,000 in capital stock for the purpose of acquiring the properties of the Oconto Service Company and the Peshtigo (Wis.) Electric Company.

OWEN, WIS.—Bids will be received by C. L. Johnson, village clerk, until Feb. 21 for an ornamental street-lighting system, to include 30 lamps, in connection with street paving. The Universal Engineering Company, Eau Claire, is engineer.

SUPERIOR, WIS.—At an election to be held April 3 the proposal to purchase the electric plant of the Superior Water, Light & Power Company, to be owned and operated by the municipality, will be submitted to the voters.

VIRGINIA, MINN.—The Water and Light Commission has applied to the Council for authority to issue certificates of indebtedness to the amount of $125,000 for the purpose of installing additional boilers in the water and light plant.

HIBBING, MINN.—The Oliver Iron Mining Company, Duluth, will install electric power equipment in connection with its proposed local screening and crushing plant, to cost about $600,000.

DES MOINES, IOWA.—A two-story heating plant, power house and laundry, to cost about $100,000, will be erected at the Methodist Hospital this year.

LE MARS, IOWA.—The Board of County Supervisors has granted the Iowa Light, Heat & Power Company permission to erect a transmission line from the town of Le Mars to Merrill.

SIOUX CITY, IOWA.—Tentative plans are under consideration by the Sioux City Gas & Electric Company for the construction of a new power plant, to cost between $2,000,000 and $2,500,000.

HOLDEN, MO.—Electrically operated pumping machinery will be installed in connection with improvements to the municipal waterworks system, to cost about $80,000. The Benham Engineering Company, Gumbel Building, Kansas City, Mo., is engineer.

POPLAR BLUFF, MO.—Electric power equipment will be installed in the proposed new ice-manufacturing plant, to have a capacity of 100 tons daily. F. A. Bacon is president.

SHERIDAN, MO.—The Maryville (Mo.) Electric Light & Power Company is planning to extend its transmission line from Parnell to Sheridan to furnish electrical service here.

BEATRICE, NEB.—The Black Brothers Company will build a hydro-electric power plant in the Blue Springs section for flour-mill and other industrial service, to cost $100,000.

PLATTSMOUTH, NEB.—Bids will be received by A. H. Duxbury, city clerk, for installation of an ornamental street-lighting system, to include seventy-one electroliers. Bruce & Grupe, Finance Building, Omaha, are engineers.

DIGHTON, KAN.—The City Council is considering the question of erecting a transmission line to connect with the municipal electric plant at Scott City to secure electricity to operate the local system.

PARSONS, KAN.—The Kansas Gas & Electric Company, Wichita, has started work on the erection of a power plant on the Neosho River, 10 miles from Parsons.

## Southern States

AHOSKIE, N. C.—The Town Council has contracted with a number of towns to supply electricity from the municipal electric light plant. The towns that are to secure the service will erect the transmission lines to the local plant.

MOUNT AIRY, N. C.—The North Carolina Granite Company is making inquiries for an engine-generator set of about 100 kw. capacity.

WADESBORO, N. C.—Plans for the new textile mill to be erected by L. D. Robinson, at a cost of $400,000, provide for a power plant.

BELTON, S. C.—The installation of an ornamental lighting system is under consideration.

GREER, S. C.—Plans are under way for extensions in the municipal electric plant to cost $10,000.

ATLANTA, GA.—The Southern Bell Telephone Company plans extensive improvements to its local system during 1923, to cost about $1,277,000, the larger portion of which will be used for laying underground and aërial cables to care for several thousand new applications for service.

DAVISBORO, GA.—The W. G. Warthen Produce Company will install a power house in connection with proposed plant extensions.

MILLTOWN, GA.—Steps have been taken to organize a company to be known as the Lanier County Power Company. The company will be capitalized at $300,000 and proposes to build a power plant at the foot of Lake Irma in Milltown. The cost is estimated at about $200,000. F. E. Hatch is interested in the company.

MIAMI, FLA.—The installation of an ornamental lighting system on Southeast Second Street and Southeast Second Avenue is under consideration.

JACKSONVILLE, FLA.—The City Council has passed an ordinance for extensions to the municipal electric plant, to cost $850,000. The ordinance provides for an expenditure of $250,000 in 1924, 1925 and 1926. Bids, it is understood, will soon be asked for. At present funds to the amount of $100,000 are available for the work.

CHATTANOOGA, TENN.—The Dixie Portland Cement Company will install electric power equipment at its plant in connection with additions to cost about $200,000.

JONESBORO, TENN.—Repairs will be made to the local substation of the Tennessee Eastern Electric Company recently damaged by fire. The loss is estimated at about $25,000.

NASHVILLE, TENN.—Bids will be received at the United States Engineer's office, Nashville, Tenn., until March 6 for one electric towboat.

ALICEVILLE, ALA.—The Pickens County Light & Power Company, recently organized, plans to install a power plant and system for local commercial service. J. V. Park is president.

EAST BIRMINGHAM, ALA.—The George C. Brown Company, Huntsville, Ala., plans to install a power house at its proposed local veneer plant, to cost about $100,000.

GLENDALE, ALA. — J. J. Harrison & Company, Florala, Ala., plan to install a street-lighting system in connection with the development of a 600-acre tract of land.

MONROEVILLE, ALA.—Extensions will be made in the municipal electric power plant, including the installation of new equipment.

GULFPORT, MISS.—The installation of an ornamental lighting system, covering twelve blocks, is under consideration by the city commissioner.

GULFPORT, MISS.—Bids will be received at the Bureau of Yards and Docks, Navy Department, Washington, D. C., until Feb. 26 for the installation of electric lighting systems for each building; power and telephone conduits; outside electric distributing systems, including transformers, panelboards, fixtures, conduits, fiber conduits and wiring, at the United States Veterans' Hospital, Gulfport. (Specification No. 4,771, part IV.)

OKMULGEE, OKLA.—Electrically operated pumping machinery will be installed in connection with extensions and improvements to the municipal waterworks system, to cost about $150,000. T. J. Embree, Okmulgee, is engineer.

PONCA CITY, OKLA. — The Marland Refining Company will install electric power equipment at its local oil refinery in connection with proposed extensions.

TONKAWA, OKLA. — The Comar Oil Company will install electric power equipment at its proposed local refining plant, to cost about $150,000.

PORT ARTHUR, TEX.—A power house will be erected by the Atlantic Refining Company, 3144 Passyunk Avenue, Philadelphia, in connection with its proposed new oil refining plant, to cost about $500,000.

SAN ANTONIO, TEX.—C. H. Alexander, 612 Houston Building, and associates plan to install a hydro-electric power plant. Inquiries are being made for waterwheels, generators, etc.

TAYLOR, TEX.—Plans are being prepared for the installation of an ornamental lighting system in the business section.

TEXAS CITY, TEX.—The Texas Refining Company, recently organized, will install a power house in connection with its proposed local refinery, to cost about $1,500,000. Alexander Smith, of Peabody, Houghteling & Company, 366 Madison Avenue, New York, bankers, is president.

SNYDER, TEX. — The Snyder Utilities Company contemplates additions and improvements to its power plant and system, to cost about $50,000.

## Pacific and Mountain States

BATTLEGROUND, WASH.—The Clarke County Light & Power Company plans to install a power plant and system for local commercial service.

HOQUIAM, WASH.—The Grindle Canning Company contemplates the installation of a one-story power house at its plant.

SPOKANE, WASH. — The Washington Water Power Company is planning extensions to its hydro-electric plant at Long Lake to increase the output by 22,500 kw., at a cost of about $250,000.

WALTERVILLE, ORE.—Extensions and improvements to the municipal electric light plant are under consideration by the Water Board. Cary A. McClair is manager.

IGO, CAL. — The California Bimetallic Company, operating local silver mines, will build a transmission line for electric service at its plant, to cost about $30,000.

OAKLAND, CAL.—The Neilson Packing Company will install electric power equipment at its proposed fruit-packing and refrigerating plant on Ninety-ninth Avenue, to cost about $300,000.

SANTA BARBARA, CAL.—The Southern California Edison Company will build a steel-tower transmission line in the Montecito section, 22 miles, to cost $200,000. Improvements will be made in the distributing system at Hanford, to cost $60,000.

SUSANVILLE, CAL.—The construction of an electrically operated railroad, 15 miles long, in the Eagle Lake section, for the purpose of hauling logs to sawmill, is under consideration by the Fruit Growers' Supply Company, First National Bank Building, San Francisco. Electricity to operate the proposed railway would be obtained from the local plant of the Lassen Electric Company.

ADAIR, IDAHO. — Extensions will be made to the power plant of the Montana-Idaho Power Company, to cost about $20,000. The output will be increased from 90 hp. to 250 hp.

NOGALES, ARIZ.—The Southern Arizona Power Company has been organized to take over and merge the Nogales Electric Light & Power Company and the Arizona Gas & Power Company. Extensions will be made in power plants and transmission systems.

DILLON, MONT.—The Union Electric Company has contracted with the Beaverhead Transmission Company for power supply. A 66,000-volt transmission line will be erected.

ALAMOSA, COL. — Work will soon be started on improvements to the local plant of the Colorado Power Company. New equipment, including a 750-kw. turbo-generator, new condenser and automatic stokers, will be installed.

DENVER, COL.—The United States District Court has ordered Ernest Stenger, receiver of the Denver Tramway Company, to purchase machinery and equipment for the main power plant of the company, the cost not to exceed $215,000.

MANITOU, COL.—The installation of an ornamental lighting system is under consideration by the Board of Trustees.

## Canada

COBALT, ONT.—Work will be started early in the spring by the Canadian Associated Goldfields on completing the development of its Windego Falls power scheme on the Blanche River, south of the Kirkfield field.

HAMILTON, ONT. — Surveys are being made by the Dominion & Power Transmission for a 5-mile, single-track electric railway from Hamilton to McKittrick Survey.

TORONTO, ONT.—The property committee has instructed Commissioner Chisholm to submit a report and estimate of cost of installing gooseneck standards mounted with nitrogen lamps on all main thoroughfares.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued Jan. 30, 1923)

1,443,439. Process and Apparatus for Introducing Electric Energy Into a Space of Action; G. T. Southgate, Washington, D. C. App. filed March 8, 1922. Electric furnace in which material acts as electrode.

1,443,451. Measured-Service Telephone System; A. Anderson, Chicago, Ill. App. filed Dec. 30, 1913. Automatically indicates elapse of talking time on automatic system.

1,443,469. Rheostat; J. Guthrie, Elyria, and J. W. Simmons, Cleveland, Ohio. App. filed Aug. 4, 1922. Carbon-pile resistance for vacuum-tube filament control.

1,443,494. Telephone Automatic Trunking Apparatus; T. G. Martin, Chicago, Ill. App. filed Jan. 17, 1907. Automatic trunk-selecting switch.

1,443,499. Brush Rigging; H. S. Pardee, Chicago, Ill. App. filed April 22, 1920. Single frame holds two sets of brushes 180 electrical degrees apart.

1,443,580. Electric Furnace; G. M. Little, Pittsburgh, Pa. App. filed March 23, 1921. Maintaining temperature of 2,500 deg. C. in resistor furnace.

1,443,581. Electric Resistance Tubular Furnace; G. M. Little, Pittsburgh, Pa. App. filed March 23, 1921. Employed to give green resistance rods initial baking.

1,443,583. Electrical Protective Device; P. MacGahan, Pittsburgh, Pa. App. filed March 13, 1918. Overload-protection relay.

1,443,590. Method of Supporting Resistor Mounting Plates; T. A. Reid, Pittsburgh, Pa. App. filed March 30, 1921. Electric resistance furnaces.

1,443,604. Jack Switch; E. E. Yaxley, Chicago, Ill. App. filed Oct. 16, 1922. Telephone cord jack.

1,443,613. Detective and Protective Device for Electric Cables; C. J. Beaver, Hale, A. F. W. Richards, Brooklands, and E. A. Claremont, High Legh, England. App. filed Oct. 30, 1919. Metal shielding between conductors provided at joints.

1,443,620. Telephone Transmitter; R. A. Engler, Evanston, Ill. App. filed June 23, 1919. Transmitter can be used in both wired and wireless telephony.

1,443,644. Rotary Electric Machine; K. Nobuhara, Muko-Gun, Hyogo-Ken, Japan. App. filed April 13, 1918. Cooling liquid in both stator and rotor but forced out of clearance space by gas.

1,443,645. Automatic Telephone System; W. T. Powell, Rochester, N. Y. App. filed Feb. 18, 1920. Talking connection extended through trunking switch individual to each line.

1,443,646. Automatic Telephone System; W. T. Powell, Rochester, N. Y. App. filed March 8, 1920. Conversational circuit extends only through non-numerical switches.

1,443,657. Insulator; L. Steinberger, Brooklyn, N. Y. App. filed Nov. 23, 1917. Different electrostatic capacity of successive units whereby more uniform distribution of stress is secured.

1,443,669. Electrical Connection; J. M. Andersen, Boston, Mass. App. filed April 4, 1921. Connection of apparatus to laminated busbars.

1,443,748. Lighting Fixture; W. R. Kahns and Karl Keller, Brooklyn, N. Y. App. filed March 28 1922. Portable lamp provided with shade that may be raised and adjustable sockets.

1,443,763. Circuit Maker and Breaker; G. L. Smith, Washington, D. C. App. filed May 10, 1920. Motor-vehicle signaling apparatus.

1,443,766. Control System for Electric Elevators; W. S. Smith, Cambridge, Mass. App. filed Aug. 3, 1918. Dual-control system, one automatic, the other manual.

1,443,797. Electrolytic Cell; C. W. Marsh, Greenwich Conn. App. filed Dec. 19, 1919. Construction of U and V type cells.

1,443,798. Welder's Tongs; R. Mattice, Philadelphia, Pa. App. filed July 7, 1921. Current cable fastened to handle end and passed down through center of tongs.

1,443,816. Electric Furnace; F. A. Fitzgerald, Niagara Falls, N. Y. App. filed Jan. 13, 1921. Arc type heated by radiation from single-phase arc.

1,443,873. Multiple-Roller Electric Transmission Trolley; G. Donham, Oakland, Cal. App. filed Dec. 20, 1921. Trolley collector made up of five wheels.

1,443,935. Resinous Product; L. Weisberg, Grantwood, N. J. App. filed Sept. 24, 1921. For molded insulating material.

1,443,936. Process of Making a Molding Composition; L. Weisberg, Grantwood, N. J. App. filed Sept. 24, 1921. Mixture of glycerol-polybasic acid resin and shellac.

(Issued Feb. 6, 1923)

1,443,984. Repeater Apparatus for Carrier Systems; L. Espenschied, Hollis, N. Y. App. filed June 19, 1919. Special high-frequency repeater operates in parallel with low-frequency repeater of communication line.

1,443,985. Signaling System; L. Espenschied, Hollis, N. Y. App. filed June 21, 1919. Simultaneous transmission and reception of radio signals by employing carrier waves of different frequency.

1,444,000. Electric Switch; H. J. Morey, Syracuse, N. Y. App. filed Oct. 4, 1918. Pull-chain lamp socket.

1,444,057. Grip Conduit for Electric Conductors; M. W. Bosley, Baltimore, Md. App. filed Jan. 20, 1921. Wooden moldings for house wiring.

1,444,084. Distributing Brush Holder for Magnetos with Two Simultaneous Sparks; P. J. R. Postel-Vinay, Paris, France. App. filed March 6, 1921.

1,444,113. Process for Plating on Non-Metallic Surfaces; E. F. Dietrich, Chicago, Ill. App. filed May 20, 1922. Metals permanently deposited on non-metallic surfaces by electroplating bath.

1,444,211. Time Recorder; T. Ross, Chicago, Ill. App. filed April 1, 1921. Driving and setting mechanisms of time recorders.

1,444,242. Spacing Appliance; A. A. Faust, Detroit, Mich. App. filed Aug. 11, 1921. Control of metal-working machines.

1,444,267. Electric Lantern; A. A. Pearson, Portland, Ore. App. filed Oct. 12, 1921. Adapted to railroad-yard work.

1,444,286. Means for Controlling and Regulating Electric Currents; T. L. Vaughn, Jr., Dunn, N. C. App. filed Nov. 30, 1921. Constant-voltage regulator for a group of lights.

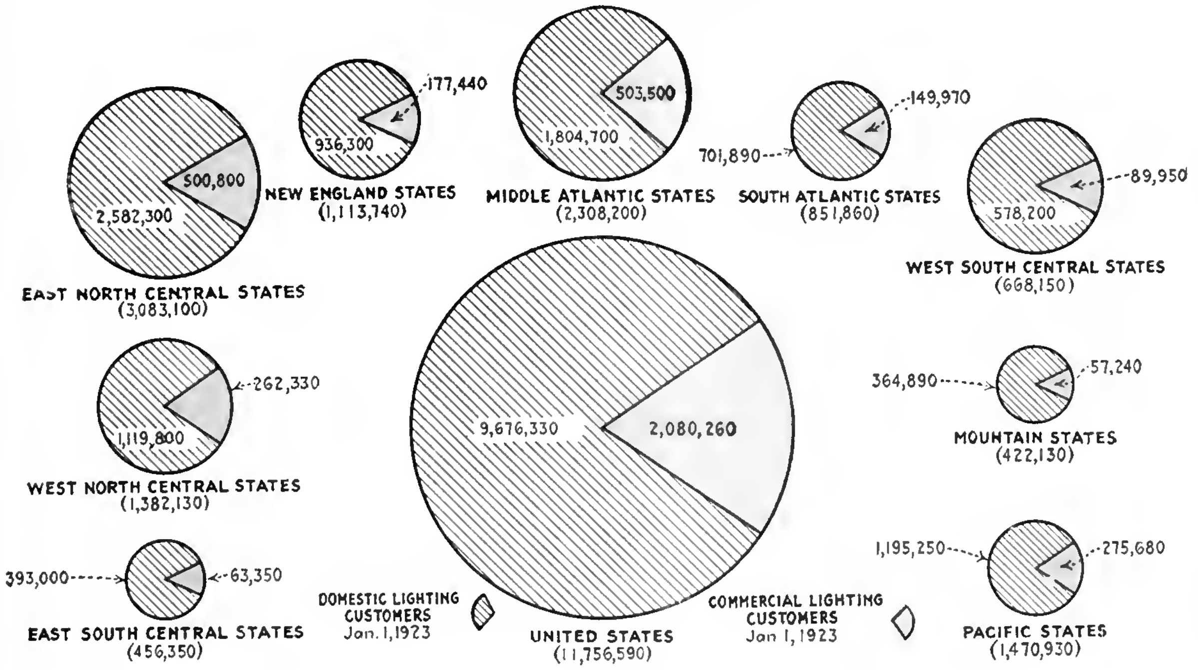
1,444,363. Brush-Holder Retainer; R. N. Baylis, Bloomfield, N. J. App. filed June 7, 1922. Pressed metal holder.

1,444,417. Multiplex System in Teledynamic Control; J. H. Hammond, Jr., Gloucester, Mass. App. filed Oct. 17, 1917. System for controlling several devices selectively from distance in response to radiant energy.

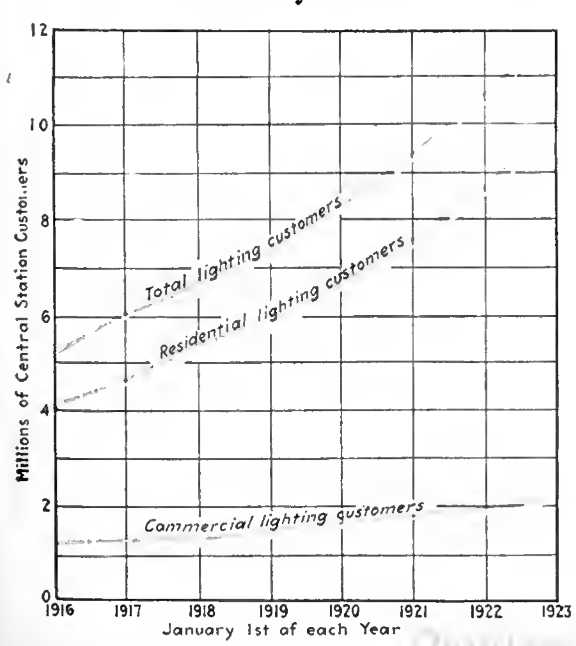
# Business Facts for Electrical Men

Selected Statistics Presented Graphically for the Use of All Interested in Analyzing the Trend of the Electrical Business

## Distribution of Central-Station Lighting Customers on Jan. 1, 1923—Comparison of Domestic and Commercial Lighting Customers by Sections



## Rate of Growth in Number of Lighting Customers Has Increased Year by Year

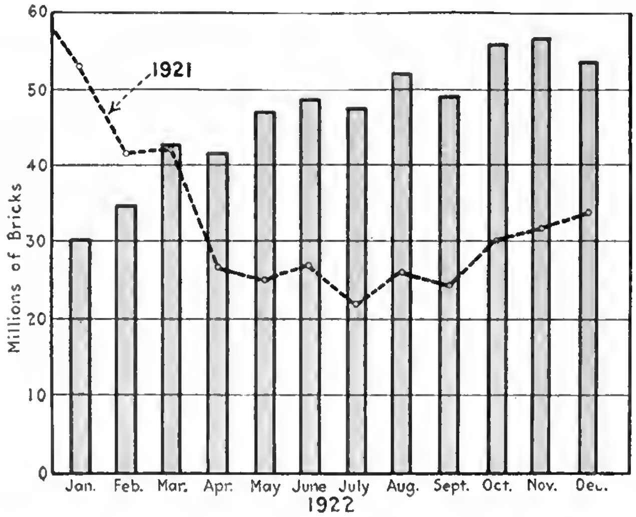


## The Significance of Growth

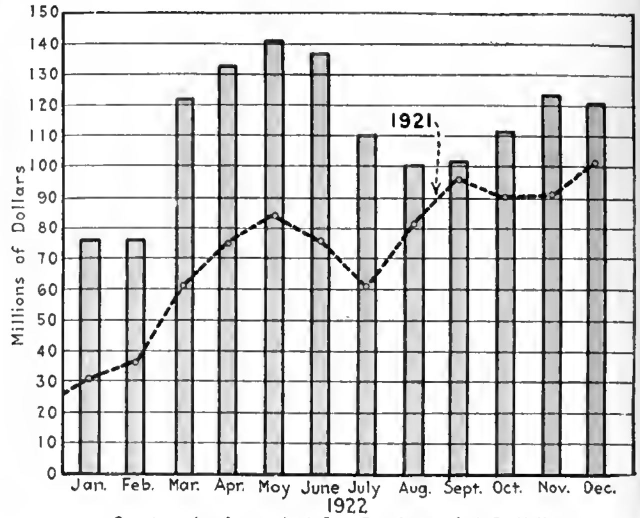
INDUSTRY grows in two ways. There is mushroom growth — an industry springs up over night as a result of some great and immediate economic need and sinks to comparatively small operations or into total oblivion after the emergency has passed. The world war brought many instances of this type of growth.

Then there is the development that is a cautious but steady advance — industry builded upon a carefully laid foundation and gradually intertwining itself into the very economic fabric of the country. Industry so buttressed will endure as long as the nation itself. And of such is the electric light and power industry. In age a mere infant among other primary industries, it has taken its place in the front rank of great enterprises and challenges all others in the service it is rendering to humanity.

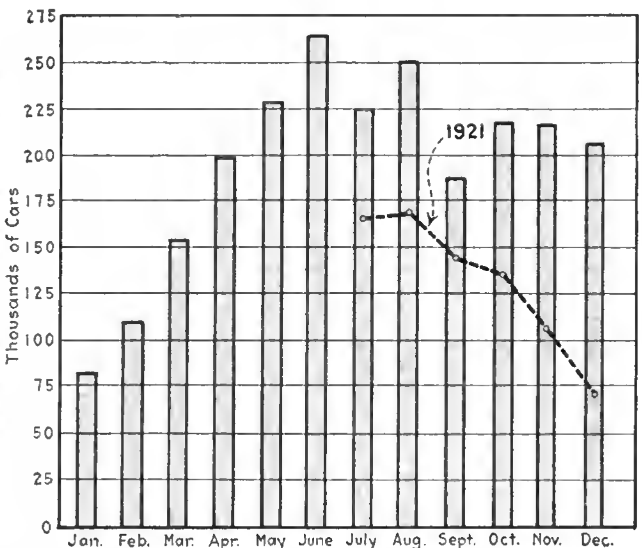
## How the Primary Industries Are Trending



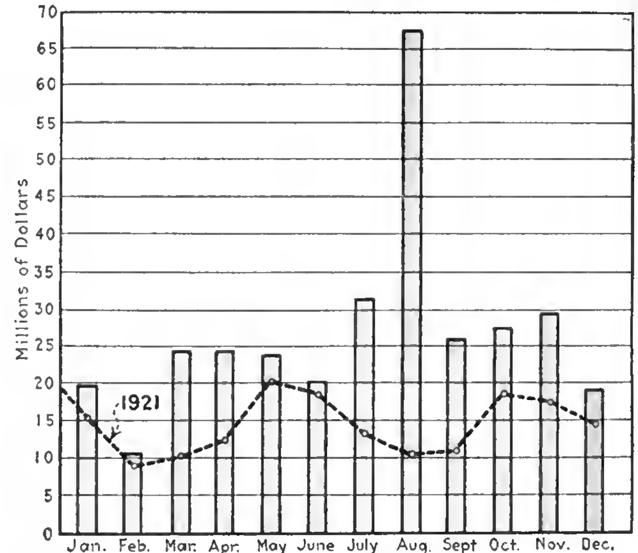
1922
Clay Fire Brick Production



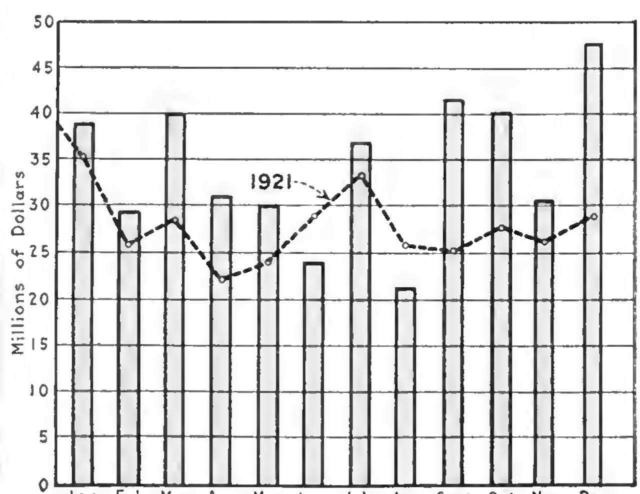
1922
Contracts Awarded for Residential Buildings



1922
Passenger Automobile Production



1922
Contracts Awarded for Industrial Buildings



1922
Fire Losses

## They All Agree

A STUDY of the prognostications of various statistical and economic bureaus on business conditions for 1923 bring out most vividly the optimism which is so prevalent in the business world today. All these students of economic trends agree that as a result of "the soundness of basic conditions and the strength of the favorable economic forces" business will continue to grow in volume at least during the first half of the year. The Harvard University Committee on Economic Research sums up the situation by the prediction of "further increase of wholesale commodity prices and continued expansion of business activity during the first half of 1923, with a strong probability that the upward swing will continue during the second half of the year."

# "Say It with Facts!"

BLESSED be the man who thinks and talks with facts! He is needed in the world today, where more time is being wasted and more money spent by doing things wrong than by not doing them at all. To the man with facts life offers greater resources, greater responsibilities and more satisfying achievements than at any period in history.

We are an impetuous generation. We like to make decisions, to set tasks and see them soon disposed of. Yet success depends on judgment, and, after all, judgment is only analysis of facts. Good facts produce good judgment. Therefore the man who gathers facts and gives them active use has knowledge and judgment superior to that of better minds that may rely on personal memory and experience. For he then has the guidance of the experience of all men.

TIME was when a man's personal observation was a pretty good guide to his work. His environment was small. His contact was limited to a few immediate influences. His work concerned himself and the few folk about him. His powers and his purposes were puny in contrast with the complex relationships of modern life. He could decide things on his own knowledge, for what he did was little to the world beyond.

But cottage industries are gone and village life is now expanded into national life, and local trade has come to be a very part of the commerce that serves all peoples and is affected by unseen conditions of far origin. Thus business has grown beyond the art and craft into a science, and when we say a science we mean that it is now founded on and sustained by facts. And there has grown up in the service of industry a great group of engineers, whose function it is to evolve, interpret, and apply these facts, by trained scientific thinking.

ANY modern industrial enterprise is like a ship at sea. The sea captain cannot look beyond the horizon, and so he uses maps of coast lines, readings of the sun, charts of winds and currents, laws of storms, his knowledge of his engines and his ship and makes decisions in accordance with these fundamental facts. The business executive ashore needs facts no less. But the situation lacks the element of personal risk, and so he and his men neglect to set a daily course by facts. They are inclined to guess and drift.

The electrical manufacturer and jobber, the central station, the contractor and dealer are all suffering today from lack of facts—facts on their cost of doing business, facts on the growth of market, facts on the value of different kinds of business, facts on competitive production, facts on distribution, facts on the relation of other primary industries to their own—all facts needed to help them serve. These facts must be sought out, compiled and made available that we may organize this mighty resource into each man's hourly work.

"Say it with facts!" It makes a good slogan. But the great need is first to get in hand more of these essential facts to think with. And for this vital contribution, industry looks to the engineer.

# George E. Quinan

*An authority on rural distribution and on safety codes governing transmission and distribution.*

ONE of the most important problems of power development in a sparsely settled country is that of rural distribution. As an authority on this subject as well as in the general field of safety codes governing transmission and distribution lines George E. Quinan, chief electrical engineer of the Puget Sound Power & Light Company, has a reputation equaled by that of few men. As chairman of various committees and a member of others in the National Electric Light Association and the Northwest Electric Light and Power Association, he has helped to direct both practices and policies along these lines.

Mr. Quinan was a graduate from the University of California with the class of 1903. Even at that time he had shown much ability as an original thinker in handling technical problems. He spent two years in general field work, in Spokane, Cœur d'Alène and on Puget Sound, helping to bring in the power from Spokane Falls which was to replace steam in the silver-lead mines of Idaho. In February, 1905, he became assistant superintendent of power with the Tacoma Railway & Power Company and the Puget Sound Electric Railway.

In 1911 he became the operating superintendent of the Seattle Electric Company's properties in Seattle. Two years later he advanced to the position of superintendent of light and power with the Puget Sound Traction, Light & Power Company, Seattle division, and two years after that he was engineer of the same organization. In July, 1919, he entered on his present duties as chief electrical engineer of the Puget Sound Power & Light Company, which controls all Washington State properties under the management of Stone & Webster.

Mr. Quinan has been a student of rates for electric service, particularly in their relation to costs. He has given considerable attention to regulatory codes relating to electrical construction, also to the inductive-co-ordination problem and the economic principles underlying the extension of service to rural communities, and is today working with others toward a solution of these problems. Among his recent interests has been the development of an alternating-current underground system of distribution in Seattle.

Mr. Quinan has had an active part in the preparation and development of accounting classifications. He was associated in the design and construction of the first plant in the West for burning pulverized coal under steam boilers. He is a fellow of the American Institute of Electrical Engineers, of which he has also served as local chairman.

# Editorial Comment

Electrical World, February 24, 1923

Volume 81

Number 8

## A Government Department Wakes Up

NOTWITHSTANDING all the work that has been done by the Illuminating Engineering Society and by others in the formulation of lighting codes, higher intensities of illumination are still the exception rather than the rule. Business people recognize the value of good lighting, and it is not uncommon to find show windows and stores well illuminated. Eight states have adopted factory lighting codes stipulating the minimum foot-candles required as a matter of safety in industrial plants, but municipal, state and national governments are slow to move. Street lighting, for instance, is far from adequate, although it is the one service that benefits every taxpayer. However, there is balm in Gilead. A ray of light has penetrated the Post Office Department and brought with it a consciousness of the economic advantages of increased illumination.

By the adoption of a standard system it was discovered that the efficiency of the postal workers was increased 4.4 per cent. It is therefore recommended that the Postmaster-General install this standard system of lighting in all post offices. If universally adopted throughout the United States postal system, the new lighting rule will effect a saving running into millions of dollars. We are not, however, so much concerned about this sudden manifestation of thrift on the part of the Post Office Department as we are about its recognition of the principles of proper illumination. Let us hope that this recognition will percolate through to other departments of the national government and on through state and municipal governments, so that the general average of civic illumination throughout the country will be heightened considerably. Certainly better illumination is sorely needed.

## Midwinter Convention of A. I. E. E. a Splendid Success

THE midwinter convention of the American Institute of Electrical Engineers has established itself as an occasion for interpreting and presenting to the electrical fraternity new discoveries and accomplishments in the theoretical aspects of electrical engineering. The convention of last week exceeded those of the past in the numbers attending, in the interest aroused by the program, in the diversity of subjects and in the number of papers presented.

Apparently there has been a rejuvenescence of interest in the theory of electricity, which can be attributed largely to the fact that the practical problems now facing the engineers in their larger engineering projects call for advanced theoretical knowledge to bring about their correct and economical solution. In many branches of the electrical industry renewed activity is noticed, and the effect of the war and the industrial depression no longer limit expansion and progress.

Conventions such as this which serve to interpret, to apply and to record technical advances in the art, and which strive to stimulate research through rendering public homage to the specialists, are valuable to the electrical industry in even greater degree than those which exist for social purposes or for discussing commercial or engineering practices. All who attended the midwinter convention must necessarily have been stimulated and keyed to a higher pitch through meeting the leading specialists in the industry and hearing them describe the technical developments in their fields.

The study of electrical phenomena, aside from its bearings on the material wants of man, affords a wonderful opportunity for masterly reasoning in applying the mind to intangibles. No other branch of science calls for keener or more intensive inductive and deductive reasoning, and no other branch so directly applies theory to practice. Notable work has been done in electrical science, but even today, as manifested in the paper by Dr. Carl Hering and the resultant discussion, there is far from general agreement as to the physical nature of electricity or magnetism. In spite of this fact, engineers and scientists have developed mathematical relations and stated fundamental laws which serve to give quantitative solutions to nearly every problem associated with the application of electricity. These accomplishments prove that the electrical engineer has a mind which recognizes and appreciates the reasoning and experimentation of specialists in the various fields, and the large attendance at the convention and close attention given the speakers give added weight to the assertion.

A feature of the convention this year was the many papers on communication. Radio and wire telephony have established new records, and the large audiences that heard the papers recounting these achievements proved that communication is no longer of interest only to a small group of specialists. The vacuum tube also showed still wider fields of application, these being brought out by the paper on the crest voltmeter and the lecture on the pallophotophone.

It was fitting that the first joint session of two bodies of engineers separated by nine hundred miles should have taken place at this convention. Chicago and New York electrical engineers discussed their problems together by the aid of telephone lines and "loud speakers," while many thousands of others, if they so desired, could also hear the program through the agency of a broadcasting station and home radio receiving sets. A new advance in the art of communication has been made, and its results on national social progress cannot be gaged. The next presidential campaign may find political leaders addressing 70 per cent of the people at one time by word of mouth and from one location, and perhaps members of this audience may question such speakers directly, independently of distance.

Metering has become a very complicated and rather

unsatisfactory field for engineers, but the papers at the convention brought out the fact that researches are under way which give promise of a simplification in mechanism and greater accuracy in measurements. Metering is a difficult field for engineers to obtain results in because it is so largely controlled by rate making—the engineers must produce meters to operate under complicated rate systems. It seems almost impossible—or at best very expensive—to construct any mechanism to take into account alike demand, off-peak conditions, kva., condition of balance, power factor and time. Much thought will be required to gain a correct solution of the problem.

In the realm of electrophysics the convention had some notable research contributions, and a great deal of interest, together with some amusement, was occasioned by the discussion between the disciples of Maxwell and their opponents. Controversial opinions may serve to bring out new quantitative facts which will advance the art.

In the matter of social features and visits and excursions to points of interest New York showed its many advantages for a winter convention. The large attendance attested the popularity of the location. On the whole, the midwinter convention just closed was the best ever held by the Institute.

### Transformers of Low Core Loss an Embarrassment

THERE has been a great deal of talk about the development of special low-core-loss transformers for use in rural electric service. Some tests made recently at the Iowa State College by Prof. Frank D. Paine indicate that transformers designed for low core loss introduce not only a low-power-factor problem that is undesirable from a system viewpoint but also a metering problem if master meters are used on such lines. The tests were made on a line operating at 2,300 volts and 25 cycles. Fifteen per cent of the energy shown by the master meter could not be accounted for. On a 1-kw. transformer tested the loss was found to be 16.5 watts, but the exciting current was 1.7 amp. on the low-voltage side, or nearly 20 per cent of the full-load current. The exciting current for the entire line was 3.2 amp. on the 2,300-volt side, and the full-load current during maximum demand was 6 amp. The power factor on the line during the day ran as low as 7 per cent. For about twenty out of twenty-four hours the power factor of the line was very low. The net result was the throwing of a large error on the master-meter readings.

The situation revealed in this case is an indication of the care needed in considering modifications of existing apparatus to meet new conditions. On the face of the proposal a transformer of low core loss seems reasonable for present rural electric service requirements and it has had some enthusiastic support. If it introduces other complications like those indicated, it may not be worth while to spend time and energy on the design of a new line which will also complicate the present transformer situation by adding another transformer to those already called standard. Both the manufacturers and the users have spent much time and energy in reducing distribution transformers to a basis that will keep the manufacturing situation within reasonable bounds. There should be a sound basis for the addition of any new types to the present list.

### How a City Gains by Better Street Lighting

ONE OF the certain benefits of better engineering is profit to all who are concerned. However pecuniary benefits may be divided, everybody wins in improved and more reliable service and in the consciousness of bettered conditions. An analysis, for example, of the effect of the improved street-lighting methods in Kansas City described in the Feb. 10 issue of the ELECTRICAL WORLD will bear out this statement. First of all, the city wins heavily in quantity and quality of lighting, especially when one reduces the situation to cost per candlepower-hour or its equivalent. This is encouraging of itself, but to it are added certain intangible assets which do not appear on any assessor's books but which must not be forgotten in the audit. A very large amount of service has been put underground, which not only greatly lessens the chance of the system being crippled by storm, but makes for a better-looking city, with a general increase of values. Not even the most hardened electrical man likes the appearance of overhead wires. They are an economic necessity in sparsely settled districts, where it is that or nothing. Abroad, under similar conditions, it is generally nothing, or its nearest approximation, paraffin. But when, as here, a decently economical underground system has been laid out overhead wires must go, with a chorus of "Good riddance!" In this case the distribution system adopted, with the constant-current transformers out of doors on the poles, makes it possible, too, to dispense with a large amount of what would otherwise be dead wire.

Aside from this gain in appearance, there is the effect in maintaining public order, which, as a result of experience, has been shown to be very important. In these days, when crimes of violence run rampant, the old adage that an arc light is as good as a policeman takes on a new significance. One rarely hears of a hold-up in the full glare of a street lamp—daylight crimes are familiar, but it is an unusual brand of thug who picks out a victim in the most conspicuous place on the street.

Good service at reasonable cost means plentiful lighting, and there are few better investments within reach of the community. And, as these recent schedules show, the investment is by no means heavy compared with the benefits conferred. In addition, in the Kansas City case, there is full provision for the taking over of the system by the city on a definitely stated basis. But, in point of fact, there is no reason to believe for a moment that the citizens want to take a chance on municipal ownership even on the very reasonable terms made possible. The contract leaves little room for dispute even in the often troublesome matter of depreciation, and, starting from the beginning of a new development, the original cost and the costs of additions are determinable.

What does the operating company gain? A better and more economically operated distribution system; a contract which, if disturbed at all, is affected only in ways known from the start, and, more than all, the confidence of the citizens that they are getting fair play and an honest accounting. Not one voter in twenty can form a clear idea of the merits of an old and often changed agreement. Here the voter can start fresh and see plainly that he is getting full value for his taxes. The sentiment of mutual fair dealing is the best security for the city and the best assurance of prosperity for

any operating company. It is feasible and profitable thus to play with the cards on the table, the only real stake being an open rivalry for the betterment of the city and prosperity of its industries, equally important in the long run for citizens and utility companies alike.

## Money Spent for a Good Cause

THE past week has witnessed scare heads in the daily press over the reports of and comments on legislative investigations in regard to expenditures by utilities necessitated in fighting vicious legislation. Particularly has this been true in California, where a special committee of the State Senate has been holding open sessions in San Francisco looking into the expenditure of money to defeat the proposed water and power act at the election last November. Virtually all of the prominent electric light and power men in that state have been called to testify before this committee, and it is a source of great gratification that they met the summons with complete frankness, although it was generally considered that they were not legally bound to appear.

Not only are they to be congratulated upon the frank presentation of the facts which they made, but also upon the firm stand they took in the matter of the use of their own money in proper ways to fight vicious legislation whenever it is threatened. This right they steadfastly insisted upon in view of the fact that the securities of more than a hundred thousand citizens of California are put in jeopardy by such attempts. Self-preservation has ever been recognized as the first law of nature, and in all things that make for or against the continued prosperity and usefulness of the electrical industry there is no exception to this law.

## Loop Distributing Circuits of Higher Voltage Needed in Some Places

THERE are some indications that the limit to the amount of power that can be distributed in a given city area from low-voltage street circuits is being reached. With greater and greater concentration of load in big buildings the problem of finding street room for either overhead or underground circuits is bound to become increasingly acute. In the past many companies have in congested districts followed the policy of leasing substation sites. Sometimes these have been basements of buildings so located that considerable areas could be served, and sometimes they were tracts of land on which structures were erected. But it is now not infrequently found difficult or impossible to lease building space, and where it can be leased the term of years is such that expenditures for substation equipment of any large capacity and provision for growth are economically impossible. The purchase price of land in such areas is on a basis that prohibits the acquirement of a large number of sites. As a matter of economic necessity it appears that a way must be found to decrease the number of circuits used for street distribution systems, the number of substation sites and the amount of substation apparatus, if any extensive development in the direction of load concentration in city areas is to take place in the future.

In one rather prominent case where a low-voltage direct-current substation layout is being revised the plans adopted were not carried into effect before new building projects in the area served created a problem that was solved only by taking the new building service from high-voltage alternating-current circuits that happened, for other reasons, to form a loop around the district. The lighting and general power service is in this case given through ordinary step-down service transformers, and the elevator service is provided with direct current through motor-generator sets. The direct-current substation rearrangement is being carried out in the district referred to because it will take years to eliminate the low-voltage distribution system, yet the plan and means for eventually supplying the whole service from high-voltage alternating-current circuits is provided and the low-voltage service will eventually be eliminated.

In another case the lack of room for overhead circuits is forcing the substitution of 13,200-volt circuits to serve industrial load that has hitherto been served at 2,300 volts. Similar instances could be cited in great number. The point is that radical changes in the method of approach to the problem of distribution in congested areas face the engineer. Nor will it pay to consider only the present problem; plans for such areas must be made with adequate consideration of probable development well into the future.

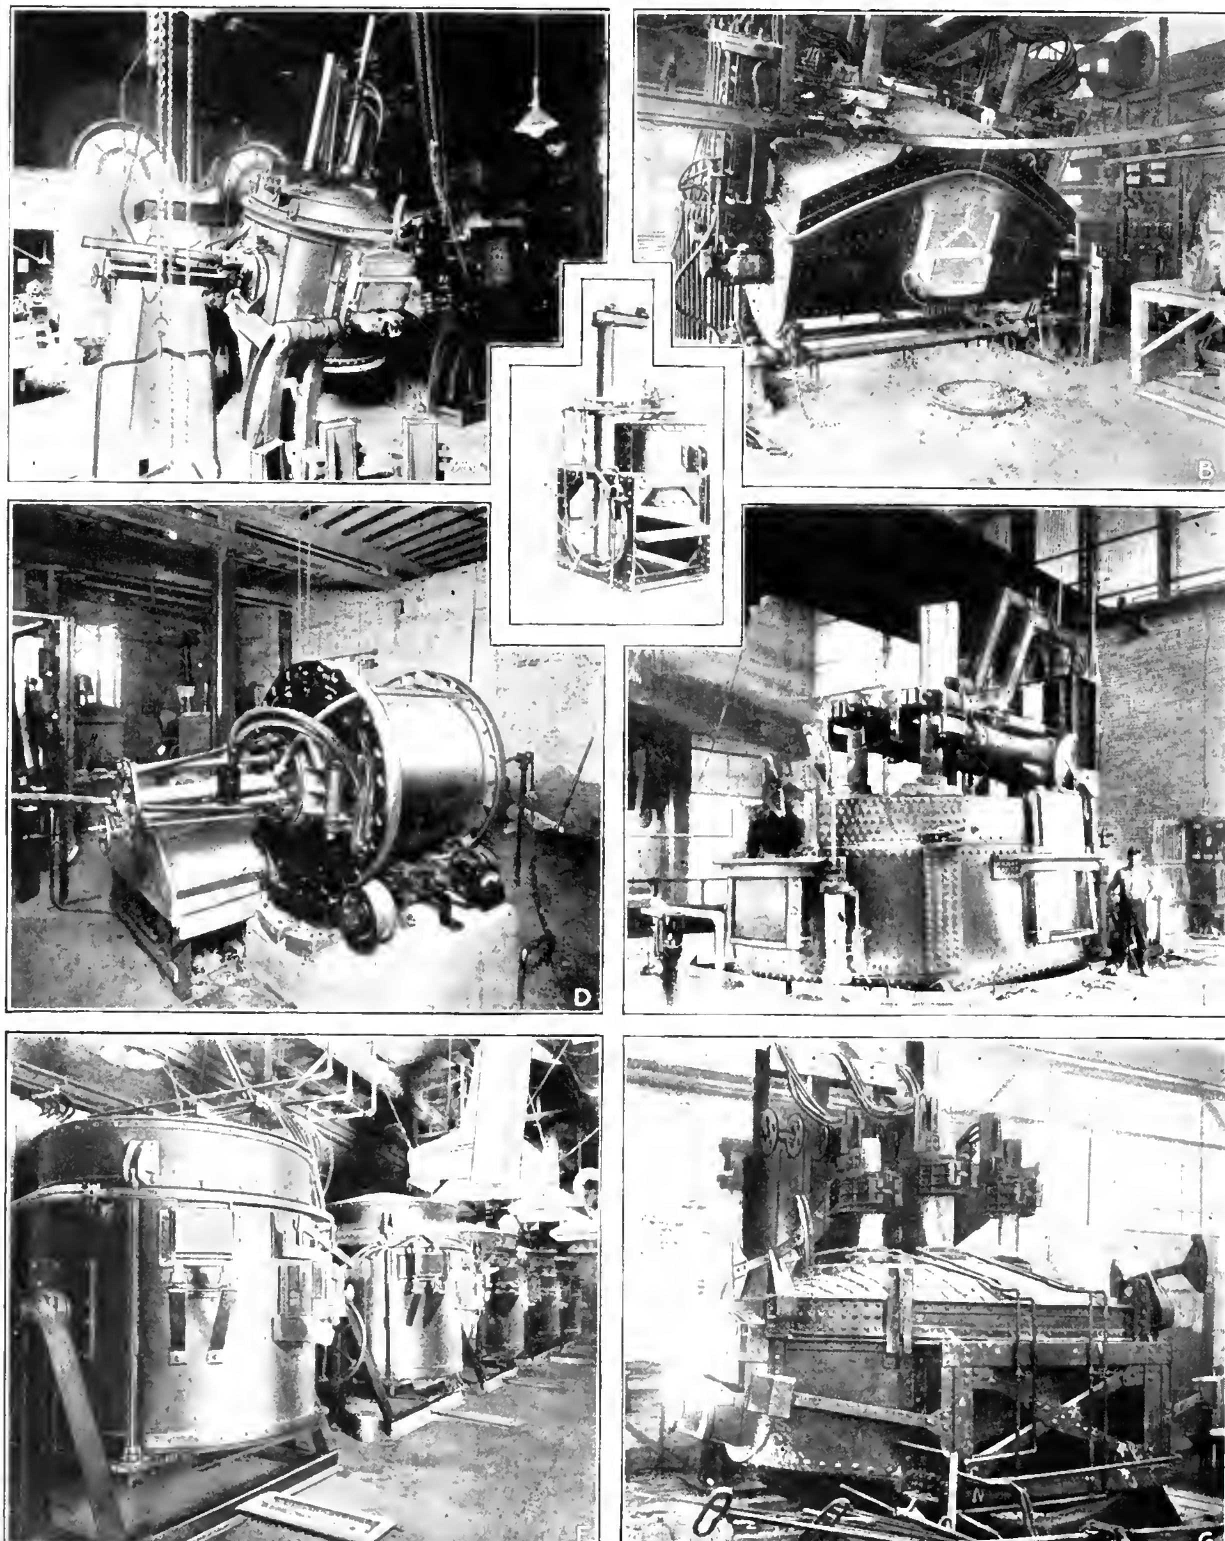
## Some Outstanding Problems of Line Insulation

JUST at present the insulation of lines for the extra-high voltages now coming along seems to develop slowly. We need higher mechanical qualities and higher dielectric strength if the future's demands are to be met. In particular we need to make more skillful use of the best materials that are available. The shielding or grading of strings of insulator disks so that the burden will be equalized is perhaps the most important step that can be taken immediately. Its usefulness has been well demonstrated, but full advantage of it has seldom been taken. It has been called "theoretical," or some similar attribute favored by the conservative as most derogatory to radicalism has been ascribed to it, although, on the other hand, it ought to be self-evident that it is unwise to load the entire burden of supervoltage on one or two elements of the string.

Apart from this feature of suspension design or disk arrangement, there should soon be advances in the strength and specific insulating qualities of the individual disks. Perhaps the most radical line of advance is toward the use of pure fused silica-quartz glass, instead of ordinary glass or even porcelain. Fused silica has, if homogeneous, very high insulation and mechanical strength, and on account of its low expansion it is remarkably free from annealing strains. Just what its best economic use may be remains to be seen —whether shorter strings should be used, or smaller disks, or composite strings with the silica bearing the heavy duty. Meanwhile there are promises of denser and more reliable porcelain which will presently play its part.

The one thing certain is that with the coming of supervoltage systems—and their tread is rather cautious —there will be need for every precaution against failure to deliver the goods, so that line building and insulation take on new importance. In such work question may well arise as to whether the several phases should not be carried on separate steel-pole lines instead of the ordinary system of towers carrying double circuits. The object to be sought is the utmost possible immunity from interruptions of service, quite irrespective of precedents, which are too often mere enemies of progress.

# Electric Furnaces Produce Quality Products



THE drastic specifications for materials, the elimination of waste in their production and the reduction in available labor for operation have given new impetus to the application of electric furnaces in melting and treating brass and steel.

Various types of furnaces are available and a great development and improvement has occurred in the control and regulating equipment so that the furnace now affords a splendid load for central stations. The photographs show several types of brass and steel furnaces. A is a Rennerfelt furnace for brass melting. B is a contact arc resistance furnace also used for brass melting, while C is a Repel-Arc type. D is a Booth rotating-type brass furnace. The Heroult furnace, E, and the Vom Baur furnace, G, are used in steel making, while F is a Bailey resistance furnace.

# Eleventh Midwinter Convention of the A. I. E. E.

### Large Attendance and Sustained Interest Mark the 1923 February Gathering—Papers Presented Recount Technical Advance Along Various Lines

THE eleventh midwinter convention of the American Institute of Electrical Engineers was, judging from the attendance and the spirit evinced in the meetings, one of the most successful ever held. The official registration was nearly 1,150, and many more attended the meetings, the smoker and the annual dinner-dance.

Altogether, six technical sessions were held, one Wednesday afternoon, two (parallel sessions) Thursday morning, one Thursday afternoon and one each on Friday morning and afternoon. A joint two-city, radio-broadcasted meeting was held Wednesday evening, as reported in these columns last week. A well-attended smoker was given Thursday evening, with the New York Section members as hosts. In addition to the entertainment features on this occasion C. A. Hoxie of the General Electric Company described and demonstrated the "pallophotophone," an arrangement for oscillographic record of speech, music or other sound to be transmitted later electrically by light-sensitive cells to various loud-speaking devices, radio transmitters or other instruments. The application of this pallophotophone to motion picture films was pointed out, the result being the "talking movie." The great advantage of the pallophotophone is the purity of record and voice reproduction, none of the inherent characteristics of microphones or wax records and other mechanical contrivances being involved. The pallophotophone works on the principle of recording on a moving film light beams from an extremely small mirror, mounted to follow the motions of a diaphragm on which the sound falls. This film is later passed in front of another light beam so as to affect the light falling on a "light-sensitive" cell, which in turn varies the current to correspond with the original voice waves. Audion tubes and other already familiar devices do the rest.

The dinner-dance on Friday night, which closed the convention, was the best attended in the history of this annual function, there being nearly six hundred guests.

In the following pages an extended report of the meetings is given, including abstracts of papers presented (most of which have already appeared, or will appear very soon in the Institute's *Journal*) and the discussions thereon.

## Wednesday's Session Devoted to Progress in Transmission and Distribution

The report of the cable research committee, which constituted the major part of the report of the transmission and distribution committee (E. B. Meyer chairman), was presented by D. W. Roper. He referred to the marked reduction in dielectric loss in cables, improvement in dielectric strength, reduction in thickness and increase of insulation resistance. It is now possible to get lead-covered cable with impregnated paper insulation and with a dielectric loss so low that the limiting temperature is that which will cause permanent deterioration of the insulation. To operate underground cables at the temperature specified by the A. I. E. E. rules, it would be necessary to operate them at such a very low current density that it would be uneconomical. Higher current densities would require operating the cables at temperatures considerably higher than those permitted by the Institute rules. However, this is being done already without signs of deterioration.

In the past there has apparently been considerable confusion between troubles caused by dielectric losses and troubles caused by dielectric stresses. Cable failures due to dielectric stresses are quite rare. Engineers are not in accord as to the maximum permissible dielectric stress nor as to which dielectric stress is the limiting feature in high-tension cable design and operation. They can, however, be guided by the stresses that exist in cables that have been in successful operation for a number of years.

From a comparison of insulation thicknesses on American and foreign cables it may be noted that the ordinary English practice is appreciably below the minimum recommended by any American manufacturer, and also that the recent thickness adopted by one English company for a 20,000-volt cable is 25 per cent below the previous practice and about 30 per cent below ordinary American practice. In Italy the high-voltage cables apparently have about the same thickness of insulation as is used in this country.

According to the best information obtainable, the English operating companies carry about the same load on various sizes of three-conductor cables as is customary in this country, but because of the improved facilities for radiating heat the maximum operating temperature of copper is about 50 deg. C. If cable bells are not to be the weak feature, they should be able to withstand as high overpotential stressing as the cable. If it is impossible to go materially above 200 kv. in a three-conductor cable bell, then a limit may be placed on three-conductor cables at about 40 kv.

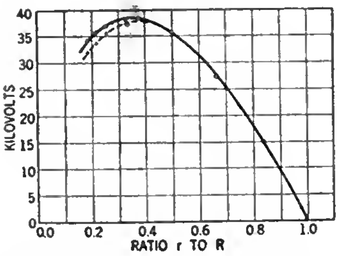
Leading American manufacturers have gradually changed from vegetable oil impregnating compounds to those with mineral-oil bases, and practically all are now using the vacuum process of drying and impregnating. One foreign manufacturer is using a thin transformer oil, but the lowest losses reported with its use are not materially below the minimum losses which have been reported by one American manufacturer using a mineral-base compound.

According to tests, it appears that if the impregnated paper insulation will withstand, say, a thousand double folds in an endurance test, then the cable will pass the bending test without difficulty.

Owing to the fact that the sheath current in single-

conductor cables may reduce the carrying capacity of the cables 10 or 15 per cent, the losses in the current in the sheath must be taken into consideration in calculating the efficiency of transmission.

Referring to the maximum voltages at which underground cables are being operated in foreign countries, Mr. Roper pointed out that while a number of them are rated at very high voltages, most of them are operating below rating. At least one of the cables, however, is operating at 33,000 volts, one three-conductor cable of this rating having been in operation since 1914. A single-conductor cable at Barcelona, Spain, has been in operation at 50,000 volts since 1914 without any cable failures except one caused by electrolysis. The highest-voltage cable in this country is a 30-mile section operating at 33,000 volts in Chicago. No failures have occurred since it was installed, but it has not been operated at the limiting voltage. Some new cable will be installed there shortly which will be operated at 44,000 volts, to serve as a station tie line permitting two-way exchange. The high-voltage joints will require 3-ft. to 4-ft. sleeves, necessitating special manholes.



RELATION BETWEEN RUPTURING VOLTAGE AND THE RATIO OF THE CONDUCTOR RADIUS TO THAT OF THE DIELECTRIC

The transmission and distribution committee report read by E. B. Meyer stated that the outstanding features of present overhead construction are the continued tendency toward higher voltages both in transmission and distribution and the improvements in construction methods as a result of standardization in the materials and design. In a general way it can be said that the manufacturers have made good their claims of several years past that insulators of the latest manufacture are not subject to the rapid depreciation which was the cause of such concern a few years ago. Engineers who have given the insulator much study believe that the insulator unit for 220 kv. should be larger so that the number of units may be reduced to about the same number as now is used for 100 kv.

It is interesting to note that the Southern California Company already has 27 miles of one of the Big Creek lines in operation at 280 kv. and 240 kv. for experimental purposes. Increased loads and areas covered have finally made evident the inadequacy of the customary 2,300-volt and 4,000-volt circuits for many distribution problems, with the result that 6,600, 11,000 and 13,200 volts and higher voltages are now entirely standard in many districts for purely distribution purposes.

With a relatively steady increase in density of Edison loads, it has been found desirable to increase the size of the meters and conductors to as large a figure as may be installed safely or as the existing ducts will admit. A very decided point in favor of cables containing pressure wires is that they permit the adoption of junction-box or terminal circuit breakers for automatic isolation of faults.

Considerable divergence of opinion exists regarding the type and size of cables to use in Edison mains, the location of boxes and the fusing of meters and mains. The use of direct potential rather than alternating potential for high-voltage stress with installed cables is being investigated by operating companies. Even where sufficient power is required to reduce the faults or failures so that the trouble can be located, the cost of the apparatus is said to be only about one-quarter of the cost of alternating-current testing equipment. Foreign investigations indicate that the ratio of direct current volts to alternating-current volts to produce the same test results should be two and a half to one, but American manufacturers up to the present time have not been willing to agree on a ratio higher than one and a half.

Foreign practice in transmission and distribution was also outlined.

### Apparent Dielectric Strength of Cables

Although a great many investigators do not believe in free ions in solids, said Robert J. Wiseman, it is remarkable how well computed results agree with experimental data, if it be assumed that they do exist and that the laws of ionization can be applied. The ionization theory has been applied by the author satisfactorily to all data made available so far. According to these comparisons, the author contends that the law $V = K_0 [1 + (a/\sqrt{r})]\sqrt{R}\, r \log R/r$ is applicable to all ratios of conductor radius to insulation radius.

Since there is no independent evidence of the free mobility of ions in solid dielectrics, Dr. J. B. Whitehead urged hesitation in explaining cable failure in terms of ionization theory. Despite the fact that the law has been found for breakdown of gases and a theory has been developed, no one is in a position to say exactly what takes place in the gas under these conditions. Therefore, with the inconsistent results obtained in cable research, one should be still more cautious in assumptions.

Mr. Davis maintained that greater variation in results was obtained by Wiseman's method than by Middleton's method, citing 60 per cent maximum variation for results with Wiseman's method and 19 per cent with Middleton's. Mr. Wiseman agreed that engineers should go slow in applying the theory of ionization to cables, but contended nevertheless that there is some agreement with this theory in cable breakdowns.

### Short-Circuit Currents in Power Networks

The merits and limitations of the short-circuit calculating table were discussed by O. R. Schurig, who considered its proper field of application, its accuracy and the methods of using it. Its chief field of application, said the speaker, is in making polyphase short-circuit current calculations required for the selection of oil circuit breakers, in the determination of relay settings and in the layout of distribution systems. It is not generally applicable to phase-to-phase short circuits or to phase-to-ground short circuits, on account of the unbalanced current division among the phases. These problems must be solved by calculation or by alternating-current tests.

The errors of the short-circuit calculating table are due to the neglect of capacity-charging currents and to dissimilar impendance angles occurring in the various elements of a network. The former is almost always negligible for polyphase short circuits, being smaller than 10 per cent for a three-phase short circuit occurring in an aërial line 200 miles from the generator.

In a great many systems the resistance component of all the impedance may be entirely neglected for short-circuit determination. This method, the reactance

method, generally gives erroneously high current values. The errors are safely below 20 per cent, and commonly under 10 per cent, under the following conditions:

(A) In systems in which circuit elements of dissimilar impedance angles occur in series connection only (*i.e.*, parallel-connected circuit elements having impedance angles less than 15 deg. apart), provided the circuit constants are within a definite range of the following character:

(1) Generating-station reactance not lower than distribution-system impedance and angle of the latter not lower than 30 deg.

(2) Generating-station reactance not lower than one-half the distribution-system impedance and angle of the latter not less than 45 deg.

(3) Generating-station reactance not lower than one-fifth of distribution-system impedance and angle of the latter not less than 55 deg.

(B) In systems not covered by (A), provided that all impedance angles are larger than 55 deg.

For systems not covered by the range of circuit conditions defined above, but having impedance angles not materially below 30 deg., the impedance method is preferable and gives errors well below 20 per cent and commonly below 10 per cent. The short-circuit current values are generally low. Cable systems with current-limiting reactors in some of the lines come within this class. While the impedance method is particularly suited to systems having parallel-connected circuit elements of widely dissimilar impedance angles within the limits stated, it is not a substitute for the reactance method in systems of type (A) and (B).

R. A. Doherty called attention to three major sources of error in using calculating tables for short-circuit calculation, namely, the generator reactance, the calculation tables and the use of decrement curves. He referred to the tables as a means of determining the most desirable distribution system and behavior of generators under transient conditions.

G. M. Armbrust referred to a new alternating-current calculating table developed in Chicago which is intended to enable study where large impedance angles are involved but is not intended to replace direct-current board.

### Qualitative Analysis of Transmission Lines Not Sufficiently Accurate

Basing his discussion upon a previous presentation by Percy H. Thomas, H. Goodwin, Jr., introduced the "critical load" as a means of qualitatively analyzing transmission lines and gave a simple formula for determining this load and the effect of variations of power factor, voltages, etc. The effect of various line constants upon the critical load were briefly discussed. Working from the critical load, a vector interpretation of the action of a long high-voltage transmission line was given. From this vector interpretation it is possible to predict certain essential operating characteristics of transmission lines. To show the applications, two practical examples were selected and solved.

Some of the properties of the critical load which are useful in analysis of transmission lines of present commercial lengths are as follows, the speaker said:

(1) The critical load when placed on a transmission line at unity power factor will be transmitted at unity power factor. The current will be constant throughout the line. The voltage drop will be the same as for direct current ($IR$). The power loss will be equal to the direct-current power loss ($I^2R$).

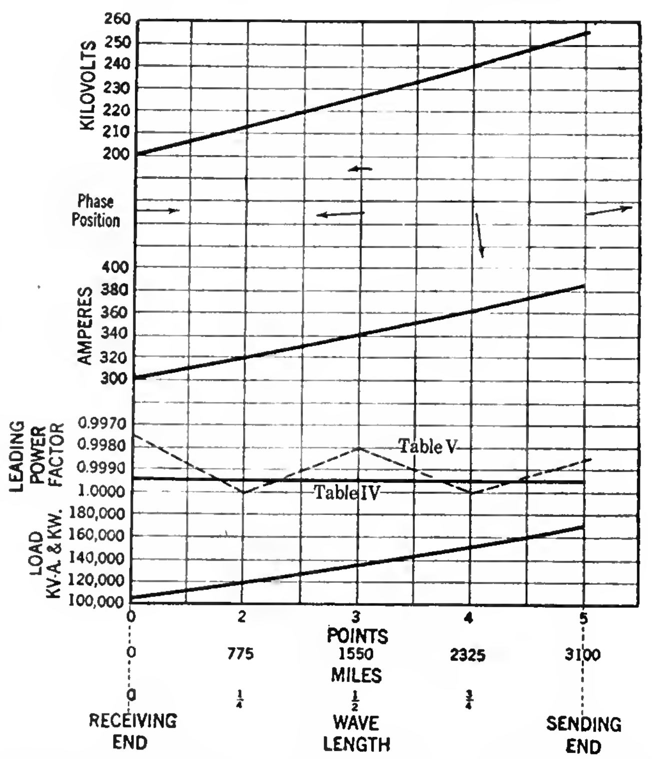
(2) If the kva. load is greater than the critical load, the power factor at the sending end of the line will always be more lagging than the power factor at the receiving end of the line.

(3) If the kva. load is less, the power factor will always be more leading than that at the receiving end of the line.

(4) If the load is the critical kva. but at a leading power factor, the power factor at the sending end of the line will be still leading but nearer unity.

(5) If the load is the critical kva. but at a lagging power factor, the power factor at the sending end will still be lagging but nearer unity.

From the formula for critical load, which is kva. $= 1{,}000\ E^2/\sqrt{L/C}$, it is evident that an increase in the



OPERATING CHARACTERISTICS OF A VERY LONG TRANSMISSION LINE SHOWING HOW THE POWER FACTOR VARIES WITH DISTANCE

capacitance of the transmission line will increase the critical load, whereas an increase in the reactance will decrease it. For lines of very high voltage the full loads will correspond quite closely to the critical loads, but light-load conditions often present greater problems than full load.

All of the discussion on Mr. Goodwin's paper was in the nature of requesting qualification of statements and proof of assumptions. R. D. Evans differed with the author regarding the conditions for most efficient transmission and stable operation, saying that conditions would be better at slightly lagging power factor rather than at 100 per cent power factor. Professor Karapetoff maintained that Mr. Goodwin should qualify his statements and prepare an appendix to accompany the paper proving the assumptions made. He pointed out that the critical load is dependent on the line constant as well as on voltage and current. Furthermore, the current is not the same at all points on the line and may be simultaneously lagging or leading, depending on the point at which it is observed. Dr. Steinmetz contended that the entire reasoning in Mr. Goodwin's paper is approximate, because it is based on the assumption that the surge impedance is equal to the square root of $L$ divided by $C$ instead of the square root of $X$ divided by $Y$.

Mr. Goodwin replied to these remarks by saying that for commercial lines the surge impedance differed only

a fraction of a per cent from the square root of $L$ divided by $C$ and that the rules for calculating the critical load apply only to commercial lines. He pointed out that the purpose of the paper was to determine electrical characteristics of the line and not the economics of the situation, which must depend upon Kelvin's law. The paper was intended only to show what loads can be placed on lines to give stable operation. At the critical load no synchronous condensers are needed on the system. If greater or less load is carried, then condensers or reactors will be required for loading the system. However, unless long high-voltage lines are operated at 100 per cent load factor they are not feasible, he contended.

### Kinematic Device for Calculating Long Transmission Lines

An ingenious kinematic computing device was displayed and described by Prof. V. Karapetoff which can be quickly set to represent vectorially the voltage and current of any point of a long transmission line with uniformly distributed constants and a given load. Its operation is based on the fact that the current or voltage at any point in a long transmission line may be represented by two vectors rotating in opposite directions and varying in length according to the fundamental differential equations of a line. The parts of the device are made to assume at will different positions corresponding to different points on the line. The constants of a line to be represented are adjustable and a complete set of performance curves can be obtained. Conversely, by a few simple trials, the best constants of a line and the necessary kva. of a synchronous condenser may be found to give the required performance characteristics. The current, the voltage and the power factor can be read directly from the device for any desired point of the line.

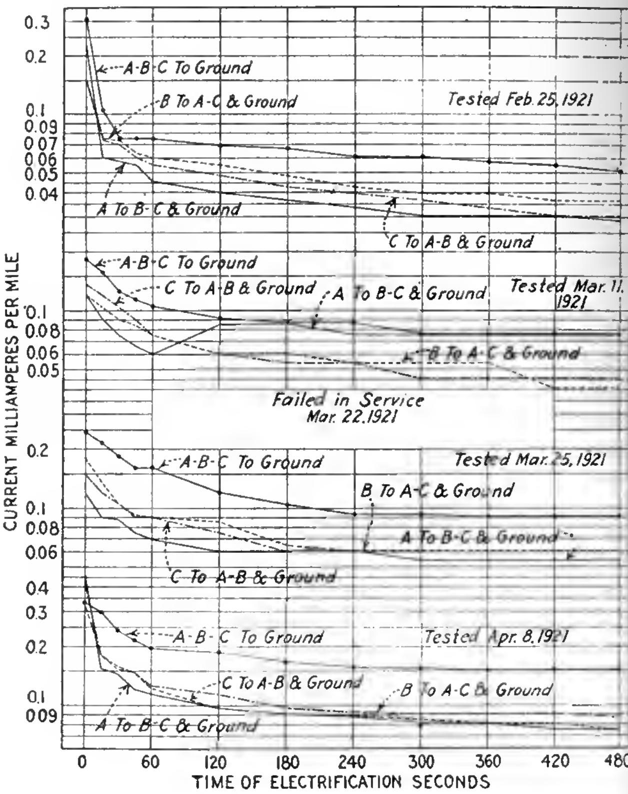
Two practical examples were calculated by this device and by means of hyperbolic functions of a complex variable, with very close agreement.

### Routine Testing for Impending Cable Deterioration

In an effort to develop a routine test which will serve to detect an impending fault in underground cables, the Philadelphia Electric Company has made use of the kenetron as the source of high-potential direct current. By means of it, declared Howard S. Phelps and E. Dean Tanzer, a large volume of data has been secured concerning the input current for a cable as a function of the time after complete electrification at a constant high potential. These data when plotted as curves show by their shape the condition of the cable insulation.

Curves showing a sharp decrease in the magnitude of input current during the first minute and a gradual but persistent rate of decay for the succeeding six or seven minutes indicate that the insulation is in an acceptable condition from the operating point of view. However, if the curves show little if any decrease or a persistent tendency to increase during the time interval of the test, it is an indication that the insulation has deteriorated to such a point that the cable may be expected to fail at an early date if retained in service. The degree of deterioration is indicated, first by the time which has elapsed in complete electrification before the increase occurs and, second, by the sharpness of the upward trend of the curve in any instance.

The value of this method of testing has been demonstrated by its actually having detected a considerable number of impending cable faults before they became a menace in operation. Additional refinements in the methods of measuring the input current for different classes of cables may be desirable. Further investigations are being carried on to determine the necessity.



PHASE "A" HAS AN INCREASED CURRENT AND CABLE FAILED IN ELEVEN DAYS. WHEN REPAIRED AND RESTORED TO SERVICE THE CURRENT SHOWED CHARACTERISTICS SIMILAR TO THOSE OF FEB. 25

Investigations of certain theoretical features are also being conducted, among them being oscillographic studies of the input current and voltage under test conditions.

Considerable interest was shown in the routine method of detecting impending cable faults as presented by Messrs. Phelps and Tanzer. J. L. Hayden pointed out that the method is particularly advantageous because it permits detecting gradual deterioration of the cable without subjecting it to extreme high-voltage tests and besides affords an opportunity for studying the internal action of the dielectric. However, he pointed out that the alternating-current tests have the advantage that they also indicate the dielectric loss.

D. W. Roper declared that this method has been applied in Chicago to the study of high-efficiency underground cable with low dielectric loss, but the studies have not been conducted long enough to reach any definite conclusions as yet. He brought out the interesting point that the initial current was about 150 times the final input current, indicating the need of more sensitive current measurement after the first few minutes if any upward trends in the curve are to be detected.

To show the reason for the change in the flow of current transient observed by this routine method of testing, Dr. C. P. Steinmetz gave a very interesting explanation of the phenomena which occurred in the dielectric. This explanation sustained Maxwell's theory

of dielectric absorption. In the perfect dielectric there is no slow transient, Dr. Steinmetz pointed out. In a non-homogeneous dielectric, however, the voltage gradient is distributed first inversely proportional to the specific capacities of the built-up insulation. Since the current is proportional to the voltage gradient, the dielectric resistivity and specific capacity, the current capacity cannot be the same in the different dielectrics unless the resistivities bear the same relation to the specific capacities in each dielectric. Hence the current must flow and establish charges which redistribute the voltage gradient. The speaker said that this method should therefore enable the investigation of components of dielectrics.

Regarding the difference between initial and final input current brought out by this test method, Mr. Tanzer said, in closing the discussion, that it may be necessary to have more refined methods of reading current on the more modern cables. He asserted that the inversion of the curve is the important factor, and not the difference between the initial and final currents. With refinements it may be possible to adapt this method to the testing of armature coils.

## Joint Session with Chicago on Wednesday Evening

The technical aspect of the loud-speaking telephone and the problem involved in attaching the loud speaker to long-distance telephone circuits were discussed in a joint session with Chicago Wednesday evening by means of two-way long-distance telephony with the aid of loud-speaking instruments. All the papers and discussions were broadcasted. In the first paper, by I. W. Green of the American Telephone & Telegraph Company and J. P. Maxfield of the Western Electric Company, Mr. Green presented the problem encountered in the development of electrical systems for amplifying the voices of public speakers and music and described the equipment as brought to a commercial state and now in use in the United States and various other countries. The system employs four units—a "pick-up" mechanism or transmitter unit, a preliminary amplifier, commonly called the speech input equipment, a second or power amplifier, and a receiver-projector unit for transforming the amplifier current back into sound and properly distributing it throughout the space to be covered.

In the second paper, by W. H. Martin and A. B. Clark, both of the department of development and research of the American Telephone & Telegraph Company, Mr. Martin, speaking at Chicago, presented the various applications of the public-address system with telephone lines, stating the requirements for the lines, the circuit arrangement used and the more important operating features. He also gave a detailed description of the system used on Armistice Day, 1921, when large audiences at Arlington, New York and San Francisco joined in the ceremonies attending the burial of the unknown soldier at the National Cemetery at Arlington, Va. The main requirements for using loud-speaking equipment on this type of work are that the apparatus shall transmit a sufficiently broad frequency range and that short pulses within this range be transmitted without introducing oscillations of their own. This is best accomplished by using non-loaded open-wire lines or extra-light-loaded cable circuits.

Both papers were discussed simultaneously before the Chicago and New York audiences by J. J. Carty, vice-president of the American Telephone & Telegraph Company; B. E. Sunny, chairman of the board of directors of the Illinois Bell Telephone Company, and E. B. Craft, chief engineer of the Western Electric Company. Mr. Craft pointed out that telephone development was one of the master elements in research and in the progress of humanity—an opinion strongly indorsed by Mr. Carty. Mr. Sunny, in Chicago, said that the A. I. E. E. is now reaping the benefits derived from the movements which it has so amply backed and spoke of the Edison medal as a help to development and effort.

### Observations on Electric Railway Practice in Europe

European practice regarding the type and character of rolling stock as compared with that used in America, the use of electric drive or locomotive, and the voltage used in the electrification of lines, was ably discussed by W. B. Potter of the General Electric Company, who has recently returned from an extensive trip in Europe. An interesting feature of European locomotives, he said, is the efficient condition in which they are kept. This is because the engineer operating the locomotive considers it as almost his personal property.

The compilation given here affords an idea of the extent of railway electrification throughout the world.

STEAM RAILWAY ELECTRIFICATION THROUGHOUT THE WORLD

| | Ronte, Miles | Number of Electric Locomotives | | Route, Miles | Number of Electric Locomotives |
|---|---|---|---|---|---|
| United States | 1,607 | 375 | Spain....... | 48 | 17 |
| Switzerland.... | 661 | 156 | Canada....... | 49 | 9 |
| France........ | 602 | 338 | Japan....... | 39 | 42 |
| Italy....... | 650 | 309 | Norway..... | 39 | 37 |
| Germany...... | 550 | 49 | Mexico..... | 30 | 10 |
| Sweden...... | 237 | 44 | Brazil........ | 26 | 16 |
| Cuba...... | 180 | 18 | China...... | 25 | 13 |
| Austria..... | 340 | 42 | Java....... | 25 | 5 |
| Africa..... | 174 | 77 | | | |
| Chile | 154 | 42 | Total....... | 5,565 | 1,611 |
| England....... | 129 | 12 | | | |

This table includes the steam railways which have been electrified or are in prospect of electrification, but not the steam railways on which multiple-unit trains are being operated exclusively or railways which were not formerly operated by steam. The mileage is less than 1 per cent of the railway mileage of the world. To bring about future electrification, Mr. Potter said, many engineering and economic problems must be solved and their solution demands the co-operation of all engaged in the furtherance of railway transportation.

## Telephone Subjects in One Parallel Session on Thursday

Special methods are required to maintain the necessary stability of telephone transmission when small-gage cable circuits are used to handle long-distance service over distances up to and exceeding a thousand miles, according to the paper by A. B. Clark on "Telephone Transmission Over Long Cable Circuits." Several factors involved in the transmission of voice currents over long toll cable circuits must be considered. Among these are "echo" effects, transient impulse and attenuations and corresponding amplifications. To eliminate "echo" effects any unbalance in the system must be very small and the loading of long lines must be made at points further apart than with shorter lines. Changes in attenuation caused by the effects of varying

temperatures on the resistance of the conductors may be regulated by means of automatic regulators placed at every third or fourth repeater station in order to keep the transmission levels within proper limits. The repeater gains are raised and lowered automatically by this regulator, thus overcoming the differences in attenuation caused by the temperature changes.

In discussing this paper, J. J. Pilliod emphasized the point that space must be conserved by using cables for telephone work. Illustrating this, he compared the space requirements for a 300-circuit telephone system. If these lines were placed overhead, it would require 69,000 lb. of copper per mile and ten pole lines. On the other hand, with a cable system only 15,000 lb. of copper per mile would be required, with no pole lines if placed underground and only one if placed on poles. He pointed out that with overhead construction the size of wire must be very much larger than that required for the actual telephonic transmission in order to meet weather conditions such as sleet storms, heavy winds, etc. With the cable systems all these conditions are eliminated.

TRANSIENT IN NO. 19 EXTRA-LIGHT-LOADED LONG DISTANCE TELEPHONE CABLE

### Theory of Electric Wave Filters Built Up of Coupled-Circuit Elements

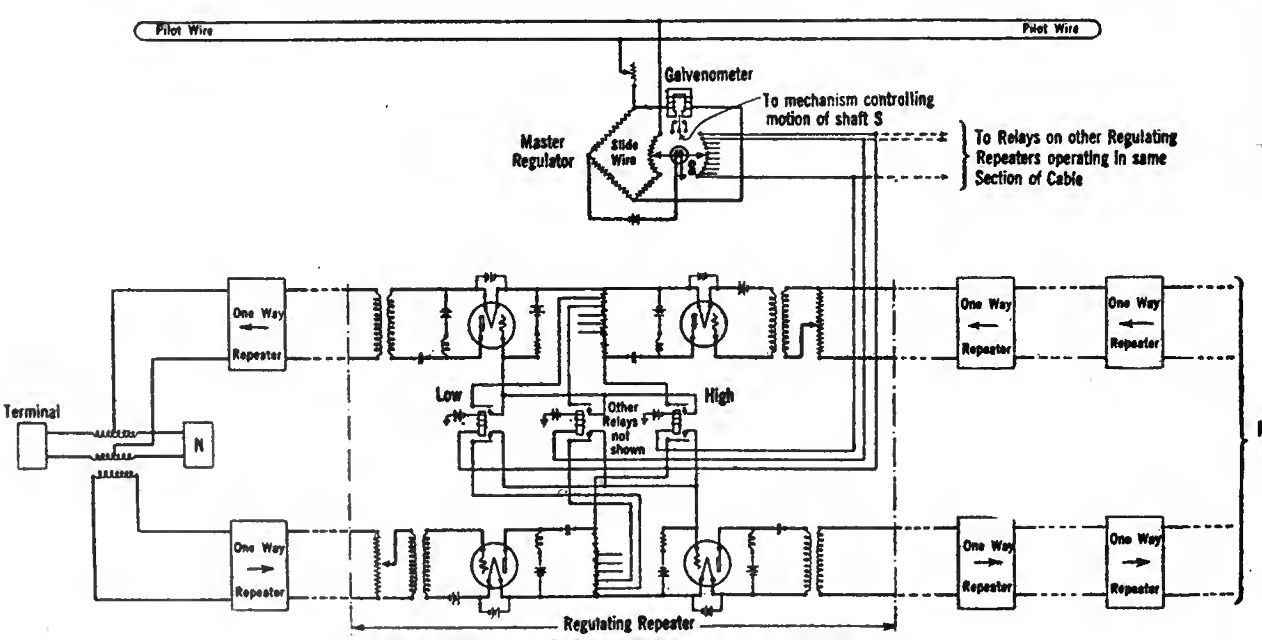
The problem of separating currents having frequencies which lie in a given band from currents of all other frequencies by means of wave filters, with particular reference to telephone circuits, was presented by L. J. Peters, who pointed out some new properties of certain types of systems built up of coupled circuits, showing how systems having preassigned characteristics may be built up in a rational way. Coupled circuit networks or filters are handled in a manner similar to those used in determining the properties of long lines with distributed constants. This method of treatment leads directly to the rational design of an electric system of a type which the older treatment of methods did not assume to exist. By proper termination and design sharp changes in the attenuation frequency characteristic can be employed to build up fiber networks of any type.

### A Diaphragmless Microphone for Radio Broadcasting

A glow discharge microphone dispensing with the diaphragm ordinarily employed with the carbon or condenser type of transmitter was described by Phillips Thomas of the Westinghouse Electric & Manufacturing Company. In this microphone the application of a moderately high direct potential between two electrodes separated a short distance in air, with enough series resistance to prevent formation of the usual type of heavy-current arc, causes the establishment of a low-current, high-voltage discharge having a characteristic glowing appearance. The current consumed is from 1 milliampere to 20 milliamperes at voltages ranging from 200 or 300 to 1,000. Among the advantages claimed are simplicity, durability, low impedance and high sensitivity in addition to elimination of the diaphragm.

A demonstration of the microphone was given, an operator in one of the rooms of the building speaking into the device and also playing various kinds of music. A loud speaker placed in the meeting room reproduced both the speech and music exceptionally well, with almost total absence of distortion. Adjustment of the modulation to correct the imperfections of the existing designs of head telephones and loud speakers may be readily accomplished with this microphone by varying the discharge distance between the electrodes.

Although this new microphone seems to be a very important development, R. J. Jones lamented the lack of information on the load capacity, linearity of response and physical efficiency of the device. The idea that the carbon condenser types of transmitters are un-



PILOT WIRE AUTOMATIC TRANSMISSION REGULATOR

suitable for radio broadcasting and telephone work was thought to be unjustifiable, as recent results vindicated these types, an instance being the very successful use of the carbon transmitter in the joint session of the Chicago A. I. E. E. with the New York session on Wednesday night. Mr. Jones said that there were three radio broadcasting stations using the condenser type, while about thirty were using the carbon type. In all, more than two hundred of the carbon type are in use in both telephone and radio work.

J. B. Taylor deplored the lack of uniformity in the names given to the various radio instruments.

In summing up his paper, Mr. Thomas said that actual operating data would shortly be available on the new microphone.

## A General Session on Railways and Power Equipment Was Also Held Thursday Morning

The second parallel session on Thursday morning was devoted to a series of three papers on railways, two on machinery and one on lightning arresters.

E. J. Blake presented a paper on the automatic train-control problem, indicating that most of the train-control systems are electrical or magnetic in their principle and operation. The Interstate Commerce Commission has commented on the need for some effective check on the functioning of human and therefore fallible engineers and has finally ordered automatic control installation on a large mileage of important lines.

The primary function of automatic control is to stop the train before it enters upon unsafe territory, but the author said that no automatic apparatus should relieve the engineer of complete responsibility for the safe operation of the train. It should act as a continuous check on the proper exercise of that control, intervening to stop the trains automatically only after the engineer has had ample opportunity to act and has failed. The train control device should not increase the hazards of operation in any respect, and the automatic control should place no avoidable restriction on the traffic capacity of the road. An effective argument in favor of automatic roadside signals has been the fact that they "keep the trains moving" and increase the traffic capacity.

The simplest automatic control, one which is in use on urban subway and elevated lines, is an air valve hung on the car truck near the rail level and stop arms operating in conjunction with the fixed signals in such a way that if a stop signal is displayed the stop arm is raised into the path of the air-valve handle and actuates it, thus making an emergency operation of brakes. This system naturally does not meet the requirements just mentioned. Modifications of this simple system involve principally electrical or magnetic controls of the air valve, the operation of these controls depending upon current flowing or not flowing because of the presence of other trains within the danger area. All of these, however, fail to give the necessary caution signal to the engineer at present given by the "distant" block of the roadside signals, but rather operate to stop the train in case of actual danger.

Another system, the author continued, known as the "continuous induction" system, is arranged to supply the indicating energy for the locomotive to the rails of the track circuit in the form of alternating current which is collected inductively on the locomotive. If the track ahead is clear, the detecting apparatus is continuously energized, but if occupied, or if the indicating current supply fails, the locomotive apparatus becomes de-energized and a brake application results.

The problem at the present time is to modify operating rules slightly to fit the limitations of the existing automatic systems, or more fundamentally to develop the automatic control systems in some way so that they will give adequate advance notice to the engineer but will ultimately operate to stop the train in case of human failure in the cab. "Thus," concluded Mr. Blake, "with automatic control in force, it seems likely that the future trend of signal development will be toward cab signals rather than roadside signals—first, because they are inherently capable of giving greater protection, and, second, because they involve less apparatus over and above that required in any case for the automatic control."

Frank J. Sprague declared that the most important tests of train control are now being conducted by the New York Central Railroad. The general requirements of train control were tersely summarized by the speaker, who declared that it must protect but not hinder train operation. Furthermore, apparatus used in train control should not function except when needed, if excessive maintenance cost is to be avoided. About four thousand different schemes have been submitted to the railroads, Mr. Sprague said.

### Automatic Substations and Single-Phase Regeneration Discussed

A discussion of the application and economics of automatic railway substations was the next paper, presented by L. D. Bale of the Cleveland Railway Company. This was the same paper which he presented at the Cleveland Section of the A. I. E. E. last April. Mr. Bale emphasized the economies from the standpoint of distribution efficiency resulting from a reduction in distribution copper on account of establishing a larger number of substation operating points. He dwelt also on the economy of operation without manual operation. He paid tribute to the effectiveness and reliability of the automatic operating equipment, but pointed to the fact that each and every application of this equipment will present a variation of control features by reason of new or different operating conditions. While his experience had been principally with railways, he said that the system was applicable also to Edison direct-current substations, to small hydraulic plants and various other kinds of installations.

L. J. Hibbard presented a paper on systems of single-phase regeneration for use with series-type commutator motors. Mr. Hibbard's paper was essentially a record of accomplishment in advancing the art of regeneration by single-phase motors. Single-phase regeneration is, of course, not new, but it is less advanced in its development than direct-current regeneration. Mr. Hibbard classified the various schemes of regenerative connection for single-phase motors as follows: (1) Series excitation; (2) self-excitation or cross-excitation; (3) shunt excitation; (4) separate excitation. The third and fourth classes have been commercially applied, but, according to Mr. Hibbard, no commercial applications of the first and second have been made as yet.

Mr. Hibbard then gave connections and diagrams for the various classes and discussed a particular method

devised by himself by which he is able to control the degree of regeneration and the power factor at which this regeneration occurs, the second point being the most striking in connection with the problem of single-phase regeneration. In his analysis of this method he developed a vector mechanism by which the various values and the phase relations of voltages, currents and fluxes could be shown graphically by different settings under the control of the operator.

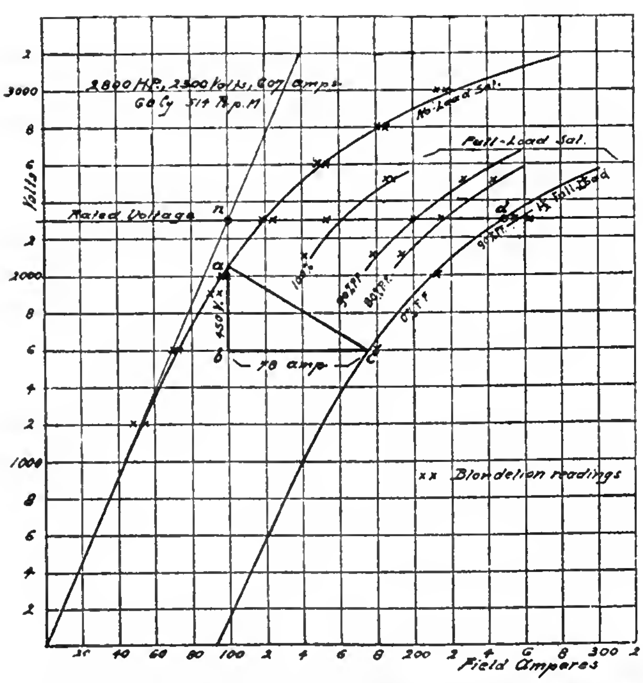
The chief comment on Mr. Hibbard's paper was to the effect that it did not cover commutation. Attention was called to the fact that both alternating-current and direct-current components must be commutated in a machine of the type considered during regeneration. One single way to reduce the alternating-current component is to reduce the flux. This can be done by connecting a reactor around the commutating poles. Shunt excitation is simpler than separate excitation but produces lower power factor, the speaker contended.

### A New Kinematic Device

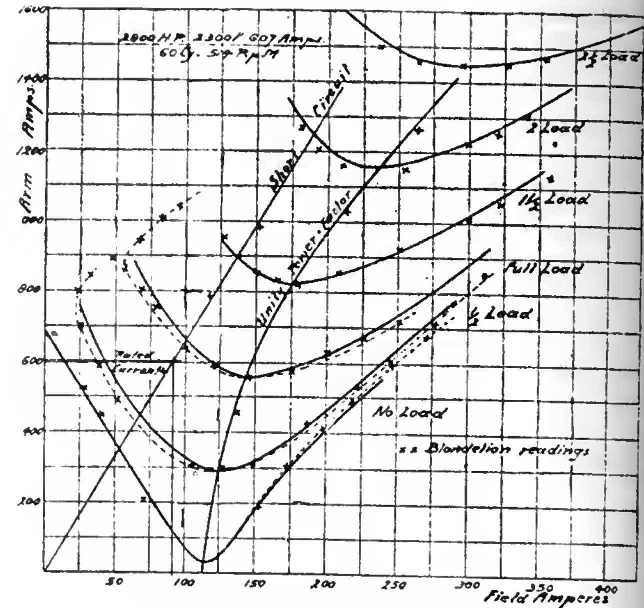
"The Blondelion" was the title of a paper presented by Prof. Vladimir Karapetoff. The "blondelion" is a kinematic device which enables one to compute the performance of a polyphase synchronous generator or motor. It is fundamentally a combination of movable and adjustable bars, linkages and straight and curved guides, and its purpose is to enable a designer to select the best electrical constants and a no-load saturation curve and to "test" a synchronous generator or motor before it has been actually built. There are also other auxiliary uses, such as to take the place of involved analytical and theoretical investigations and to replace circular diagrams, etc.

This "blondelion" is one of several kinematic devices developed by Professor Karapetoff, the others being the "secomor," the "indumor" and the "heavisidion," while still others are under preparation. The first two have already been described before the Institute and the third was described this year.

Professor Karapetoff explained his "blondelion" by



NO LOAD AND LOAD SATURATION CURVES ON A GENERATOR CHECKED BY THE BLONDELION BY CROSSES



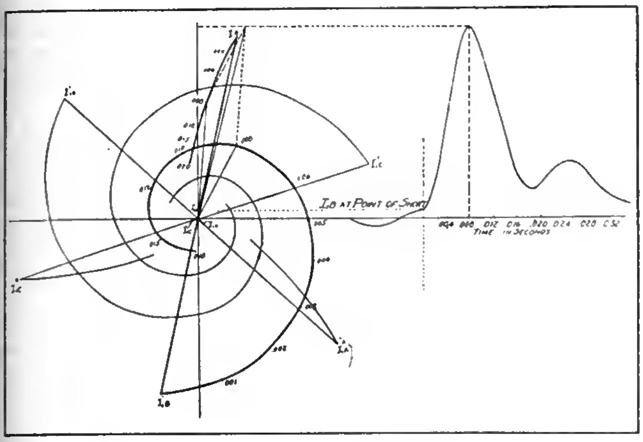
SHORT-CIRCUIT AND V CURVES ON A SYNCHRONOUS MOTOR CHECKED BY THE BLONDELION

an analogy. First he pointed out that it is fundamentally the linking up of four vectorial equations, represented by mechanical linkages, so that when one degree of freedom of motion of the device is allowable, then with any given set of conditions the desired answer may be found. His simple mechanical analogy he explained as follows: It would be possible to set up a scale of lengths of cylindrical tanks and a scale of diameters of cylindrical tanks and a scale of corresponding surface areas of tanks and devise a mechanism, pantographlike, which would, when one point is set at a given length and another has a given diameter, bring the third point to rest at the area of the particular tank; but obviously, if the point were set on a given area, there would be an infinite number of combinations of lengths and diameters to produce that area. Similarly, a scale of tank volumes might be set up to work in relation to the length and diameter scales the same way as the area scale, but again for any given volume there would be an infinite combination of lengths and diameters. However, if a combination mechanism to operate on all four scales were devised and one point were set at a given area and another point were set at a given volume, the other two pointers would together come to rest at one point of each scale, thus giving a definite length and a definite diameter.

Carrying this fundamental principle into the complex synchronous machinery field, Professor Karapetoff devised his "blondelion" to take into account all the variables of the characteristics of the machinery, and in such a way that it could give answers as to all the operating characteristics which one needs or would wish to know about the machine.

The accompanying figures show two sets of curves taken by test from a certain machine and also indicate various points on these curves as calculated by the "blondelion." These show the accuracy of the device.

Prof. W. V. Lyon presented a paper on "Transient Conditions in Electrical Machinery." This paper was essentially mathematical, Professor Lyon having reduced to simple mathematical form various equations of electrical machinery transients. He did this by the introduction of complex angles and complex angular



$R_1 = 0.0172$ $R_2 = 0.0455$
$L_1 = 0.00569$ $L_2 = 0.00996$
$\tau = 0.0483$
Taking into consideration the effective resistance
$m'_1 = 96 + j360$ $m''_1 = 60.4 + j17.5$
$I_{1B} = 90.5 \sin 85°$

$$i'_{1B} = I'_{1B}\,\epsilon^{-96t} \sin (360t + 258°)$$

$$i''_{1B} = I''_{1B}\,\epsilon^{-60.4t} \sin (17.5t + 78.3°)$$

FIG. 1—VECTOR DIAGRAM UPON WHICH NO LOAD ANALYSIS WAS BASED

velocities added to the complex vector representation hitherto employed. The paper, therefore, presented no particularly new theory with reference to the transients in machinery, but rather a new method of attack on the problem of their calculation.

Prof. A. E. Kennelly, in the absence of Professor Lyon, presented the paper, commending it as showing a method which was practical in its application. J. O'R. Coleman, a research associate of Professor Lyon, showed the results of tests which he had performed under the direction of the latter to check experimentally a part of the theory presented. The tests were performed on a General Electric 75-hp., three-phase, 900-r.p.m., 220-volt induction motor operated as a generator.

Mr. Coleman presented three slides. Fig. 1 gives the vector diagram upon which the analysis is based for the short circuit at no load. The vectors $I_{1B}$, $I_{1C}$, and $I_{1A}$ represent the current in the three phases just before short circuit, assuming that a short circuit begins just before $I_{1B}$ is at a maximum, the vectors being in the position shown. At this moment $I_{1B}$, for example, breaks up into two components, $I'_{1B}$ and $I''_{1B}$. After the short circuit occurs the terminus of the vector $I'_{1B}$ travels along the logarithmic spiral shown at the velocity of 360 circular radians per second and is damped at the rate of 96 hyperbolic radians per second, all based on 60-cycle operation. $I''_{1B}$ travels along its spiral as shown with a velocity of 17 circular radians and a damping rate of 60 hyperbolic radians per second. At any specific time the positions of $I'_{1B}$ and $I''_{1B}$ and their instantaneous lengths may be found, and their vector sum projected on the time axis gives the instantaneous value of current in phase B at that moment. Similarly the current at any other moment in any phase may be found.

An oscillogram was taken of the short circuit (see Fig. 2). It will be noted that the short circuit in phase C came for some reason just a little after that in phase A and B, and the calculation was based on a compromise time just before phase C was short-circuited. Fig. 3 shows the actual oscillogram compared with the calculated values as obtained from the vector diagram described. For phases A and B the agreement is very satisfactory, but for phase C there is a slight disagreement, doubtless due to the time lag of the actual short circuit in that phase.

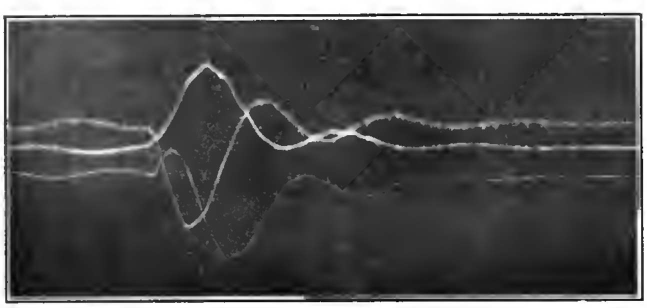
Thus, Mr. Coleman pointed out, the experimental results indicate that the calculated results are sufficiently close to be of practical use.

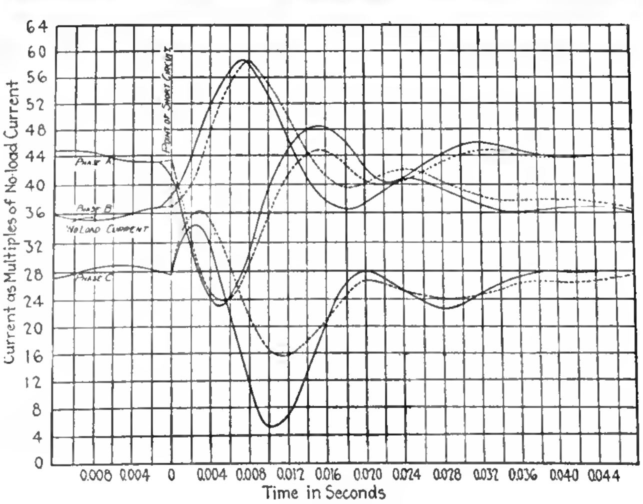
A desire to have the transients in transmission and distribution systems studied in a similar manner to that used with rotating machinery was expressed by D. W. Roper, who offered the system of the Commonwealth Edison Company for checking any theoretical or laboratory conclusions.

Prof. V. Karapetoff expressed the belief that Professor Lyon's method could be applied more extensively, but warned scientific men against working for approximate results. Accuracy should be the aim, he declared. For example, he referred to the mutual induction of primary and secondary coils in rotating machines, saying that it depends upon their relative position and hence is a function of time, $T$.

A paper by A. L. Atherton, entitled "1922 Developments in Auto-Valve Lightning Arresters," closed the session. Mr. Atherton said that his paper was primarily an outline of auto-valve lightning-arrester development, an outline of the progress of which was presented at the midwinter convention of 1922. In the issue of the ELECTRICAL WORLD for last week, page 385, an article by Mr. Atherton appears on the performance characteristics of these auto-valve lightning arresters. His convention paper was fundamentally a discussion of the theory involved in the development of the arrester and a record of the tests which had been made to determine some of their technical characteristics.

The auto-valve arrester received several commendations, but some questions were raised by E. E. F. Creighton as to how a glow discharge (on which the





- - - - - Calculated curve.
———— Oscillogram.

FIG. 2 (ABOVE)—SHOWS AN OSCILLOGRAM OF A SHORT CIRCUIT AND FIG. 3 SHOWS THE ACTUAL OSCILLOGRAM COMPARED TO THE CALCULATED CURVE

action depends) can be maintained at the current densities which occur; also, how the detonation accompanying a discharge at three times voltage can be withstood with the construction employed. Dr. C. P. Steinmetz commented chiefly on the advantages of using a large-capacity direct-current high potential to simulate lightning discharges and thus test arresters under conditions comparable with actual service. The time is rapidly approaching, he declared, when arresters can be tested for performance as accurately as rotating machinery. Attention was, however, called to certain obstacles that must be overcome first.

D. W. Roper reported that several of the auto-valve arresters had been subjected to service tests on the Chicago system in comparison with other types. Very favorable results were obtained with the new type, and more units are being placed on the system. The only auto-valve arresters that did fail protected their apparatus and then were damaged by the highest voltages recorded on the system.

In closing, Mr. Atherton emphasized that virtually the only failures of the auto-valve arrester have been due to flashover destroying the insulating enclosure. He also pointed out that this arrester is a high-speed device and shows no signs of internal impairment after discharging heavy currents successfully. No power current follows the discharge, indicating that the glow discharge, upon which the action depends, is maintained.

Commenting on the breakdown of the gaps involved in the auto-valve arrester, Dr. Slepian contended that until a gap becomes less than one wave length of light it cannot break down at less than 350 volts. Between plain electrodes the breakdown voltage is a direct function of the amount of gas between electrodes.

## Thursday Afternoon Devoted to Machine Switching and Radio

On Thursday afternoon a large audience listened to the presentation and discussion of three notable papers on communication. A paper on "Machine Switching Telephone Systems for Large Metropolitan Areas," by E. B. Craft, L. F. Morehouse and H. P. Charlesworth, was presented by Mr. Morehouse. This paper gave the historical development of communication methods, described the present A and B board manual operation, and then discussed the metropolitan application of the panel type of machine switching.

In discussing machine switching the authors pointed out that the functions to be performed by the telephone subscriber in getting a connection must be simple and easily understood. It must work efficiently and with accuracy and speed. The system must not require modifications in the existing rate structure which are otherwise not desirable. The system should employ, as nearly as practicable, the conventional numbering scheme. It should work with the existing telephone network, so that its introduction will not require wholesale number changes and extensive rearrangement or the abandonment of existing switchboards or other plant. Its introduction must, of necessity, be on a gradual basis and must be sufficiently flexible in design in order to care for growth and also for changing traffic conditions.

The authors then followed with a description of the routine of the machine-switching operation, as follows:

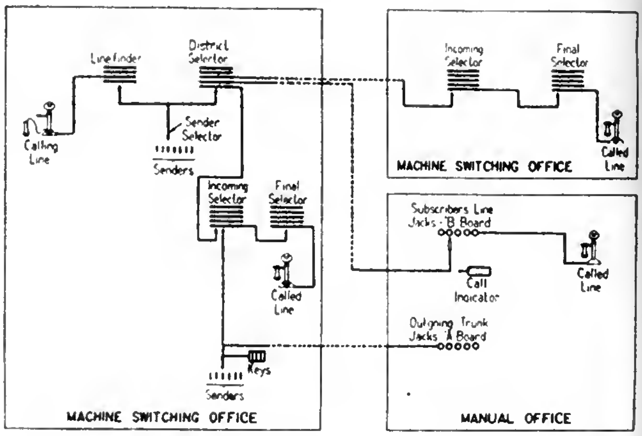
The progress of a call originating in a machine switching office is briefly as follows:

The line of the calling subscriber, who is assumed to be a subscriber in the Academy office, appears in a so-called "line finder" frame. When the subscriber's receiver is removed from the switchhook preparatory to dialing, the line is selected by a "line finder" and connected to an idle "sender" by means of a "sender-selector."

Upon completion of these operations, which take but a fraction of a second, the dial tone is sent out to the calling subscriber as previously mentioned. When the subscriber dials, electrical impulses on a decimal basis are transmitted to the sender, which receives and registers them, translating them in turn to the proper basis for the control of the selectors which are not operated on a decimal basis. The sender automatically causes the particular "district selector" which is permanently associated with the line finder originally used to select a trunk to the office desired.

Assuming that the call is for a subscriber in the same office, Academy, the trunk chosen will terminate at an "incoming selector" frame and the sender above referred to will cause the call to be routed through the incoming selector to a final selector, and thence to the particular line desired. When the connection is thus completed, audible signals will be sent back to the calling subscriber to indicate that the station is being rung or that the line is busy.

If the call had been for a subscriber in another machine switching office, namely, Pennsylvania, the call would be routed from the district selector to the office desired, either directly or through an "office selector" in case the total



SCHEMATIC DIAGRAM OF THE CONNECTIONS AND EQUIPMENT NECESSARY IN MACHINE SWITCHING

number of trunks to all offices is too large to be placed on the district-selector multiple. These trunks terminate on incoming selectors at the Pennsylvania office, which select the subscriber's line through final selectors, as described above.

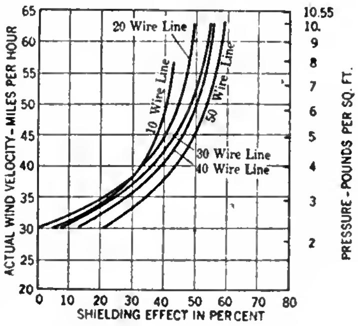
If the call is for a subscriber connected to, say, the Worth office, which is a manual office, the call would be routed from a district selector directly or through an office selector to the "B" board in the Worth office, where the number desired would appear in front of the operator at a "call indicator position" in the form of visible numbers on the keyshelf. The operator is advised of the trunk to which the call is connected by suitable signals, and the call is completed by plugging this trunk into the desired subscriber's line.

Calls originating in a manual office and intended for a machine switching office reach the machine switching office over trunks from the "A" operators in the manual office. At the machine switching end these trunks terminate in incoming selectors, which have access to the final selectors on which the subscriber's lines are located. The selectors are under the control of a special group of senders, and operators are provided with suitable keys for setting up in these senders the number of the desired subscriber. These operators at the machine switching office receive the information as to the desired number from "A" operators in the distant manual office, exactly as is done in the case of manual operation.

The paper then took up the detail apparatus and its functioning in bringing about the desired operation. Several prominent telephone engineers discussed this paper and elaborated on the engineering and development work required to produce the system, pointing out

the effect of the adoption of the machine-switching practice.

In a paper entitled "Wind Shielding Between Conductors of Telegraph and Telephone Lines," F. J. Howe gave a description of some very valuable tests made to evaluate the effect of wind on conductors. The experimental work may be summarized as to results by the conclusions of the paper:



VARIATION IN SHIELDING WITH WIND VELOCITY

1. The formula $P = 0.0025\ V^2$, in which $P$ is the pressure in pounds per square foot of projected area on cylindrical surfaces, and $V$ is the wind velocity in miles per hour, may be used in calculating wind pressures on *unshielded* ice-covered conductors.
2. A definite shielding effect exists between ice-covered telegraph and telephone conductors carried on the same cross-arm and closely spaced (about 12 in. center to center) as in modern telegraph and telephone practice.
3. A similar shielding effect also exists between such wires carried on different cross-arms spaced 2 ft. apart.
4. The amount of shielding on any number of wires increases with the wind velocity and vice versa.
5. The shielding at any wind velocity varies with the number of wires, increasing as the number of wires increases and vice versa.
6. On telegraph and telephone lines having conductors coated with ice ½ in. in radial thickness the total shielding effect at wind velocities corresponding to a pressure of 8 lb. per square foot, even allowing a 10 per cent reduction from the test results in order to compensate for possible inaccuracies, will run from a minimum of 39 per cent on a ten-wire line to as high as 51 per cent on a fifty-wire line.

In the discussion which followed Mr. Howe's paper there was general agreement that a valuable contribution had been made to a subject which had never permitted exact conclusions; yet it was pointed out that the allowances now used for wind shielding effects were on the safe side.

The last paper of the session was entitled "The Wave Antenna" and was by H. H. Beverage, C. W. Rice and E. W. Kellogg. It was presented by Mr. Kellogg. The paper was an elaborate theoretical treatise and afforded opportunity for a splendid treatment of a highly specialized subject.

The wave antenna is a new type of highly directive antenna used by the Radio Corporation on Long Island. It consists of two copper wires, 9 miles long, strung on poles, and it is said to receive transatlantic messages. This type of antenna is considered a marked advance in that it reduces interference and "static" and also is aperiodic and a good energy collector. A mathematical analysis of the performance of the antenna was given, with a description of accessory details.

The theoretical problems and practical accomplishments were dealt with by the authors in connection with the Riverhead antenna of the Radio Corporation and curves and oscillograms were used to bring out the phenomena associated with the action of the antenna.

By a process of balancing, it is possible to produce a "blind spot" or direction of zero reception, at any angle more than 90 deg. from the signal. One method of obtaining this result is by producing reflections of certain phase and intensity at the end opposite to the receiver. Reflections at the receiver end of the antenna, on the other hand, do not alter the directive properties of the antenna.

## Electrophysics Session on Friday Morning Has a Warm Discussion on Fundamentals

On Friday morning a group of five papers was presented under the auspices of the electrophysics committee. In the paper on "Dissymmetrical Electrical Networks" written and presented by Dr. A. E. Kennelly it was pointed out that the solution of complicated networks when symmetrical could very readily be obtained by replacing the network with equivalent $T$ or $\Pi$ lines. When the network is dissymmetrical the system can be replaced by two symmetrical systems and a terminal load, by two symmetrical leak systems and a leak load or by a new development of the author in which the solution is obtained by using angles, the geometrical mean surge impedance and the inequality ratio.

Prof. F. S. Dellenbaugh, Jr., in discussing the paper, pointed out that the methods indicated by Dr. Kennelly had a wide practical application. He cited an instance in which an engineer had taken a day to solve a network problem while a young student familiar with the method of Dr. Kennelly had solved the problem in half an hour. The system requires the use of hyperbolic angles, but is relatively simple as to mathematical operations and far quicker and more accurate than the method which involves the laborious application of the generalized Ohm's law.

The "Physical Interpretation of Complex Angles and Their Functions" was the topic of a paper by A. Boyajian. In this paper the author reduced to simple terms, meanings and usages many of the so-called complicated terms now used in angular calculations. He treated angles as percentages and pointed out that, for example, a 1 per cent line drop in phase with the voltage really was 1 per cent of a hyperbolic radian, which could be changed to degrees by multiplying by 57.7—i.e., 5.77 deg. In a similar manner a quadrature drop—for example, 1 per cent—is really 1 per cent of a circular radian, which could be expressed in degrees in a similar manner—i.e., 5.77 deg.

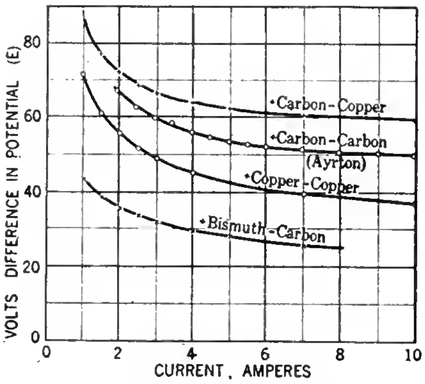
Prof. V. Karapetoff stated that Mr. Boyajian had made a valuable contribution to the literature by so clearly and lucidly interpreting mathematics of a complicated character. Dr. Kennelly also complimented the author, but pointed out that when dealing with hyperbolic angles rotation must be considered.

A notable paper entitled "Radiation from Transmission Lines," by Charles Manneback, was presented by Prof. F. S. Dellenbaugh, Jr. This paper dealt with the loss of energy due to radiation in low-frequency transmission lines and, taking exception to the opinion of Dr. Steinmetz, proved that radiation was negligible.

The problem, the author showed, involves a study of what might be called time-three-dimensional space transient, while the most complicated transients considered in electrical engineering are time-one-dimensional space transients. The distribution of current along the conductors of a line was shown to be a very close approximation to the actual, unknown distribution with regard to the possibly existing radiation. Then, from this assumption, the radiation of the system was calculated at a corresponding approximation and its amount found to be negligible compared with the heat dissipated in the line during the same time. From this it was concluded that the effect of the radiation

upon the attenuation and the distortion of the waves along the line must also be negligible, compared with the effect of the joulean losses.

An application to the steady radiation from a transmission line oscillating freely at one of its natural frequencies showed, even at very high frequencies, that the power radiated was negligible compared to the heat dissipated. For instance, a 100-kw. transmission line, No. 00 B. & S. wire, oscillating at 3,000,000 cycles per second, wastes by radiation only one-thirty-six-hundredth part of what is wasted by heat. The influence of this radiation on the attenuation and distortion of the traveling waves was thus found entirely negligible in engineering practice. Professor Karapetoff agreed with the author in his conclusions as did Dr. Slepian. Dr. Slepian pointed out that radiation occurred only when reflections were present and showed how Newton's law applied. Even with reflection present, the effect of radiation is negligible, he observed.



VOLT-AMPERE CHARACTERISTICS WITH THE ARC LENGTH CONSTANT

A paper entitled "A New Equation for the Static Characteristic of the Normal Electric Arc," by W. B. Nottingham, discussed the arc formed between any electrode materials and for any length of arc. The author found that if the length of the arc is constant, the equations of Aryton and Steinmetz can be written as

$$E = A + B/i^n,$$

in which $A$ and $B$ are constants dependent on the arc length and electrode material, while the exponent $n$ depends only on the electrode material and is found to be directly proportional to the absolute temperature of the boiling point of the anode material.

Using this equation as a basis, the author then studied the effect of arc length and developed a three-term equation for arc characteristics which checked well with many experimental observations. The author was highly complimented by several members on his contribution to research.

A paper that brought out spirited discussion was written and presented by Dr. Carl Hering under the title "Electromagnetic Forces: A Search for More Rational Fundamentals; A Proposed Revision of the Laws." The paper was premised on several experiments allied to the pinch and stretch effects and contained conclusions by the author that existing conceptions of electromagnetism were erroneous or at least subject to question. The author also presented a new generalized law based on the proposition that "in any system such motions will tend to take place as will reduce the potential energy of the system." The experiments were qualitative and the deductions of the author were to the effect that longitudinal forces due to magnetic fields were present. The author explained the force actions by use of the production of a counter-emf. and a connection between the flux and the conductor.

C. O. Mailloux opened the discussion with an attack on the Maxwellian system of mathematics and supported Dr. Hering's contention that investigation was needed. He indicated the possibilities of an investigation of the theory that magnetism was elastic in physical behavior and gave a fine résumé of the evidence and opinions which exist for present theories.

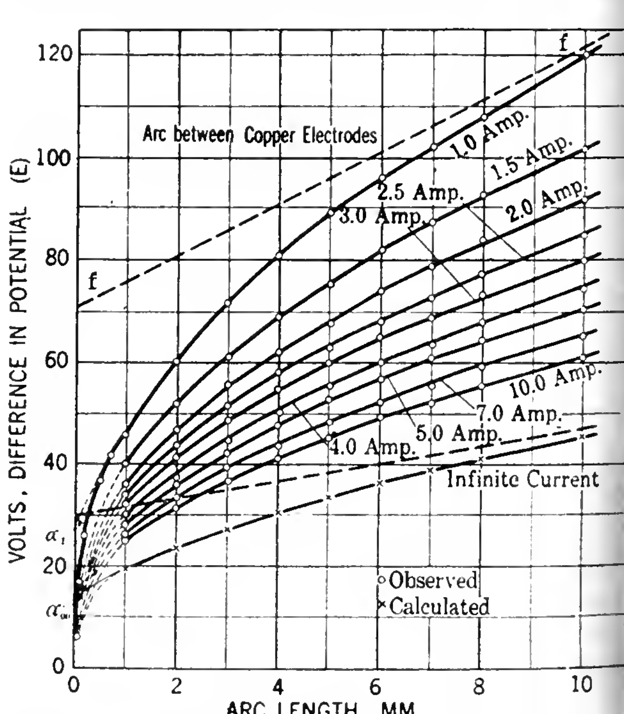
Professor Karapetoff pointed out just what Maxwellian and Kelvin mathematics represented and stated that the mathematics was a separate entity from the physical nature of electricity and magnetism. The latter is largely still theoretical, while the former gives quantitative and accurate results for all cases known in the paper. He indicated his belief that each of the experiments could be explained on the basis of complete and partial linkage changes and stated that the coefficient of self-induction was a quantitative criterion for determining the accuracy of the experiments.

Professor J. H. Morecroft agreed with Professor Karapetoff that the experiments were not conclusive because qualitative and said that they could all be explained by present laws. He indicated, as did Professor Karapetoff, an intention to carry out quantitative experiments of a similar character.

John Mills supported Dr. Hering in his contention that a revision of existing laws was necessary, but stated his belief that all the experiments could be explained on the basis of electronic effects and that flux and magnetism unnecessarily complicated the problem. Other discussion occurred without conclusive results, but the general opinion was expressed that the paper was stimulative to thought and valuable for its experiments.

### Effect of Minor Hysteresis Loops Approximately Calculated

In his paper on "Permeability," Thomas Spooner discussed the application of mathematics and graphs to determine the effect of minor hysteresis loops on the behavior of iron used in telephone transmitters, radio



VOLT-ARC LENGTH CHARACTERISTIC FOR DIFFERENT CURRENT VALUES

transformers and similar devices in which alternating current and direct current are superimposed. His paper showed the resultant equations and methods for getting approximate quantitative results.

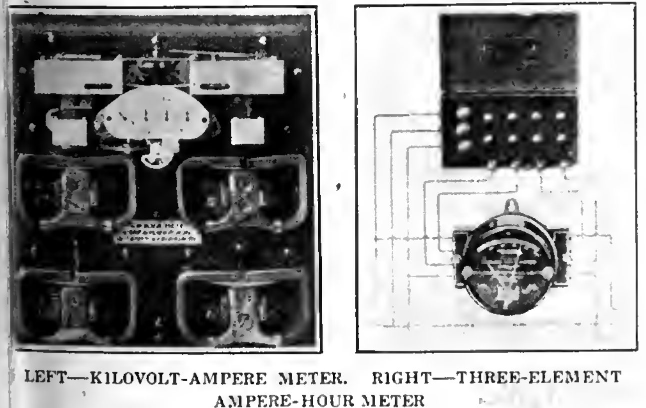
## Metering and Meters Discussed Friday Afternoon

In a paper entitled "Applications and Limitations of Thermocouples for Measuring Temperatures," by I. B. Smith, which was presented by title, the author summarized the practical applications of the device and the errors that may occur in use. He pointed out that the thermocouple was now greatly used in the precision measurement of the temperature of feed water, flue gases, bearings, windings, cables, etc., and that in these many uses care must be taken to eliminate errors. He discussed ten sources of error that may occur and pointed out how to eliminate or anticipate their effects. He then discussed rules and methods for measuring temperatures and showed the necessity for standardization if comparable results are to be obtained.

The use of thermocouples for measuring temperatures in underground cable systems has been very successful, according to E. D. Tanzer of the transmission department of the Philadelphia Electric Company. He described one instance where thermocouples were used in a 400-ft. duct line at intervals of 50 ft., with all the leads brought back to one point for reading the temperature value. In this way very accurate indications of conditions met with in underground systems can be obtained. A unique use of thermocouples was cited where a break in an underground steam main was located by making temperature tests throughout the length of a duct line running near the steam main, the location of the broken portion being indicated within a few feet by the abnormal temperature shown by the indicator.

G. H. Cole, in speaking of the inaccuracies encountered in the use of thermocouples, said that the greatest cause of trouble was in the contact drop at the thermocouple itself. He advocated that the leads be attached to opposite sides of the active material instead of on the same side.

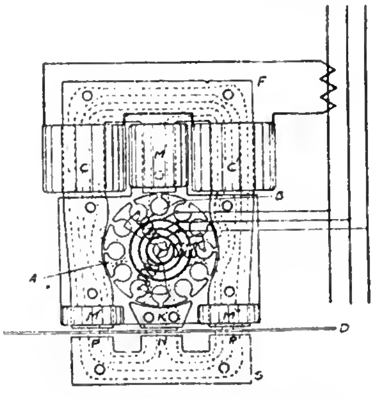
In a paper entitled "Volt-Ampere Meters," R. C. Fryer gave a résumé of meter developments and illustrated existing types as applied to metering kva. He tabulated the types as they involve different principles as shown in the accompanying table. Mr. Fryer then discussed each type and its application advantages and disadvantages and indicated a belief that the kilovolt-ampere meter will be on a plane with the kilowatt-hour meter in a few years.



LEFT—KILOVOLT-AMPERE METER. RIGHT—THREE-ELEMENT AMPERE-HOUR METER

P. A. Borden discussed the Lincoln-type meter, which is largely used in the system of the Hydro-Electric Power Commission in Canada, and said good results had been obtained.

In regard to a question as to actual meters on the market, Mr. Fryer stated that the meter manufacturers were prepared to give almost any kind of measuring instrument to the industry, but that the industry was as yet very undecided as to just what it wanted. This was brought about by the fact that so many different clauses relating to charges in billing for low power factor were in use. As stated in the original paper, of the 418 utilities in cities of 20,000 or over in the United States and Canada, fifty-nine companies have clauses considering power factor, and of these there are twenty different kinds.



ONE ELEMENT OF AN ANGUS THREE ELEMENT METER

The consensus of opinion seemed to be that accurate volt-ampere meters were very much needed and that developments in the past year on this type were very encouraging. Among those taking part in the discussion were Charles Fortescue and E. P. Peck.

TYPES AND MAKERS OF VOLT-AMPERE METERS

| | | |
|---|---|---|
| (1) Proper-phase-relation-type meters | Full range | Bodi (Westinghouse) |
| | | Angus (Esterline-Angus) |
| | Fixed range | General Electric |
| | | Lincoln |
| (2) Resultant-type meters | Full range indicating | Lincoln |
| | | Sangamo |
| | Full range integrating | Sperti-Bleeksmith |
| | | (Westinghouse) |

A notable paper entitled "The Measurement of Power in Polyphase Circuits" was presented by Charles Fortescue. It showed the necessity for reconsidering the present commercial trend in power measurements. Although meters and rate systems account for power factor and demand elements, unbalance is not considered and an inequitable application of power-factor penalties occurs in many cases. He stated that unbalanced effects were of the same order of magnitude as reactive kva. effects in many cases and showed that the consumer often was charged for reactive power or unbalanced power consumption brought about by other consumers' apparatus. He then introduced the sequence idea of power measurement and proposed a new method.

The proposal made was that the positive phase-sequence power output only be measured and the power charges be made on the basis of this measurement. It was further proposed that the unbalanced kva., which is the product of the positive sequence voltage and the negative sequence current, be measured either by means of a negative sequence ammeter, indicating or recording, or a kva. meter, and a charge made for the amount of unbalance. The user of symmetrical polyphase rotating machinery should then pay a lower rate, based

on the estimated cost of unbalance, and the consumer having unbalanced loads should be charged directly for the amount of unbalance he creates, or else should have his positive phase-sequence power rate increased, based upon the estimated cost of unbalance. Devices for measuring these quantities are being developed, the author said, and the outfit for making these measurements will be no more complicated than the present existing measurement devices. In fact, the tendency is toward greater simplicity.

In presenting the subject the author had no intention of suggesting how rates should be made, but merely wished to point out what factors enter into the question of equitable rates when the polyphase system is subject to unbalance.

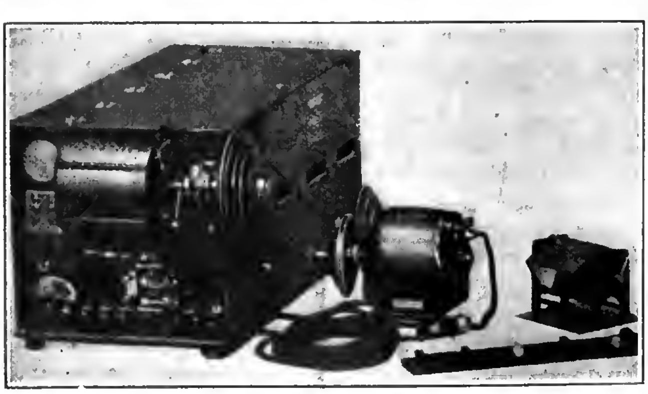
R. D. Evans discussed the paper and showed that metering devices could be made to measure sequence quantities. Standard instrument transformers and meters could be used, and in addition an auxiliary box containing the necessary network impedance. In his opinion, fewer meters would be required than with existing methods.

E. P. Peck said that any factors that cannot be readily understood by the power consumer cannot be used in billing a customer for the energy consumed. Consequently it is inadvisable to bring in a factor such as unbalance of load, particularly as this is not one of the main factors that affect the rates. Varying load factor, total load and the initial cost of equipment utilized in stations and the distribution systems are much more important. In his opinion, billing on a kva basis was one of the best methods, as this can be understood more readily by the general consumer.

Professor Karapetoff was also of the opinion that the rate basis must be easily understood. He explained a simple mechanical analysis that might simplify the problem of making the unbalanced condition understandable to the consumer.

### A New Type of Oscillograph

A paper that brought out a great deal of discussion was entitled "Expansion of Oscillography by the Portable Instrument." The author, J. W. Legg, described a portable oscillograph of a new type. The three galvanometer magnets are of the permanent type, and the resistors and shunts are in the oscillograph box. An incandescent lamp with arrangements for getting abnormal voltage for the time of film exposure and



GENERAL ASSEMBLY OF COMPLETE INSTRUMENT

the use of 110 volts alternating current or a storage battery for motive power are other distinctive features of the instrument. The author showed the many fields of application and presented oscillograms of typical cases. J. R. Craighead discussed the paper and asked several questions of the author in regard to heat radiation and the voltage range of the resistors, the insurance of lamp brilliancy when photographing transients, total weight of box, etc. He also said he had used the older type of oscillograph for many types of field

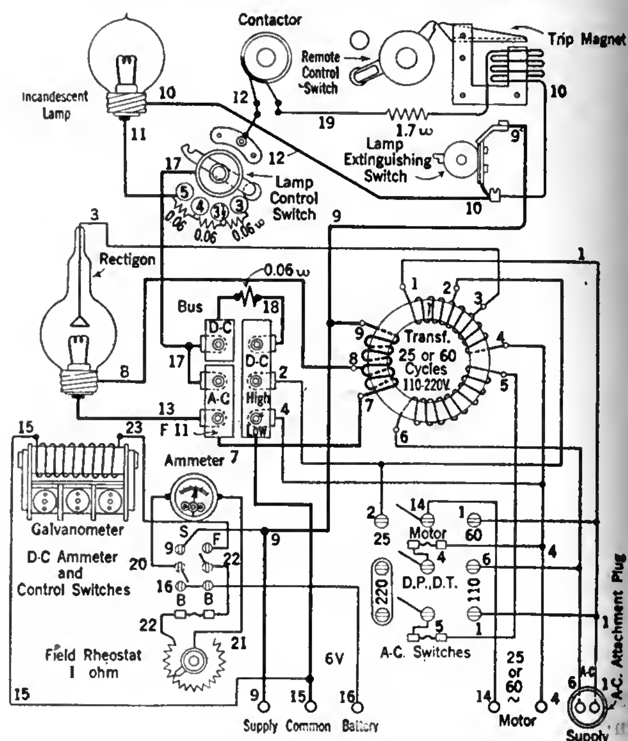


DIAGRAM FOR SUPPLY CIRCUIT FOR MOTOR, LAMP, ETC., IN OSCILLOGRAPH

applications. P. A. Borden gave examples of using oscillographs in logging camps, isolated power plants, under tents, etc., and said they were great assets to an operating engineer.

The use of tungsten wire in air as an element for producing the intense light necessary for the mirror and film was suggested by H. L. Curtis. The use of aluminum mirrors instead of silvered glass was also suggested. The great advantage of this would be that electromagnetic damping of the elements could be accomplished, thus doing away with the present use of oil for this purpose. A method of keeping silvered mirrors was suggested by E. D. Doyle. He had had very successful results in placing the elements in a glass bottle instead of in oil, placing a waxed paper around the stopper to exclude all injurious elements. Others taking part in this discussion were E. E. F. Creighton, Charles Fortescue, G. H. Cole and R. C. Fryer.

### A New Crest Voltmeter Developed

In a paper entitled "Measurement of Transients," F. E. Terman described a new type of transient-crest meter and listed applications suited to its use. The new meter utilizes the vacuum tube and goldleaf electroscope operations. It consists of a goldleaf electroscope in series with a rectifying device and an electron tube which enables the electroscope to charge but prohibits discharge. The charge that is captured in this manner is proportional to the maximum impressed potential, and where adequate insulation is possible will remain substantially undiminished for many seconds or even minutes after the transient has passed by.

The crest meter has already served successfully in

several investigations. The first application was the measurement of the potential of the sphere electrode of a high-voltage oscillator. The method followed consisted in measuring the charging current to the sphere by means of a shielded electroscope resting within this electrode. When combined with a second goldleaf acting as relay contact to give an alarm at a given voltage, the instrument is admirably suited for the study of transmission-system disturbances, for the observer need be tied no closer to the test than to remain within hearing distance of an electric bell. Such an application was made during four months of the past summer on a 110-kv. line belonging to the Pacific Gas & Electric Company in an effort to discover the cause of apparently unprovoked flashovers which this particular line experienced from time to time. Similar applications become evident as their need arises.

### Time and Voltage Must Be Considered

In discussing Mr. Terman's paper, Charles Fortescue stated that what was really needed for studying transient phenomena was a method in which the "voltage plus that of time" condition could be measured. The destructiveness of transients is not the result of the high voltage alone, but of a combination of voltage extended over time. Take, for example, transients set up in transformers when they are connected or disconnected from lines. Here the voltage maximum reaches three or four times the normal value, but damage is very seldom caused, because the duration of the transient is so short. In regard to the question of current lag in the electron tubes used in the device described, Mr. Terman stated that there was no lag whatsoever.

A paper on "Balance Methods in Alternating-Current Measurement" was presented by Perry A. Borden. The author pointed out the value of balance methods of measurement, discussed the different methods in a review of the subject and described how the methods were applied to measurements on an operating system. A fine bibliography of the subject formed part of the paper. This paper was discussed by Charles Fortescue, I. M. Stein and E. D. Doyle and the general opinion expressed that the methods outlined by the author could be used to advantage in many applications. The author was complimented on his thorough analysis of the subject and his good presentation of existing methods.

# Practical Data on Lightning

**Effect of the Disturbances in Twenty Transformer and Six Generator Failures and Seven Faults in Other Apparatus Related**

PRESENT-DAY apparatus for protection against dangers caused directly or indirectly by lightning are very incomplete and far from satisfactory, according to views expressed by Sigur Rump in the *Brown-Boveri Mitteilungen* for November and December of last year. He has undertaken an exact investigation of all lightning disturbances coming to his knowledge, developed a general theory of the cases and arrived at conclusions concerning the best protection for each trouble. A total of twenty transformer failures, six generator failures and seven faults on other apparatus were studied.

Flashovers in transformers appeared almost exclusively between coils or between layers—very rarely between turns—and occurred mostly when the transmission line lashed against ground. The end turns were damaged mainly in small transformers (below 70 kva.), while on larger machines the burn-out occurred most frequently toward the middle of the winding. Oil-immersed transformers suffered much less from flashovers, because many overvoltage disturbances are of a very transient character and because it takes an appreciably longer time to puncture a gap under oil than it takes in air. It was found that punctures between the end turns are due to waves with a steep front, while failures in the middle of the winding are caused by internal oscillations within the transformer. Failures between phases have never occurred. A hypothesis is developed to explain the generation of traveling waves with flat and with steep fronts along lines within the field of a thunder cloud. Only a direct hit into the line will, as a rule, cause waves with steep fronts, according to the article. An attempt is made to explain how internal oscillations occur in transformers and how electromagnetic pulsations in a winding may be responsible for a breakdown between coils at any part of the coil stack.

### Three Causes of Lightning Discussed in Detail

Three typical lightning cases which occurred in practical service are related, with all details. One caused an arcing ground, the second set off a train of steep front waves, and the third was a direct hit into a line. Experiences with high-tension lines seem to indicate that lines above 100,000 volts suffer rarely, if ever, from lightning troubles and do not need any protective apparatus. The magnitude of steep-front waves in plants of less than 100,000 volts may easily reach, and in many cases exceed, the flashover voltage of the line insulators. The best protection for these plants and lines would be the complete prevention of the occurrence of overvoltages, such as is afforded by one or more ground cables above and along the entire line, provided that steel towers are used. But this would be far too expensive. It has been tried in vain to block the passage against surges with small choke coils of the so-called "bedspring" type (inductance usually between 0.1 millihenry and 0.5 millihenry). In some cases these coils have even increased the electric stresses. Horn-gap arresters with a resistance in series have been suggested, but they were found to be useful only below 15,000 volts. Theoretical considerations proved that if the ohmic resistance of the gap is considerably larger than the wave resistance of the line, the protective value of the horn decreases to zero.

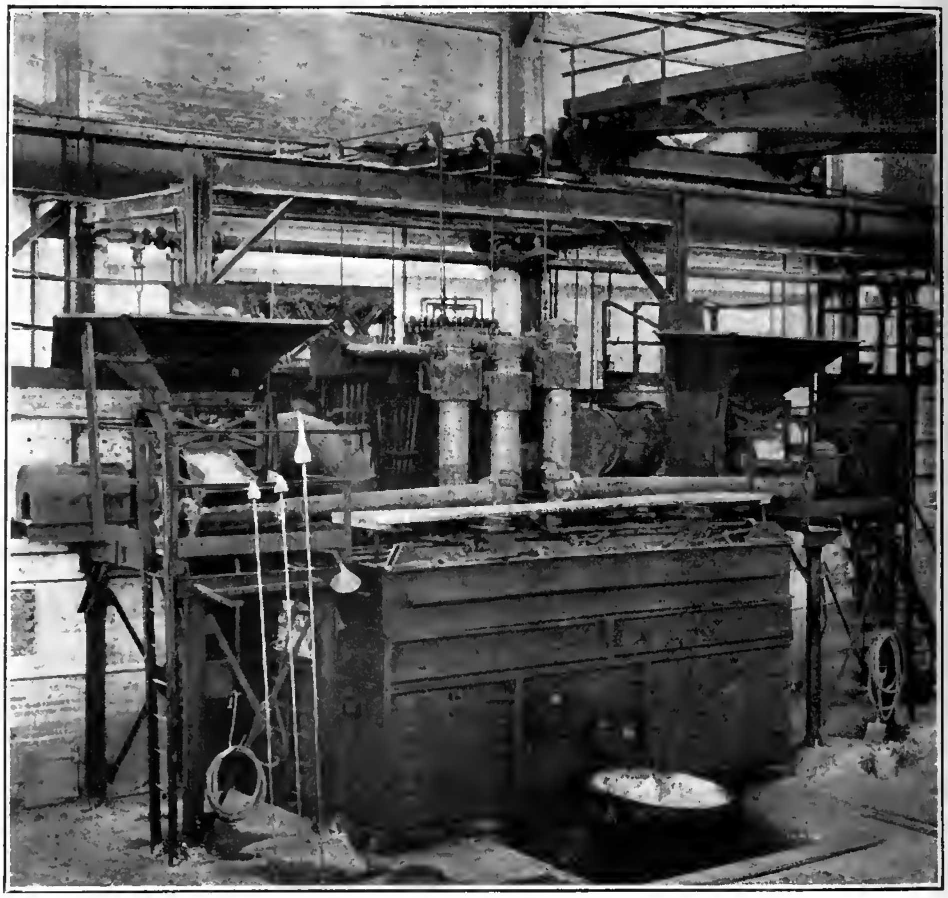
### Chemical Arresters Condemned

The chemical arresters are of little use, because their start depends upon the puncture of a solid dielectric, which takes too long a time to be of any value for quick transients. In many power stations feeding high-voltage lines nearby power consumers are frequently supplied directly with the generator voltage. This, the author points out, is a dangerous practice, because overvoltage troubles on these subordinate branch lines are apt to endanger the main generators. For such cases a one-to-one ratio transformer is recommended, acting merely as an insulating transformer. In the worst conditions possible an incoming overvoltage may burn out this small and inexpensive transformer, but it prevents harm to the costly main generators.

# Electric Furnace Makes Ferro-Vanadium

## Description of a New Electrometallurgical Process for the Reduction of This Material by Carbon—Operation Has Been Made Possible by the Development of a Type of Electric Furnace Different from Those Previously Designed

By B. D. SAKLATWALLA* and A. N. ANDERSON†



THE 80-TON, 4,000-KW. FURNACE USES THREE 12-IN. GRAPHITE ELECTRODES. ROLLERS PERMIT EASY MOVEMENT FOR RELINING OPERATIONS

BY A SERIES of experimental and analytical electrical developments it has been made possible to attain physical electric furnace conditions for the carrying out of a chemical reaction hitherto not commercially possible. Not only has this electric development substituted coke in place of expensive metallic reducing agents but it has also made feasible the reduction of low-grade raw materials. Probably in no other electric furnace operation are materials treated which carry not more than from 2½ to 3½ per cent of the element to be reduced and a commercial product obtained in a single smelting operation.

The commercial production of ferro-vanadium has until very recently been carried on by means of metallic reducing agents such as aluminum and silicon, the former as a self-propagating exothermic reaction without the aid of extraneous heat, the latter in an electric furnace. The cost of such metallic reducing agents has necessarily been excessively high. The attempt, therefore, to reduce vanadium by means of carbon seems natural, and such efforts date back to several years. Moissan as early as 1894 attempted to reduce vanadium in his electric furnace without success, obtaining a highly carbonaceous product, the major portion of it being a carbide. Efforts in this direction by others seem to have been equally fruitless.

The underlying reasons for the difficulty of reducing vanadium by carbon may be ascribed to two main factors—the high temperature of reduction and the great chemical activity of vanadium at such high temperatures. Further, vanadium exists in several forms of valency, producing different oxides with greatly varying degrees of refractoriness and reducibility. In working out a successful process these factors were kept in view and conditions established during the process such as to overcome the inherent deficiencies. The high temperature of reduction was met by designing a small crucible with close spacing of electrodes, causing a very high power input per unit of crucible section. To offset the chemical activity of the metal the furnace was so designed that the reduced alloy after it had been converted to the metallic state instantly left the high-temperature reduction zone into which the mixture to be reduced was fed. The property of changing valency and consequent variability of the oxide to be reduced was taken care of by carrying out the reaction rapidly and not allowing a gradual transition from a higher to lower oxides before ultimate reduction to the metal itself. The instantaneousness of reaction was achieved by producing an extremely localized high-temperature zone into which the mixture was directly fed.

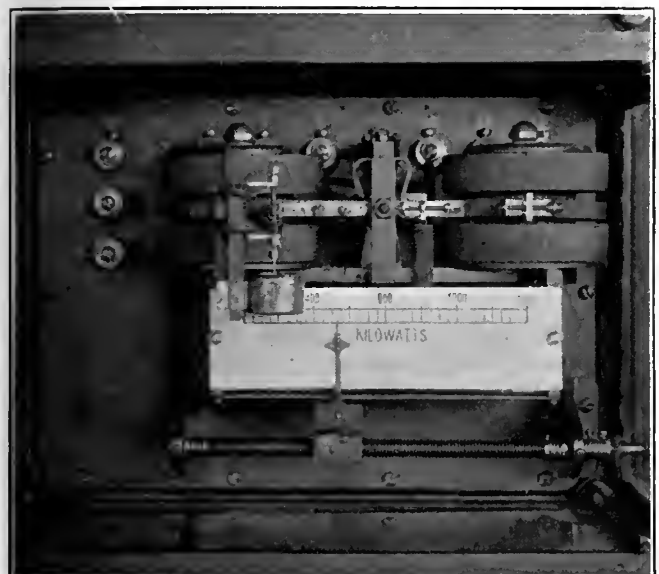
The actual experimental work was started along these lines by building a small 100-kw. two-electrode furnace. The next step consisted of a 750-kw., three-phase, 60-cycle furnace, from which the commercial operation has been standardized to a 4,000-kw., three-phase, 60-cycle unit. The voltage originally employed on the experimental furnace was 30 at the start, which was later increased to 90, 110 and 170, and finally standardized

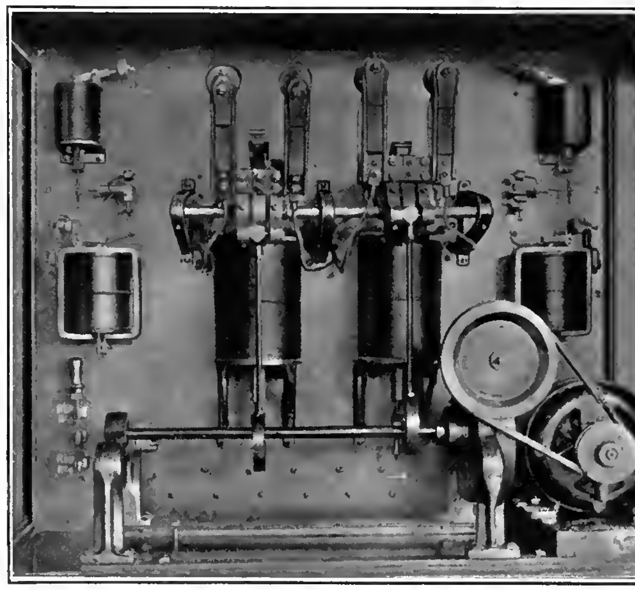
*General superintendent Vanadium Corporation of America.
†Assistant general superintendent Vanadium Corporation of America.

at 220 volts on the commercial units. It was found that the increased voltage gave more efficient results. The first experimental furnaces were of the open type, which were later supplemented by a covered unit. On account of the high temperature prevalent in the operation, the cover is water-cooled by means of coolers built in between the brick courses. The feed is charged into the furnace in a pulverized and thoroughly mixed condition by means of two automatic feeders which deliver the material between the electrodes into the hottest zone of the furnace. The feed is continuous and its rate is regulated proportionally to the energy input in the furnace. The slag-forming fluxes are selected of such a nature as to possess electric properties enabling the electrodes to dip into the slag bath so that the arc will not be exposed but submerged.

The furnace shell is made up of cast-iron segments bolted together. The lining consists of a 4-in. layer of brick all around next to the shell, followed by carbon blocks and a rammed-in mixture of coke, tar and pitch, forming a total thickness of about 44 in. Tap holes are provided for metal and slag. The over-all dimensions of the 4,000-kw. unit are approximately 16 ft. 4 in. x 12 ft. 8 in. x 7 ft. 10 in. high. The total weight of the furnace together with cover is approximately 80 tons. The three electrodes used are graphite, 12 in. in diameter. As it was desirable to interrupt the continuity of the operation as little as possible, the furnace was placed on two sets of rollers at right angles to each other, so that when the furnace needed relining it was rolled out from its position and a spare one already lined rolled in in its place, thus obviating the necessity of leaving the electrical equipment idle. This change of furnace can be effected in less than two hours and helps keep up the load factor of the installation.

For the same reason an electrode holder was designed which would curtail the time of electrode changes. The holder used works on the friction-contact principle, eliminating all bolts, nuts or other tightening devices. It consists essentially of three members—(1) the outer casing of copper, forming a hollow water-cooled ring connected to the transformer leads and having a slight taper on the inside; (2) a copper ring fitting inside the water-cooled ring and having its outside surface tapered to conform to the inside surface of the first member; (3) bronze wedges which fit between the second member and the electrode. In operation the second member is applied to the electrode by means of the wedges, this taking place on the furnace-room floor, and the electrode thus provided is lifted with the crane and simply dropped in the water-cooled first member, making a friction contact by its own weight. The advantage of this device, besides saving time, is that it obviates the necessity of loosening or tightening bolts or other devices on the top of the furnace where the working conditions are disagreeable. Further, should the holder get hot, as the water-cooled outer ring and the graphite electrode do not expand, the only material that can expand would be the second member ring and the wedges, which would produce a tighter contact, instead of a looser one, as in the case of holders of the ordinary type.





ELECTRODES CONTROLLED BY KELVIN BALANCE

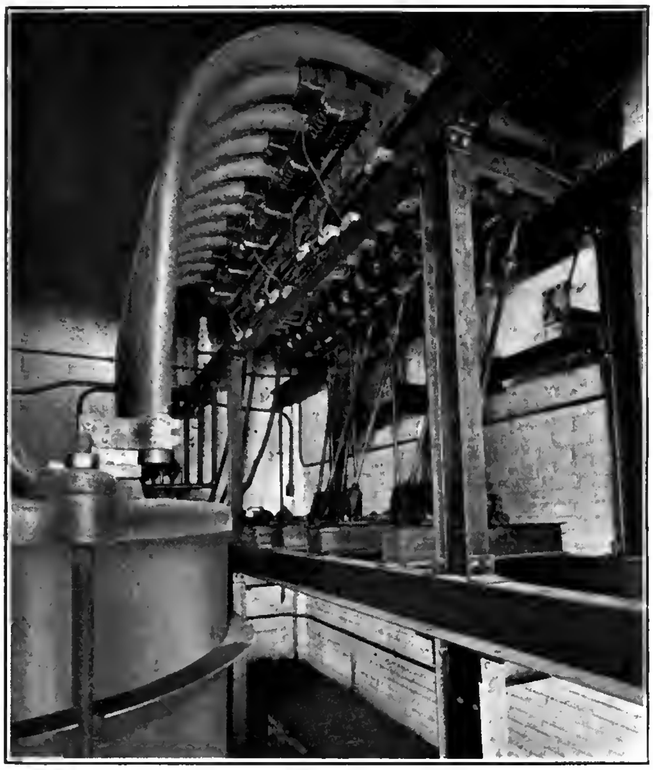
Voltage control is obtained by means of a watt balance of the Kelvin type. A watt fluctuation causes one of the contactors to close one of the auxiliary contactors, while the other auxiliary contactor continually opens and closes through the motor and cam mechanism. These devices control the electrode motors and give very accurate adjustments.

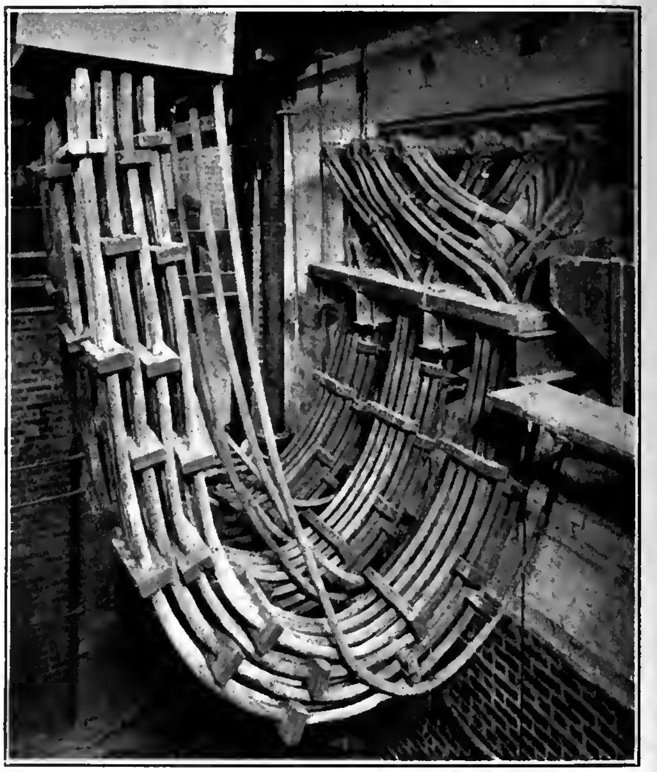
Owing to the feed being continuous and delivered immediately at the arcs under the electrodes, it is apparent that the change in electrical properties of the material at the arc will vary constantly. Combined with this, the fact that a very high temperature had to be constantly maintained to effect the reduction more or less instantaneously rendered it necessary to apply an automatic current-control system which would be capable of very close regulation, quick current rectification and high sensitiveness to very slight fluctuations. In order to keep the high temperature constant, it was considered necessary that any regulating device should not be actuated by either amperage or voltage alone but by both simultaneously effecting a true wattage regulation, thereby maintaining a truly constant energy input into the furnace. With these factors in mind the regulating mechanism described below was designed and constructed jointly by the authors.

The device consists in the main of two separate members, a watt balance and a control contact-making

mechanism. The watt balance is of the Kelvin type, consisting of a balance beam carrying a volt-actuated coil at each end balanced between two fixed ampere-actuated coils. At a predetermined wattage the beam coils are floating in balance. As soon as any watt fluctuation occurs the beam is inclined out of balance, making contact at a two-way contact point in one direction or the other, actuating from these contact points the other member of the device, namely, the contact-making mechanism operating the electrode motors. This latter mechanism consists of two opposite sets of contact arms, the one, in constant to-and-fro rocking motion, being driven through an eccentric mechanism by a motor, the other actuated by a relay magnet receiving its impulses from the watt balance and, when so actuated, meeting the rocking arms completing the neutral connected to the furnace. When the load in the furnace is balanced the magnetic pull on these relays is balanced and a contact-making switch in the watt-balance circuit is closed. Phase unbalance in the furnace load causes a corresponding disturbance in the relays, opening the circuit not affected by the disturbance because of potential differences between electrode and furnace bath, preventing movement of the electrodes unaffected by the disturbance, but causing the electrode affected to move in the direction required to restore balance, which, when reached, again closes the circuits. These magnets also function to prevent electrodes going too far into the bath or pulling out of it as the corresponding circuit opens for either direction.

In the operation of the regulating devices no direct





LEFT—TUBULAR CONSTRUCTION GIVES RIGIDITY WITH LESS TRANSMISSION LOSS FOR THE 60-CYCLE SUPPLY. RIGHT—FLEXIBLE CABLES ARE CONNECTED TO FURNACE TUBES AND THE USE OF SPACING BLOCKS PREVENTS SWAYING OF CONDUCTORS

circuit for operation of the electrode motor. The motion of the non-rocking arms is controlled by means of very fine adjustments which allow them to meet the rockers during the desired part of the arc described by them, the speed of the rockers at the same time being variable. By means of these regulations the period of contact of the arms and duration of circuit closing on the motors can be regulated to a great degree of nicety, avoiding unnecessary movement of the electrodes. Further, to facilitate quick regulation and restoration of balance in the furnace a "selective regulation" device is applied. When one of the electrodes is out of balance this device throws the other two electrodes out of the regulating circuit and holds them in their position while the unbalanced electrode finds its adjustment, thereby restoring right operating conditions in very much quicker time. The "selective regulation" device consists of magnetic relays, star-connected across phases, two magnets being present per phase for up-and-down motion of the electrodes, with a common current is used for relay or operating circuits. The current used for these purposes is that delivered to the furnace and at the voltage at which it is used in the furnace.

As the current input of the standardized units is rather high—namely, 4,000 kw. for 60-cycle current—care was taken in the layout of the secondary structure to minimize losses. Comparatively little has been published on conductors carrying heavy currents at 60-cycle frequency. The literature on skin effect has been confined chiefly to currents of high frequency, although this effect is admittedly present in conductors carrying large currents. To arrive at practical conclusions eight different systems of bus structure of combinations of flat strips and tubes were mathematically investigated. Results of these calculations offered two systems as the most promising, the one consisting of ¼-in. x 4-in. copper bars interlaced in 1, 2, 3 phase order, spaced ¼ in. apart, the other of 3-in. extra-heavy copper tubing interlaced and spaced 7 in. center to center. The flat-

strip system indicated a reactance volt drop of 0.6 per cent and a watt loss of 0.41 per cent; the tubing gave a calculated reactance volt drop of 2 per cent and a watt loss of 0.2 per cent. Both calculations were based on a current density of 800 amp. per square inch and current at 10,000 amp. to 12,000 amp. per phase. Wide differences in reactance-volt drops were found in the several systems, varying from 0.6 per cent at unity power factor to 35.5 per cent at a power factor of 60 per cent. The tubular construction was chosen because it promised less actual transmission loss than the other systems and offered a rigid and simple contrivance.

The transformer used is of the three-phase water-cooled type with a primary voltage of 22,000 and a secondary voltage of 224 at no load and 220 at full

The flexible cables are connected into the 5-in. tube in such a manner as to form the "delta" at this point, and the spacing of the flexibles is so arranged that leads carrying current of opposite sign are placed adjacent. This method is carried out throughout the entire system of cables, both with respect to leads carrying current to and from the same electrode and also with respect to adjacent leads between phases, so that the instantaneous current values are always opposite in sign. The flexibles are held in proper position and spacing throughout their length by means of spacing blocks. These blocks serve very materially to brace the cables against swaying motion without interfering with the up-and-down motion.

Results obtained by this system of heavy-duty 60-

SEPARATE CONTROL ROOM IS USED WITH PEDESTAL MOUNTING OF INSTRUMENT

load, the capacity being 4,000 kva. at 40 deg. rise and 5,000 kva. at 50 deg. rise in temperature. There are two secondary coils per phase, and leads are brought out in 1, 2, 3 phase order to the secondary terminal block. The conductors on the secondary side of the transformer, consisting of twelve 3-in. extra-heavy copper tubes, are led out through the transformer vault wall into the furnace room. A set of switches on these conductors enables "deadening" of the system extending into the furnace room, at the same time keeping the transformer "alive" for serving power for general plant operations. From these 3-in. copper tubes the current is led for each phase by means of sixteen 1,000,000-circ.mil asbestos-cored flexible copper cables into two extra-heavy copper tubes, 5 in. in diameter and 8 ft. long, running across the furnace to the electrode holder and carrying the cooling water to the holder.

cycle transmission were very gratifying, materially reducing the total impedance of the circuit. Actual tests were made at full load on the equipment, and the average of several determinations showed that the drop in potential from transformer terminal to electrode holder, the length of the leads being 50 ft., was only 3 volts, the power factor being 98 to 99.7 per cent and the total over-all efficiency, including transformer losses, 98.5 per cent. During these tests it was noticed that the highest power-factor and lowest voltage-drop readings were obtained when the electrodes were all of even length, and the worst results were obtained when one of the outside electrodes was more than 4 ft. longer than the rest. The impedance in the circuit rises on heavy overloads, the calculated reactance voltage drop reaching 17 per cent at 60 per cent power factor, thus tending to protect the equipment on overloads.

The entire control mechanism is placed outside the furnace room in a separate control room, the instruments being mounted on pedestals. The instrument equipment per furnace consists of an ammeter for each phase, a voltmeter, wattmeter, power-factor meter, frequency meter and watt-hour meter. On the first unit installed, in order to study the operation easily, all the instruments selected were of the recording type. The component of each furnace is protected automatically by overload and no-voltage relays which open oil circuit breakers. In addition, the incoming power lines, of which there are two sets, are equipped with oil switches automatically opened on overload and reverse current. Two sets of lightning arresters, one for each set of lines, afford further protection. All switches and operations of control are so equipped as to be changed instantly from automatic to hand manipulation.

The electrodes are controlled by motors provided with two speeds, the operating speed, 2½ ft. per minute, being readily alterable to a speed of 5 ft. per minute for changing electrodes or other similar purposes which often occur during the operation of furnaces of this character.

## The "Net Price Versus List and Discount" Argument

*To the Editors of the* ELECTRICAL WORLD:

The recent article in your "Manufacturing and Markets" section on "Net Prices Versus List and Discount" sets forth a line of argument that is quite familiar to the manufacturer whose product is handled through the electrical jobber. The fact that it has made no impression on the manufacturers is because the argument is fallacious. What the jobbers seem unable or unwilling to comprehend is that because they *buy* at list and discount they are not therefore compelled to *sell* at list and discount. They also seem to argue that because they buy fifty or a hundred articles at 50 per cent discount they are obliged to sell them all at 40 per cent discount, apparently trying to make it appear that it is easier to quote a separate net price on each of the fifty or one hundred articles than it is to separate the articles into, say, three groups according to the rate of turnover, quoting respectively discounts of 40, 25 and 10 per cent on the different groups as necessitated by conditions.

Let us consider further the second example mentioned in your article, namely, push-button switches. Our company does not manufacture this line of commodity, but let us suppose that the prices at which they are being sold today to the jobber are respectively 35 cents less 49 per cent for the single-pole switch and $2 less 27 per cent for the four-point switch. These figures are not far from the actual prices quoted today, and there is no doubt that the manufacturer has taken care of himself in the matter of turnover when he charges eight times as much for a four-point switch as for a single-pole switch. But what possible difference can it make to the jobber when it comes to his reselling these two devices whether he buys them at the abovementioned lists and discounts or whether he buys them respectively at $17.85 per 100 and $146 per 100, which are the "nets" of the above lists, and discounts? The single-pole switch is perhaps one of two articles which the jobber buys at 49 per cent, whereas the four-point switch is one of one hundred or more which the jobber buys at 27 per cent; but, as previously indicated, there is no obligation on the part of the jobber to sell at 15 per cent all of the articles which he buys at 27 per cent from the manufacturer.

Each jobber must determine his own turnover on every article. The manufacturer cannot do this for him. The manufacturer bases his selling price on total sales, but there are many articles which the manufacturer produces in large quantities that have a definitely localized demand. For instance, there are articles that are bought in large quantities in and around New York City and which are therefore logically resold by New York jobbers at a close price. But there is little demand and therefore a slow turnover on these devices in Dallas and San Francisco, and they should therefore be resold in those districts on a wide margin of profit for the distributor.

The real answer to this matter is that it is competition and not the manufacturer's practice that holds down the profit on electrical material. The law prohibits the jobbers from agreeing among themselves upon uniform selling prices. The jobbers would like to have the manufacturers set the resale prices, and jobber A would like to have a depth bomb set off under jobbers B, C, D, etc., whenever they deviate from the manufacturer's selling price (and incidentally select a "dud" to punish the transgressions of jobber A)—but this too is forbidden by law. The consequence is that a vast number of articles are sold on a margin of profit which is really sufficient only for a limited number of commodity items.

The question is a difficult one without doubt, but the remedy seems to be almost entirely in the hands of the jobbers themselves. Unless a considerable number of them can become accustomed to passing up orders which cannot be obtained at prices that show a profit, the remedy is probably a long way off.

## Storage-Battery Locomotives in Service

*To the Editors of the* ELECTRICAL WORLD:

In your issue of Jan. 20 you have a very interesting article on ash-disposal systems. In one respect, however, affecting storage-battery locomotives, your article was misleading. At the Ashley Street station of the Union Electric Light & Power Company two storage-battery locomotives are in service. These machines are the original machines installed in 1916. The battery has thirty cells divided in two compartments, and it gives absolutely no trouble of any kind. One battery five years old is still in service, the other one having been replaced about two months ago. A gasoline locomotive is available but does mostly standby duty during peak load when it is necessary to run two machines. Our experience has been that if the battery is kept clean and charged properly no trouble will result.

Installation, Operation, Maintenance, Test and Repair of Generation and Distribution Equipment, and Methods of Economically Utilizing Electric Service in Large Industrial Plants

## Installing Directional Relays

POWER - DIRECTIONAL relays must operate in the predetermined direction under all classes of short circuits in addition to operating at a low voltage. The most severe test is a single-phase short circuit with a high percentage of reactance. In order to insure correct operation under all conditions, the manufacturers recommend that the relays be connected in such a manner that the current in each relay will lead the voltage across the voltage coil by a certain amount when the load on the line is at unity power factor, so that when a short circuit occurs, which will generally have a high percentage of inductive reactance, a high power factor will still be obtained and each relay will be sure to operate in the right direction.

In three-phase circuits a current lead of 30 deg. is the most easily obtained, and this is a safe value to use under practically all short-circuit conditions. If the current and voltage used for operating the relays are taken off the same point of the line, it is a comparatively easy matter to select the proper current to operate with a given voltage, but often it is found more practical to have the potention and current transformers connected on opposite sides of the power transformer, which makes it more difficult to trace the correct leads for the relays.

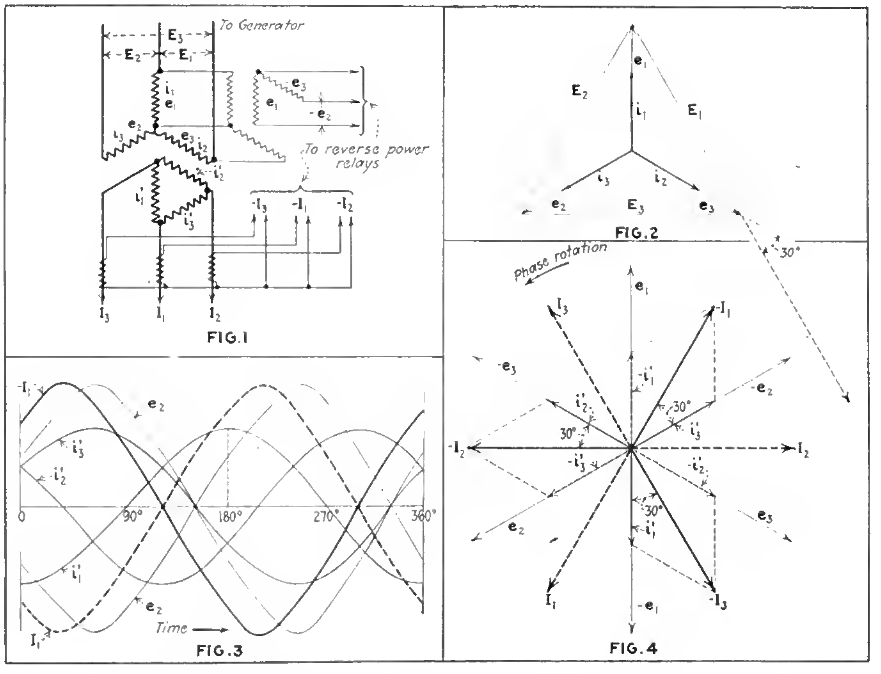
The connections of a power transformer connected star-delta, where it was desired to connect the potential transformers on the delta or low-potential side and bushing-type current transformers on the high-potential side, are shown in Fig. 1. The secondaries of the potential and current transformers were brought out for connecting to the power-directional relays to trip an oil circuit breaker in the outgoing line. The problem was to determine the proper current and voltage leads for each of the three relays.

It was, of course, necessary to know the phase rotation which was tested out and the primary power transformer leads properly marked. Fig. 2 was then drawn, giving the vector of the current and voltage at unity power factor on the primary side of the power transformer. For simplicity the arrows were drawn parallel to the respective transformer windings shown in Fig. 1. Here the voltage $e_1$, pointing vertically upward, is assumed at a maximum and is taken as the reference voltage.

The induced voltages and currents in the secondaries of all the transformers being taken as 180 deg. out of phase with the corresponding values of the primaries respectively, Fig. 4 was drawn, giving the phase position of the secondary voltages of the potential transformers and the secondary currents and voltages of the power transformer.

The phase position of the primary and secondary current in the current transformers represented in the diagrams by $I_1$, $I_2$, $I_3$ and $-I_1$, $-I_2$, $-I_3$ were also drawn. For example, it is seen from Fig. 1 that $I_1$ is made up of the vector difference of $i'_1$ and $i'_3$. The line $I_1$ $-I_1$ was thus located in Fig. 4. In the same manner the positions of $I_2$ and $I_3$ were determined. The curves of a few of the quantities shown in Fig. 4 are illustrated in Fig. 3.

It was now possible to select the pairs of leads going to each relay, $-e_1$ and $-I_3$ going to relay No. 1, $-e_2$ and $-I_1$ going to relay No. 2, and $-e_3$ and $-I_2$ going to relay No. 3. It was, of course, not necessary to trace the polarity of the leads from the transformers to the relays, as the current leads were connected in either direction and then the proper potential connection determined by means of a power-factor meter.



PROPER PHASE RELATIONS WHEN INSTALLING POWER-DIRECTIONAL RELAYS SECURED BY ANALYTICAL STUDY

## Terminal Modification That Eliminates Breakdown

ON ONE transmission system in the South considerable trouble with circuit-breaker terminals used to be encountered which has been entirely eliminated by a simple modi-

fication. The trouble was experienced only in connection with circuit-breakers that opened under overload frequently. All other circuit breakers with the same type of terminals (condenser type) gave satisfactory service. The trouble was apparently due to carbon deposit from the oil building up in the steps of the condenser bushings and eventually permitting arc-over between sections of the condenser.

Application of porcelain terminal boots filled with oil and sealed to prevent entrance of foreign matter remedied the trouble. Molded integrally into the porcelain boot is a metal base which is tapped on the inside to screw onto the lower end of the circuit-breaker terminal. To the lower side of the metal base is attached the circuit-breaker contact. The boot is filled with switch oil and a cork bushing clamped onto the top.

Seven switches the terminals of which have been so equipped failed thirty times in one year before modification, but have given no trouble attributable to the terminals since then—a period of eighteen months.

It is desirable to emphasize that this modification was not considered necessary on circuit breakers which open under overload infrequently.

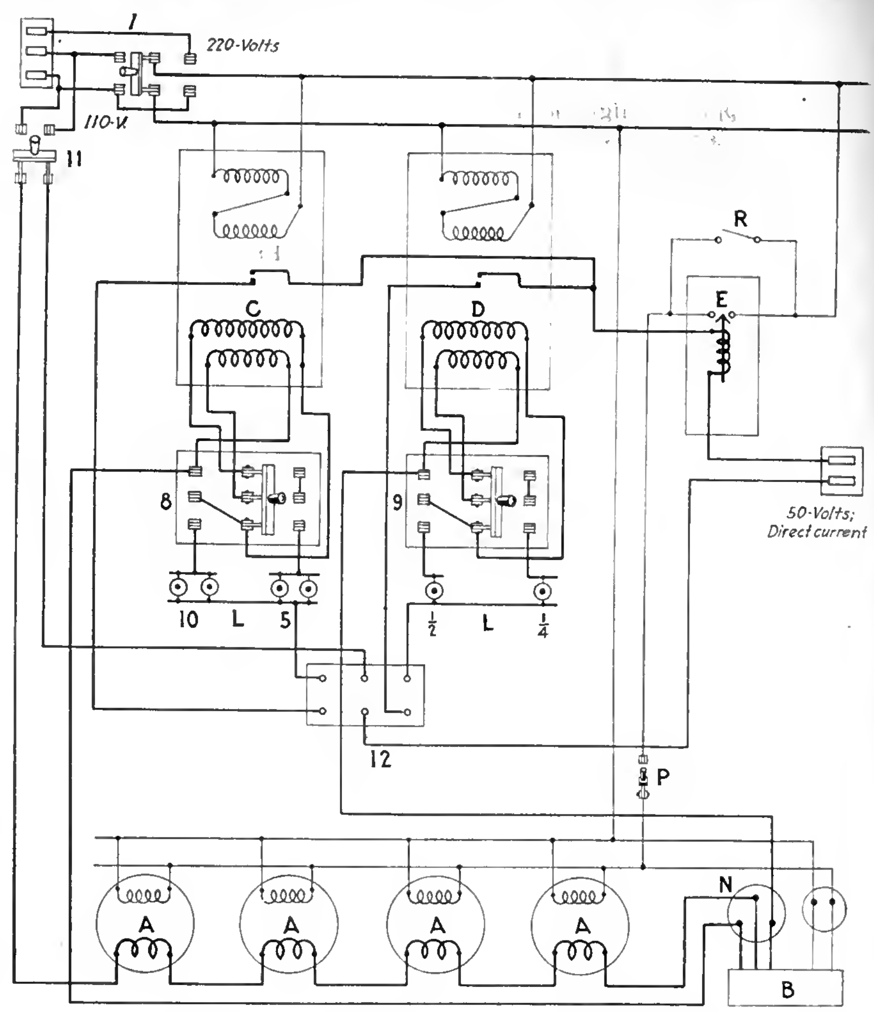
## Calibrating Five Meters Simultaneously

ALL meters, new and old, receive a pre-installation test at the laboratory of the United Illuminating Company in New Haven, Conn., and to facilitate this work and cut down time in testing smaller sizes a special board has been designed as shown in the accompanying illustrations. Five 5-amp. or 10-amp., 110-volt or 220-volt meters are tested at once. The board is equipped with spring points so that the weight of the meter under test makes the necessary circuit completions. Potential cords are snapped upon the test links with which all modern meters are provided. The equipment consists, in brief, of five vertical panels carrying the tested meters and necessary terminal blocks, a large panel carrying two master meters, switches and a contact-making relay in the center. This last receives impulses from the master meter in use at any particular time and transmits the impulses to the potential circuits of the meters under test and controlling the revolutions of the tested meters within a predetermined number of turns.

In the operation of the board, assuming that a lot of 5-110-I-14 meters are to be tested, the No. 7 potential switch (see key) is thrown for 110 volts. The master meters $C$ and $D$ are set for 110 volts, and the rotating standard meter $B$ is set. The load switches Nos. 8, 9 and 11 are thrown to the right, giving loads of 5 amp. full and ½ amp. light. The tester then throws switch No. 12 to the left, which puts full load on master meter $C$, all meters under test and standard meter $B$. After first checking the master meters with the rotating standard, the latter is removed and plug $N$ substituted to prevent any accidental short circuit affecting the standard. The master meter $C$ controls through relay $E$ the potential circuits of the meters $A$, $A$, $A$, etc., under test, so that these make three revolutions after the master meter makes four more revolutions; the $A$ meters make three revolutions again, and so on until all meters have been adjusted 100 per cent. Switch No. 12 is then thrown



TEST BOARD CONNECTIONS FOR TESTING FIVE METERS AT ONCE

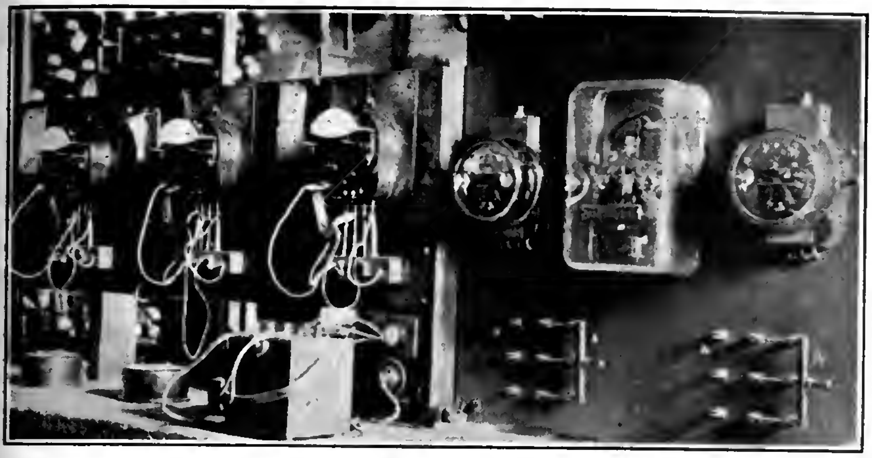
$A$—Meters under test.
$B$—Portable standard test meter used to set master meters.
$C$—Make-and-break master meter, 5 amp. to 10 amp., 110/220 volts.
$D$—Make-and-break master meter ½ amp. to ½ amp., 110/220 volts.
$E$—Relay for opening potential on meters under test.
$L$—Lamp-bank loads.
$N$—Three-pole plug receptacle for cutting in $B$, to be plugged with short-circuited plug when $B$ is not being used.
$P$—Single-pole switch for cutting out potential on $A$ and $B$.
$R$—Single-pole switch for cutting out relay, $E$.
7—Double-pole double-throw switch for potential circuit.
8—Triple-pole, double-throw switch for connecting coils of $C$ in multiple or series.
9—Triple-pole, double-throw switch for connecting coils of $D$ in multiple or series.
11—Double-pole, single-throw switch on current circuit.
12—Double-pole, double-throw switch for throwing meters under test on master meters $C$ or $D$ (located near operator).

*NOTES*

$C$—Master meter, three-wire, equipped with 5-amp. current windings arranged for series-multiple connection, and with potential windings arranged for both 110-volt and 220-volt circuits. Meter provided with special make-and-break mechanism for controlling the potential circuit of meters under test, arranged so that the potential is on such meters during three revolutions of master meter and off during four revolutions of master meter.

$D$—Master meter, three-wire similar to $C$, except the current windings, which are ½ amp., arranged for series-multiple connection. This meter makes twenty revolutions to one of meter under test.

$E$—Special relay, one end taking the impulse from whichever master meter is in use. The other end transmits the impulse to the potential circuits of meters under test.



ALL METERS OF THE UNITED ILLUMINATING COMPANY OF NEW HAVEN, CONN., RECEIVE PRE-INSTALLATION TEST

to right to apply the light load and the master meter $D$ is used.

The number of meters tested in a given time depends on how the meters average as to accuracy and what adjustments are required. With new meters needing very little adjustment we have been able to test and stock 100 to 150 and sometimes as high as 200 per day. This board can be controlled by one man, using two men to help with meter covers when rushed. As to the accuracy of the master meters $C$ and $D$, these can be set to make the standard stop on zero continuously. In fact, an error of one-tenth of 1 per cent can be adjusted. Practically all types of meters can be tested by the board, which has given complete satisfaction since its installation by the company.

R. S. HINMANN,
Meter Department.

## Instructions for Operating Boiler Accessories

WHEN dumping fires in boilers the rear dampers must be opened and the forced draft closed to prevent a flareback of the fire on account of the accumulation of gases. The ash spray should be opened to prevent excessive formation of gas in the ash pit and the burning out of the brick lining. Excessive formation of these gases may be prevented by dumping the plates in sections. Rules 8, 9 and 10 of "Detailed Instructions for Boiler-Room Force" (ELECTRICAL WORLD, Feb. 3, page 282), referring to inspection, rapidity of dumping and the handling of large clinkers, also apply to this section. The following instructions have been abstracted from the operating code of the Philadelphia Electric Company:

1. Cut off the forced draft.
2. Open the back dampers wide.
3. Stop the stoker.
4. Open the ash-spray valve.
5. Dump the plates in sections.
6. Reduce the rate of water feed, if necessary.
7. Clean the fires, being careful not to throw good coal down with ashes. If there is much coke over the top of the clinker, close the dumps before hooking out the clinker.
8. Raise the dump plates.
9. Adjust the forced and stack drafts for load.
10. Start the stoker.
11. Shut off the ash-spray valve.

Fuel economy and low stoker maintenance costs result, in a large measure, from proper operation of the clinker-crusher apparatus. Continuous operation is very necessary. Stopping the crusher while the stoker continues to push ashes to the crusher pit may cause the ash to fuse to the stoker parts of the crusher pit and burn them, while a speed higher than required may grind the ash entirely away and produce an empty crusher pit. Any burning fuel which may then fall into the crusher pit is liable to damage these parts.

1. Operate the clinker crusher continuously, according to the conditions of the fire, by adjusting the speed to keep two feet of ashes over the crusher. Do not start and stop.
2. The crusher doors should be set to the proper opening by the boiler engineer when the boiler is off and should not be changed without his knowledge or the knowledge of the water tender or boiler operator. Any change made in the opening must be reported to both the engineer and the shift superintendent.
3. The boiler engineer should make inspection every morning and evening.

In operating soot blowers on boilers, economizers and induced-draft fans the blower manifold line should be warmed up and drained of moisture which may form in it previous to blowing tubes in order that dry steam only will be blown into the tube nest. Moisture will cause soot to adhere to tube surfaces.

### SOOT BLOWERS ON BOILERS AND ECONOMIZERS

1. See that the drains on the soot-blower supply manifold are open.
2. Crack the main steam valve and blow the water out of the manifold.
3. Close the drain.
4. Open the main steam valve wide.
5. Open the soot blowers in rotation, beginning with the first pass.
6. As the unit is being blown, rotate the blower between the stops provided on the main wheel or on the hand wheel.
7. After blowing, close the main steam valve to the manifold.
8. Open the drain on the manifold and leave it open.

### SOOT BLOWERS ON INDUCED DRAFT FANS

1. The fan should be running at lowest speed when soot blowers are opened.
2. See Rules 1, 2, 3, 4 and 7, above.

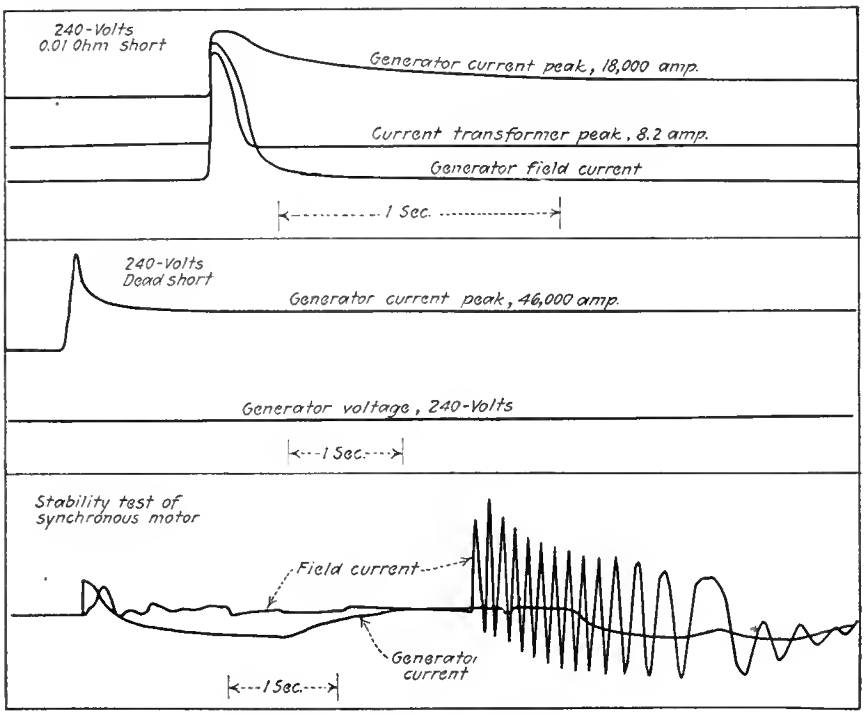
## Turbo-Generator Operation

WHEN shutting down a turbo-generator the load should be reduced to a low value to prevent a sudden rush of load from being thrown upon other machines, which might disturb the voltage of the system. The power factor should be adjusted to unity in order to reduce the amount of current passing through the machine to a minimum for the load carried, thus causing a minimum disturbance to the other machines when the main oil switch is opened. Reducing the field current to a minimum after the main switch is opened will prevent a bad arc from forming when the field circuit is opened. The successive steps in shutting down a machine follow:

1. Signal "Stand by."
2. When the "Stand by" signal is answered, reduce load to a low value.
3. Adjust the power factor to unity.
4. Signal "Stop."
5. After receiving an answer and upon noting a further decrease in the wattmeter reading, showing that the throttle has been closed on the proper machine, open the main and bus oil switches simultaneously.
6. Reduce the field current to a minimum.
7. Open the field-break switch.
8. When a bracketed exciter is used for excitation open the exciter circuit breaker.

## Favorable Test Results on Automatic Substation

A COMPLETE service restoration test with oscillograph records was made on the 1,800-kw. synchronous motor-generator set and automatic switching equipment recently installed by the Union Electric Light & Power Company of St. Louis. The test was successful in every detail of performance of the motor-generator and functioning of the automatic switching equipment. This is one of the first automatic motor-generator sets for Edison three-wire service to have performed completely a service restoration test under conditions more severe than are likely to be met in commercial operation. A noteworthy feature of this installation is that this severe test fails to disclose a necessity for making any changes whatever in the motor-generator set itself and nothing more than adjustments was needed in the automatic switching. These adjustments were made after the oscillograms shown were taken.



FEAR OF INTERRUPTION OF SERVICE ELIMINATED BY EXTENSIVE TESTS ON 1,800-KW. AUTOMATIC STATION

Top—When terminals of generator were shorted through 0.01 ohm, the current rose to 18,000 amp. Relays then operated and inserted 150 ohms in field circuit, which reduced the generator current as shown by the oscillographic record.

Center—After a dead short circuit the machine was still ready for operation.

Bottom—Stability test, consisting of loading machine, opening high-tension feeder and then closing after two and one-quarter seconds and noting effects.

The equipment comprises standard types of motor and generator. The generator has compensating pole-face windings, is of the shunt-wound type and is separately exited from a directly connected exciter. No differential or other special windings are employed.

The automatic control is equipped with a complete regulating equipment and with quick-acting generator-field control for short-circuit conditions. Means are also provided for pulling the motor back into step after a serious surge on the alternating-current supply system without having to drop the load entirely. The tests were made to determine the adequacy of these protective and operating features.

Arrangements were made to short-circuit the generator through various values of resistance, starting with 0.01 ohm and reaching a value as near zero as could be obtained with a 6-in. x ¼-in. copper bar. The short circuits were thrown on with a knife switch closed by a heavy weight. Oscillographic records were obtained of all tests, some of which are reproduced herewith.

At no time were the direct-current breakers opened until the completion of any one test. The short circuit was thrown on and allowed to remain until the load on the generator had been reduced to 125 per cent full-load amperes by the functioning of the constant-current regulator. In one of the first tests, with the terminals of the generator shorted through 0.01 ohm, the current rose to 18,000 amp. The current transformer in the main direct-current circuit had a normal ratio of 10,000-5 on alternating current, and the current in the secondary of this transformer on this test reached a value of 8.2 amp. This current trips the short-circuit-detecting relay, which functions to insert an auxiliary resistor of 150 ohms into the generator field circuit.

In another test the generator was short-circuited under extreme conditions, the circuit resistance being not more than that of 12 ft. of 6-in. x ¼-in. copper bar. The generator current reduced rapidly, following the functioning of the field control. On the short circuit the generator delivered 46,000 amp. (7,200 amp. being full load) and was in condition for continuous operation. The relatively low value of short-circuit current is obtained by the arrangement of the compensating pole-face windings. There is only a momentary spit at the generator brushes at this extreme overload. The regulator was ready to restore the generator to normal voltage when the short circuit was cleared.

In a motor stability test the generator was loaded through the test resistance to approximately 125 per cent full load. The high-tension feeder was opened at the generating station. The generator being heavily loaded, the speed dropped rapidly. After an interval of two and one-quarter seconds the feeder was reclosed. Violent oscillations occurred to the motor-field current, the highest reaching nearly three times normal. Three-quarters of a second after the alternating-current feeder was reclosed the motor-slip relay operated to reduce the generator load. The motor, thus momentarily lightly loaded, pulled quickly into synchronism.

The tests, according to the engineers of the Union Electric Light & Power Company and the Westinghouse Electric & Manufacturing Company, by whom they were made, show that with a machine of similar characteristics and a control to perform the same functions, no fear need be felt that an interruption to service will be caused.

The use of such equipments should reduce the necessity for large stand-by batteries since the major use of such batteries is to tide over heavy surges on the alternating-current system and to permit of quick restoration of service.

## Hydraulic Valve Operated by Automobile

AN EFFICIENT labor-saving device used on a large hydraulic valve which is seldom operated and which does not warrant the installation of electric drive is illustrated herewith. This is used on a 48-in. gate valve on our Lahontan power house, which is leased from the government. It consists of a U-shaped

INFREQUENTLY OPERATED VALVE DOES NOT WARRANT ELECTRIC DRIVE

piece of metal spanning the hub and held against opposite spokes on the rear wheel of the automobile. This piece is in turn fastened to the pinion-gear shaft operating the hydraulic valve.

H. SHIELDS,

Nevada Valleys Power Company,
Lovelocks, Nev.

## Generator Breakdown from Loose Laminations

HAVING had several breakdowns of certain generators about twelve years old, one Southern company made a careful study to determine the cause. These generators had been rebuilt, an operation in which the laminations had been restacked and reclamped. It was found that the old composition-metal finger plates which held the laminations together had been stressed beyond their elastic limit and had bent back, allowing the laminations to vibrate very badly.

This vibration gradually wore away the insulation on the bar-wound coils, but a short circuit did not ensue within the windings until two coils became grounded.

By replacing the old finger plates with new steel ones and clamping the laminations tightly the repetition of this trouble has been avoided so far.

## Transformer Dielectric Tests Amplified

THE standard values for insulation test voltages on distribution transformers other than small air-cooled transformers and on power transformers were amplified by the Electric Power Club at the fall meeting at Asheville, N. C., and became effective Jan. 1, 1923. The standards now cover in greater detail the requirements for high-potential test guarantees applying to transformers having single-voltage ratings above 4,500 to 50,000 inclusive. The requirements are given in the accompanying table and in the following paragraphs:

DIELECTRIC TESTS ON TRANSFORMERS

Transformers intended for Y connection shall have their test voltages determined by the line voltage and not the leg voltage.

Dielectric tests shall be made as follows: (a) Between high-voltage and low-voltage windings. (b) Between high-voltage winding and the core. (a) and (b) may be made at the same time by connecting the low-voltage winding to the core. (c) Between the low-voltage winding and the core.

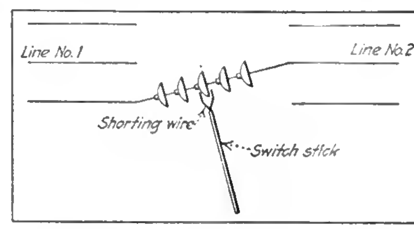
The time of application for each test shall be one minute. Measurement of voltage in making dielectric tests shall be in accordance with A. I. E. E. Sections 2358 to 2370 inclusive.

Transformer oils shall be capable of withstanding at commercial frequencies 22,000 volts between 1-in. disk terminals spaced $\frac{1}{10}$ in. apart.

FIELD EDITOR ELECTRICAL WORLD.
New York, N. Y.

## Phasing High-Voltage Lines Without Instruments

WHEN two high-voltage lines from the same source are brought together it is necessary to phase out before paralleling. This phasing may be done with a string of strain insulators and an ordinary switch stick. A string of strain insulators containing one more insulator than would be required on the line is used. The string is temporarily connected to any leg of each line. Then, with the current on, "short" out one of the center insulator units with a V-shaped wire on the end of a switch stick. If a heavy discharge is noted on "shorting" the insulator the string is connected to



STRING OF STRAIN INSULATORS USED TO PHASE OUT HIGH-TENSION LINES

phases of different polarity. If a very slight discharge or none is noted, the string is connected to the same phase. By repeating this process with each phase a definite phasing out is obtained, and the results are very positive.

When the two lines are brought together at a switch structure, it is very easy to mount the string of strain insulators below the line and connect to the "hot" wires by switch sticks.

T. W. SNELL,
General Superintendent.
Coast Valleys Gas & Electric Company,
Salinas, Cal.

TRANSFORMER DIELECTRIC TEST REQUIREMENTS FOR HIGH-POTENTIAL GUARANTEES

High-Voltage Winding to Low-Voltage Winding and Core

| Maximum High-Voltage Rating, Full Winding or Taps | Test Voltage |
|---|---|
| Below 550 | 4,000 |
| 550 to 4,500 inclusive | 10,000 |
| Above 4,500 to 50,000 inclusive | Twice the highest rated voltage* of the high-voltage winding plus 1,000 volts. |
| Above 50,000 | Twice the normal voltage† of the circuit to which the high-voltage winding is connected plus 1,000 volts. |

Low-Voltage Winding to Core

| Maximum Low-Voltage Rating, Full Winding or Taps | Test Voltage |
|---|---|
| 1,500 and below | 4,000 |
| Above 1,500 to 4,500 inclusive | 10,000 |
| Above 4,500 to 50,000 inclusive | Twice the highest rated voltage* of the low-voltage winding plus 1,000 volts. |
| Above 50,000 | Twice the normal voltage† of the circuit to which the low-voltage winding is connected plus 1,000 volts. |

*For transformers having single-voltage ratings a value 5 per cent above the rated voltage shall be used as the basis of the high-potential test.

†In systems of circuits employing transformers the normal voltage of the system or circuit is defined as the highest-rated voltage of the secondaries of transformers supplying the system or circuit. This voltage rating applies to all parts of that particular system or circuit.

## Allocating Service Cost in Rates

**Schedule Fitted to Consumer, Demand and Output Costs as Shown by a Preliminary Hypothetical Analysis— A Small-Town Example**

BY HERBERT B. DWIGHT
Electrical Engineer Colorado Public Utilities Commission, Denver, Col.

THE more one studies the annual reports of electric utilities the more apparent is the truth of the statement that, in general, rates for service are not established with due consideration to the costs of rendering the service. This is contrary to the first principles of state regulation. Numerous examples are found where one or more classes of service are paying at, or less than, the cost of production. Fair return on the investment, taxes, depreciation reserve fund allowance and other general costs, and sometimes part of the cost of production, are paid from the revenues of other classes of service. Consideration given to off-peak business, exceptional load factor, competitive service and so on cannot be made to justify these low rates to favored classes of service. There is only one answer. Every utility should make such a complete analysis of all the fixed and variable costs of rendering service that these can be fairly allocated to each class of service and then rates formulated which will make the charge to each consumer vary in direct proportion to the varying costs. Proper consideration can also be given in these rates for load factor, off-peak business, etc., by determining the value of each of these factors, present and future, in the costs of production and then making suitable allowance.

The analysis preliminary to the formation of rates may be made as exhaustive as the size of the utility and the variety of service may justify. That such analysis is worth while for even a very small utility is amply illustrated by the town of Sedgwick, situated in the extreme northeast corner of the State of Colorado. This is a municipal electric utility serving a population of about four hundred. Whether an electric utility in so small a community was warranted is beside the question. The important feature is that the analysis was made and rates established in accordance therewith which have fully proved their worth from every standpoint.

It happens that this town, in a burst of enthusiasm, contracted with some Eastern company to install a complete distribution system and a 6,600-volt transmission line 16 miles to the town of Julesburg, which operates a municipal plant. At the town limits of Julesburg wholesale power was available. After the installation was nearly completed rates were considered. Assistance of the commission was sought and an analysis was made. From the analysis it appeared that rates must be abnormally high or the town would have to support the utility in part from town funds. Rates were established in line with the results of the analysis. Every one appears to have been satisfied, and the annual reports show that the revenues and expenses have been about as predicted. This analysis has been used frequently as a pattern for others and is a distinct improvement over the old method of compiling the rates of utilities in several towns considered similar and then using the average of the compilation. This old method has been the usual one, no relation between costs and revenues being considered. It was a grand combination of faith and hope—faith that the other utilities had made a proper study of their rates and hope that the revenues would prove adequate.

Preliminary to the analysis, it was necessary to study the Sedgwick situation and from the facts developed and from the data of other similar utilities estimate the various factors needed, such as operating expenses, number of consumers in each class, the probable average consumption of each class and their participation in the system peak. The known cost of wholesale power at Julesburg was 6 cents per kilowatt-hour. The part of the investment in the combined electric and water system used for the electric service was estimated at $25,000.

It should be further noted that in electric utility operation there are investments and operating costs which wholly or in part increase and decrease in proportion to the changes in the number of consumers served. Others vary in proportion to the demand the consumers produce at the time of the system peak, and still others vary directly with the average load produced. These investments, resulting investment costs and the operating costs are allocated to the proper one of these three groups.

TABLE I—ALLOCATION OF ANNUAL INVESTMENT AND OPERATING COSTS

| | Consumer's Cost 18 Per Cent | Demand Cost, 62 Per Cent | Output Cost, 20 Per Cent | Total, 100 Per Cent |
|---|---|---|---|---|
| Investment | $4,500.00 | $15,500.00 | $5,000.00 | $25,000 00 |
| Investment costs: | | | | |
| Interest on bonds, 5 per cent | $225.00 | $775.00 | $250.00 | ....... |
| Depreciation reserve fund, 4 per cent | 180.00 | 620.00 | 200.00 | ....... |
| Profit, 3 per cent | ........ | .......... | 750.00 | ....... |
| Sub-total | $405.00 | $1,395.00 | $1,200.00 | $3,000.00 |
| Operating costs: | | | | |
| Power purchased | ....... | ....... | $3,000.00 | $3,000.00 |
| Distribution and general | $157.50 | $542.50 | $175.00 | $875.00 |
| *Sub-total | $157.50 | $542.50 | $3,175.00 | $3,875.00 |
| †Total costs | $562.50 | $1,937.50 | $4,375.00 | $6,875.00 |
| ‡Total costs exclusive of depreciation reserve fund and profit | $382.50 | $1,317.50 | $3,425.00 | $5,125.00 |

* Operating expenses only.
† Total costs, including profit, interest on bonds and depreciation reserve fund allowance.
‡ Total costs, excluding profit and depreciation reserve fund allowance.

TABLE II—ALLOCATION OF TOTAL COSTS TO CLASSES OF SERVICE

| Class of Service | *a*—Includes Depreciation Reserve Fund Allowance and Profit on Sales | | | | *b*—Exclusive of Depreciation Reserve Fund Allowance and Profit on Sales | | | | *c*—Operating Costs Only, All Other Cost Excluded | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Consumer's Cost | Demand Cost | Output Cost | Unit Charge | Consumer's Cost | Demand Cost | Output Cost | Unit Charge | Consumer's Cost | Demand Cost | Output Cost | Unit Charge |
| Residence lighting: | | | | | | | | | | | | |
| Fifty customers (63.3 per cent) | $356.06 | | | | $242.12 | | | | $99.70 | | | |
| 30 per cent participation in peak | | $581.25 | | | | $395.25 | | | | $162.75 | | |

* Per month. † Per kilowatt-hour.

After a study of the details concerned, it was determined to be fair to use 18 per cent of the totals for the consumers' cost, 62 per cent for the demand cost and 20 per cent for the output cost for the Sedgwick situation, except that all of the operating cost for wholesale power belongs in the output group.

Summaries of the analysis used in the rate study of the Sedgwick municipal electric plant are shown in the accompanying tables.

Table I shows the preliminary allocation of the investment, investment costs and operating costs to one of the three groups.

Table II shows the subsequent allocations to classes of service under three conditions—(a) that the revenues return all the costs and a small profit; (b) that they return only the interest on bonds in addition to actual operating costs, and (c) that they return only operating expenses. In the last column of each will be found the net results of these compilations. There are shown the average monthly bill to be paid by the consumers of each class and the average price that would result per kilowatt-hour used.

From Table IIa it was apparent that the rates needed and proper would be excessive. This result is proof that this investment was not justified in so small a community with its thinly scattered business. Therefore, a suitable rate schedule was formulated which would have an average effect between those shown in b and c, and the town would expect to provide part of the interest on bonds and the depreciation reserve fund out of the town funds. Such practice is not advocated, but in this case cannot be avoided. It is, moreover, apparent that, from the relative proportions of each group of the costs for a class of service, it is possible so to proportion the sliding-scale features of the rate and the minimum charge that the effect sought by the rates will be obtained. The net rates based on the allocation of costs in Table II are shown in Table III.

In conclusion, it may be noted, as shown from the annual report following a year and eight months of operation, that there has been a decided increase of the business in each class of service over that predicted at the beginning of operations. The increase for all classes amounts to 50 per cent, and the number of consumers increased from 79 to 109. This proves the suitability of the

TABLE III—RATE SCHEDULE ADOPTED

| | Cents |
|---|---|
| Residence lighting: | |
| First 3 kw.-hr. per "active room" per month, per kw.-hr. | 18 |
| Next 3 kw.-hr. per "active room" per month, per kw.-hr. | 9 |
| All over 6 kw.-hr. per "active room" per month, per kw.-hr. | 6 |
| Minimum per month, $1.50 | |
| Business lighting (optional for residence consumers): | |
| First 15 kw.-hr. per month, per kw.-hr. | 18 |
| Next 15 kw.-hr. per month, per kw.-hr | 16 |
| Next 20 kw.-hr. per month, per kw.-hr. | 14 |
| Next 50 kw.-hr. per month, per kw.-hr | 12 |
| All over 100 kw.-hr. per month, per kw.-hr. | 10 |
| Minimum per month (three lights or less), $1 50 | |
| Minimum per month (all over three lights), $2.50 | |
| Power: | |
| First 20-kw.-hr. per hp. connected per month, per kw.-hr. | 10 |
| Next 20 kw.-hr. per hp. connected per month. per kw -hr. | 9 |
| All over 40 kw.-hr. per hp. connected per month, per kw.-hr. | 8 |
| Minimum per hp. connected per month, $1 00 | |
| Municipal lighting: | |
| All energy used per month, per kw.-hr. | 9 |

TABLE IV—COMPARISON OF HYPOTHETICAL AND ACTUAL RATES, 1921

| | Actual Kilowatt-hour Sales | —Revenues Derived by Use of— Table II*b* | Table II*c* | Actual Rate Schedule |
|---|---|---|---|---|
| Residence lighting | 12,326 | $1,959.83 | $1,358.33 | $1,992.07 |
| Business lighting | 10,453 | 1,860.63 | 1,239.73 | 1,729.08 |
| Power | 26,538 | 2,759.95 | 2,319.42 | *2,574.70 |
| Street lighting | 5,181 | 611.36 | 430.54 | *466.29 |
| Total | 54,498 | $7,191 77 | $5,348.02 | $6,762.14 |
| Actual operating expenses and interest charges | | 6,822 08 | | 6,822.08 |
| Actual operating expenses only | | | 5,222.08 | |
| Excess | | $369 69 | $125.94 | |
| Deficit | | | | $59 94 |
| Percentage | | 5 42 | 2 41 | 0 88 |

* These items corrected to agree with the schedule. The town did not follow the schedule for municipal service.

rates in effect. The average rate per kilowatt-hour paid by each class of service has remained over two periods of operation almost exactly the same as predicted from the rates used. Furthermore, by applying the average rates shown in Table II to the actual twelve months' consumption per class the necessary hypothetical revenue to pay the operating expenses compared with actual operating expenses shows only 2.41 per cent error. Using Table IIb, in the same manner, a comparison of hypothetical and actual results may be made with reference to operating expenses plus interest on bonds. This comparison shows an error of 5.42 per cent, which is larger than it would be if the plant had not been built somewhat in excess of present requirements. A comparison showing the results of this study is given in Table IV.

Finally, it should be remembered that this hypothetical study and the resulting prediction as to consumption, operating expenses and the effect of the schedule were made prior to the completion of the system, and over nearly two years' operation the results have been practically as predicted.

## New York Edison Holds Sign Exhibition

The second annual electric sign exhibition under the auspices of the New York Edison Company was held during the week of Jan. 29 to Feb. 3 in the showroom of the company. This was the first of a series of specialized electrical exhibits which the company has scheduled for this year as announced in the ELECTRICAL WORLD for Jan. 13.

Twenty-six manufacturers of electric signs and sign accessories accepted the Edison company's invitation to display their wares, and at the close of the week all reported that the show had been productive of considerable new business. A partial view of the exhibit is shown here. Many urged that the show be extended into the second week, but as other things had been planned for the showroom and as the heating show is scheduled for the week of Feb. 19 it was impossible to do this.

PARTIAL VIEW OF NEW YORK SIGN SHOW

## The Wireman and His Central Station

INTERDEPENDENCE of the electrical contractor and the electric light and power company was emphasized by C. J. Russell, vice-president and general manager of the Philadelphia Electric Company, at a recent meeting of the Electrical Conference in that city. Speaking on the subject "The Wireman and His Central Station," Mr. Russell called attention to the fact that the wireman was born ahead of the central station inasmuch as long before central stations were built the wireman was very busily engaged in installing signal wiring such as bells, annunciators, etc., which was much more complex than the electric wiring of today in the ordinary house. He pointed out that in the early days it was necessary for the central station and the wiring contractors to recruit their mechanics from the then existing trades and that some of the best wiremen in central stations in those days had learned the trades of cabinetmaking, carpentry and plumbing.

Mr. Russell brought out the fact that the central-station company manufactured and distributed its product, but that it is utilized in the home and the factory entirely by means of the contractor and his wiremen and for that reason it is his central station. He also stated that during 1922 there were 32,000 old houses wired in Philadelphia and this number is expected to be exceeded during the present year. Mr. Russell suggested that the way in which the stock of the electrical central station was being sold, and with the rate of interest earned, it would not be a bad idea for the contractor and his wiremen to own some of this stock, making it still more his central station.

## What Other Companies Are Doing

**Jefferson Barracks, Mo.** — The new United States Veterans' Hospital at Jefferson Barracks, Mo., to be completed about March 1, 1923, will have a thoroughly modern electrical equipment. A 13,200-volt substation has been provided to supply energy from the Union Electric Light & Power Company of St. Louis. The total lighting load will be about 85 kw. and the connected power load will be approximately 120 hp. In addition to the light and power loads there will be installed electric cooking equipment consisting of the following: Three hotel ranges, 75 kw.; one broiler, 15 kw.; one bake oven, 25 kw.; fourteen domestic ranges (for officers' quarters and nurses), 95 kw.; eight hot plates, 4 kw.; miscellaneous other equipment, 6 kw.; total, 220 kw. The total electric load in the hospital will be approximately 400 kw.

**Illinois.**—A number of electric range demonstrations have been staged this winter by the Public Service Company of Northern Illinois in its various districts with good results. Special preparations have been made in each case. In addition to advertisements in the local papers, invitations were sent out extensively. The effect was to draw out a good attendance, a great many people driving in from small towns a dozen or more miles distant. A number of sales were made and an active "prospect" list obtained.

**Indianapolis, Ind.** — Total merchandise sales by the Interstate Public Service Company during 1922 showed an increase of $74,981, or 50.7 per cent over the sales for 1921.

# Digest of Electrical Literature

Including Brief Abstracts of and References to Important Articles Appearing in the Scientific and Engineering Press from All Parts of the World

## Hydro-Electric Development and Steam Equipment

*Control of Corrosion by Deactivation of Water.*—F. W. SPELLER.—The study of corrosion is confined particularly to corrosion under water, where the amount of oxygen present is limited to the solubility of that gas in water, and to soil corrosion, in which the ratio of moisture to available oxygen varies considerably. It includes corrosion of interior pipes, tanks, economizers, boilers and other closed water systems which form an important part of building and power-plant construction. The main factors which control the rate and distribution of corrosion of iron in water are amount of oxygen in solution, temperature, quantity and velocity of flow, quality of water and contact with electro-negative material. The author describes some of the protective coatings that have been applied to pipes and that are advantageous to prevent corrosion, giving various methods of de-aërating water and types of apparatus used to remove oxygen.—*Canadian Engineer*, Jan. 9, 1923.

*Wind-Driven Electric Power Plant.*—R. BOSSELMANN.—A feature of the suggested arrangement is the combined use of a mechanical and an electrical regulator, the former maintaining nearly uniform speed, the latter constant voltage of the driven compound-wound dynamo. Both regulators are described in detail. It is claimed that the plant will operate without any attendance, save an occasional bearing inspection.—*Elektrische Kraftbetriebe und Bahnen*, Dec. 10, 1922.

*Vapor-Refrigerating Condensers for Steam Turbines.*—F. C. EVANS.—In order to improve the economy of steam turbines by the further reduction of the back pressure, cooler condensing water must be provided or some other cooler condensing substance used. Present-day custom is to produce low temperatures artificially for various refrigerating processes. The author's investigations are along these lines, with the purpose of finding out whether it would be economical from a thermal standpoint to place cooling coils of a refrigerating system in a steam condenser to reduce back pressure on the steam turbine.—*Sibley Journal of Engineering*, December, 1922.

*Northwest Station Increasing Stoker Capacity.*—Forced-draft chain grates, replacing natural-draft stokers in the Northwest station of the Commonwealth Edison Company, Chicago, have given the increase in the steam supply necessary to meet new demands. Operation normally is at 200 per cent of rating and 300 per cent for boilers during peaks. Ordinary daily range in combustion rate is from 35 lb. to 50 lb. of coal as fired per square foot of grate per hour, with an extreme maximum up to 55 lb. A description of the new stokers is given.—*Power*, Jan. 9, 1923.

## Transmission, Substations and Distribution

*Automatic and Semi-Automatic Substations for Electric Railways.*—C. A. BUTCHER.—A general review of the subject with illustrations to show the sources of savings which result from non-manual switching forms the substance of this paper, presented before the Central Electric Railway Association, Louisville, Ky., Jan. 18. The author points out that full automatic control in general appears preferable.—*Electric Railway Journal*, Jan. 27, 1923.

*Influence of a Three-Phase Line Upon a Nearby Low-Voltage Line.*—E. NATHER.—The paper describes a mathematical and graphical method of calculating the potential induced in a low-voltage wire carried parallel to a high-voltage three-phase line, for which the author claims greater simplicity than the known purely mathematical methods.—*Elektrotechnik und Maschinenbau*, Dec. 24, 1922.

*Reinforced-Concrete Poles.*—E. MARÉCHAL.—It is suggested in this paper that reinforced-concrete poles be built from standard pieces made by series manufacture in special shops, these pieces being shipped to the places where the poles are to be erected. Here they can be assembled in a number of different pole types or even used to construct small transforming stations. Formulas are given to calculate the safe section of the concrete beams for different wire pull and tower height. Attractive appearance, long life and cheapness are among the chief advantages claimed for the towers.—*Revue Générale de l'Electricité*, Dec. 23, 1922.

## Units, Measurements and Instruments

*Short-Circuit-Proof Current Transformers.*—C. SCHRADER.—The paper describes in much constructive detail the short-circuit-proof "one-turn" or "bar-type" current instrument transformers. They are being made from 50 amp. to 3,000 amp. in a number of standard sizes, all for a secondary current of 5 amp. As the name implies, these transformers have a primary winding of only one turn, so that short-circuit forces, no matter how large they may be, can result in no destructive action. The secondary turns are arranged around an annular laminated iron core, placed concentrically around the primary bar. The unusually low values of 50, 70, 100 and 150 amp. for this type of measuring transformers are explained as follows: For the operation of relays only, where no accuracy is required, a bar type may be used for as little as 50 amp. For the operation of a single wattmeter as small a type as 200 amp., may be used with sufficient accuracy. For the operation of a watt-hour meter, or all other instruments requiring high accuracy no bar-type transformers smaller than 300 amp. to 500 amp. are recommended. These instrument transformers have been standardized with insulations up to a maximum of 300,000-volt test tension.—*Elektrotechnische Zeitschrift*, Dec. 14, 1922.

*Automatic Depth Recorder as an Aid to Navigation.*—LIEUT. S. G. LAMB.—An apparatus which determines depth soundings by utilizing the reflection of sound waves from the sea bottom is described. The principle on which the apparatus works is briefly as follows: The time interval between making a sound wave on board ship, such that the wave is transmitted to the water through the skin of the ship, and the reception of the reflected wave from the sea bottom is accurately measured and the depth is calculated from this interval, the velocity of sound in sea water in feet per second having previously been determined.—*United States Naval Institute Proceedings*, January, 1923.

## Motors and Control

*Electrical Equipment in Large Mail Terminal.*—R. G. LOCKETT.—Push-button stop and start, interlocking control and indicator lamps are features of the system of dispatching mail in the Union Station at Chicago, Ill. The author confines his discussion to a description of the electrical equipment of the conveyors, motor and control circuits and control boards.—*Railway Electrical Engineer*, January, 1923.

*Power Problems of Rolling Mills.*—A. H. DYCKERHOFF.—Oftentimes it is found that motor ratings are seemingly out of proportion with the rolling-mill duties generally practiced and that mills of apparently the same character are driven by motors of different capacity. There are several reasons for such a condition, among which are extraordinary expectations and ambitious tonnage demands and the indefiniteness of the future rolling schedules. These demands cannot be satisfied without certain sacrifices involving high first cost of motor and control, inefficiency, low power factor and inability of line and generator to deliver power. The author stresses the overpowering of mills and the resulting influence of power factor.—*Iron Age*, Jan. 4, 1923.

*Synchronizing Motors Under Full Load.*—DR. FRAENCKEL.—Synchronous motors, capable of starting under full load, have a polyphase wound rotor with collector rings and brushes leading to the starter. After starting, direct current is applied to the slip rings

and the motor changes its character from straight induction to a synchronous type. The paper contains theoretical and practical data on the exact starting conditions of this type of motor and describes what influence the position of the rotor has upon the starting conditions at the instant of applying the direct current. An automatic synchronizing device is mentioned which closes the direct-current switch at the most suitable instant. Finally an approximation method is given to calculate the smallest excitation for a given motor load. A number of oscillograms are reproduced which show a very close check between the calculated and actually observed values. — *Brown-Boveri Mitteilungen*, December, 1922.

*Individual Drive of Milling Machines.*—K. MELLER.—Several examples of modern individual motor drives for milling machines are given with the purpose of showing the great advance in the design of such drives made in the last twenty-five years. For large milling machines a multi-motor drive is advocated, so that the cutter is driven by the main motor and the feeding device by a second smaller motor. An electrically operated interlocking mechanism is then required to prevent collisions between the two independent motions. As an example, showing to what an extent such multi-motor drive can be carried out successfully, a photograph of a large milling machine with three motors for cutting and four motors for feeding is shown.—*Siemens Zeitschrift*, December, 1922.

## Illumination

*Terminal Lighting Development on the New Haven Railroad.*—G. F. JOHNSON.—Railroad yard lighting is primarily space lighting, with the following problems injected, namely, the presence of deteriorating gases, movable cars causing shadows, lack of clearance between tracks to place poles, the prevention of glare that will interfere with the operation of the trains through or near the yards and the interference of the overhead propulsion current wires. Improved illumination in several of the yards on this road is the result of much study and experiment and is briefly discussed.—*Railway Electric Engineer*, January, 1923.

## Heat Applications and Material Handling

*Coal-Handling Plant.*—M. DRUEY.—The paper describes a coal handling and conveying crane for a French mine which is unusual on account of its size. It consists of a double-portal traveling crane with a combined span of 523 ft., made up of two symmetrical halves with a span of 261 ft. each. Each half is independent of the other and has a traveling clamshell bucket of 5 tons capacity (including weight of bucket). Double rope drive is used for closing and opening the bucket. For the three motors three motors of 5½, 28 and 445 hp. are provided, all for direct current and 250 volts. A special low-speed drive permits an exact stop of the large structure at any desired point. A locking device prevents the crane with its large surface from being moved by wind. A complete wiring diagram of the crane is given.—*Bulletin Oerlikon*, November, 1922.

*Electric Steel Industry After Ten Years.*—E. F. CONE.—No marked increase in capacity and no outstanding developments marked the progress of the American electric steel industry during 1922, according to the tenth yearly review made by the author on this subject. The number of new installations registered during the last year is the smallest in the history of the industry. A tabulated review shows that the total number of installations has expanded in ten years to 407 furnaces. This table, which is included in the original article, shows where each furnace is installed, its number and size, make, and the product made.—*Iron Age*, Jan. 4, 1923.

## Traction

*Investigation of the Properties of Chilled-Iron Car Wheels.*—J. M. SNODGRASS and F. H. GULDNER.—This bulletin presents two additional phases of the investigation of the properties of chilled-iron car wheels conducted at the University of Illinois. The investigation had for its object the determination of the strain which may occur within a car wheel and the limitation of present designs with the view of improving the chilled-iron car wheel and making it more satisfactory under present and future service requirements. The first part of the bulletin contains a report of an extension of the tests previously reported in Bulletin No. 129 and discusses the strains existing in a 33-in., 840-lb. arch plate wheel when subjected to the combined effect of mounting, static load and side-thrust pressures. The remainder of the bulletin deals with a series of tests made to determine the ultimate strength of the car-wheel flange.—*Bulletin No. 134 of the Engineering Experiment Station, University of Illinois.*

*The Sydney Tramway System.*—This system is owned and operated by the New South Wales government and last year carried nearly a million passengers a day. The traffic problems include street congestion in the business district and transportation of large crowds to races and other various popular outdoor events in Sydney.—*Electric Railway Journal*, Jan. 13, 1923.

*Distribution for Direct-Current Railway Service.*—E. SORELLI.—The system consists of centralizing the distribution of electrical energy by feeding the lines with machines installed in one unique substation and supplying two different tensions. The lower tension (about 1,200 volts) is directly connected from the substation to the contact wire, and the higher one (about 1,600 volts) from the same substation to the end of each line. The distance covered by each line is about 20 miles. This would compensate the losses all along the lines and maintain the voltage practically constant. This system has had a practical application in Italy and has worked out very satisfactorily.—*Elettrotecnica*, Nov. 5, 1922.

## Telegraphy, Telephony, Radio and Signals

*Loaded Long-Distance Cables in Europe.*—P. E. ERIKSON.—The author outlines briefly some of the achievements in the field of long-distance cable telephony in Europe. When the demands of additional circuits arose several of the progressive telephone administrations in Europe turned their attention to the paper-insulated long-distance cable. The countries which first gave this question serious consideration were Great Britain, Holland, Italy, Sweden and Switzerland. The results obtained by each of these countries are described.—*Electrical Communications*, Vol. 1, No. 2.

*Standardization of Inductors at Radio Frequencies.*—The method of measuring the apparent inductance at any radio frequency of a fixed or variable inductor is described. The apparatus consists of a variable condenser, a wavemeter standardized in terms of frequency or wave length, a thermo element and galvanometer, a current square meter, several non-inductive resistors of known resistance and a source of undamped, unmodulated waves. The observations consist of the readings necessary for standardization in terms of frequency or wave length of the circuit composed of the standardized condenser, the inductor to be measured and connecting leads spaced well apart and as short as is possible without bringing the coil to within about 10 cm. of the condenser. A limited supply of this letter circular is available to persons who have actual use for.—*Letter Circular No. 76 of the Bureau of Standards.*

## Miscellaneous

*Bibliography and Patents on Electrical Insulating Material.*—In connection with the Bureau of Standards investigation of the properties of certain types of electrical insulating materials, a rather comprehensive bibliography of papers, books and periodicals has been prepared. An examination of the United States patents covering insulating materials and method of manufacture, and particularly materials of the phenolic type, has also been made. Since a considerable demand has arisen for copies of these, they have been issued in mimeographed form as Letter Circular No. 50, "Bibliography of Books and Titles of Periodicals on Properties and Uses of Insulating Materials," and Letter Circular No. 51, "Lists of the More Important United States Patents Covering the Materials and Methods of Manufacture of an Insulating Material." A copy of either will be sent on request to any persons who can show an actual need for them as long as the limited supply lasts.—*Letter Circulars Nos. 50 and 51 of the Bureau of Standards.*

## Pact Waits on Arizona

**Still Hope She Will Accept Colorado River Treaty Without Reservations—Colorado Will Follow**

TELEGRAPHIC advices from Phoenix received in Washington as the ELECTRICAL WORLD closes its forms are to the effect that Arizona will ratify the Colorado River compact without nullifying reservations. Sentiment has changed decidedly during the last few days as the pressure of public opinion has become more and more felt, and it seems certain that a majority of the members of the Arizona Senate will vote for ratification rather than assume responsibility for the defeat of the ratification bill now before them, which would have the effect of delaying indefinitely any important development of the river. It is also stated that the Senate will eliminate the three reservations which the House committee has proposed, even if the House should pass the bill with those reservations intact.

Since it is believed very generally that Colorado, the only other state of the seven affected which has not ratified, will act quickly once it is assured that Arizona will ratify, there still is a chance for the sitting Congress at Washington to ratify the compact and put it into effect.

### The Proposed Reservations

The reservations proposed by the committee of the Arizona House of Representatives provide for the payment of $5 per horsepower-year on all power generated in Arizona, that Mexico's rights to water be restricted to 2,000,000 acre-feet, and that the Gila River be eliminated from consideration. It is very evident that any ratification with reservations is tantamount to no ratification. It is contended by those interested in the development of the river that no effort should be made in this indirect manner to interfere with ratification. It is believed that the reservations themselves are the outcome of misunderstanding. The state can place the $5 royalty tax at any time, and it is apparent that it should be carried in a separate bill; nor is it within the jurisdiction of a state to suggest what the federal government shall do in a matter of international relationships, while to eliminate the Gila is entirely contrary to the spirit of the compact—Colorado would have just as much right to adopt a reservation eliminating the Grand.

The opposition in Arizona to ratification has come from three groups. The principal opposition has been from those misunderstanding the results that the adoption of the compact would bring. It is this group that now has been largely won over to ratification. A second group apparently is actuated by selfish political motives. The third group is that which favors municipal ownership.

## Electricity, Again Blamed for Fire, Again Acquitted

Twenty-seven inmates and attendants lost their lives in a fire which broke out last Sunday in an asylum for the insane on Ward's Island, in the East River at New York City, and Monday's newspapers attributed the blame to "uninsulated wires." Wednesday morning's papers, however, contained the tardy assertion that the official investigators had "united in eliminating electrical wiring as the cause of the fire," which was the second in two weeks. The chief electrician testified that all the lamps in use in the building were burning after the fire started.

## President Harding Approves Reorganization Plan

The joint congressional committee on reorganization of the government departments has received from President Harding an outline of the reorganization plan recommended by the President and the Cabinet. The outstanding recommendations are as follows:

1. The co-ordination of the military and naval establishments under a single Cabinet officer as the Department of National Defense.
2. The transfer of all non-military functions from the War and Navy Departments to civilian departments, chiefly Interior and Commerce.
3. The elimination of all non-fiscal functions from the Treasury Department.
4. The establishment of one new department, the Department of Education and Welfare.
5. The change of the name of the Post Office Department to Department of Communications.
6. The attachment to the several departments of all independent establishments except those which perform quasi-judiciai functions or act as service agencies for all departments.

These general proposals are followed by a detailed list of suggested changes and transfers in the respective departments as now constituted. It is highly improbable that any bill founded on these recommendations can be reported to the present Congress, which expires on March 4.

## Three Utility Bills Now In

**The New York Administration Aims to Abolish the Present Commission and Aid Public Ownership**

THREE bills embodying the plans of the state administration for utility control were introduced into the New York Legislature on Monday of this week. One of them legislates the present Public Service Commission, composed of five members with terms of ten years, out of office and creates a new commission, composed of three members to serve for six years. This measure abolishes the law passed during Governor Miller's administration whereby the commission was authorized to increase or reduce a rate of fare or charge by a public utility fixed by franchise agreement. It also strikes out the authority of the commission to establish temporary rates pending a hearing requested by a utility.

There is some question as to whether the object of this measure, to restore former contract rates, has been accomplished, since the legislation of 1921, by implication, abrogated all existing contracts and repealed all special and general laws and since the measure now presented has failed specifically to mention such abrogated contracts or to re-enact any statute that might have been so repealed.

### Municipal Ownership Favored

Under one of the two other bills, an amendment to the general city law, all municipalities throughout the state are endowed with the broadest powers to "own, establish, construct, acquire and operate" public utilites of all kinds. The Board of Estimate in New York City and the common councils of other cities, with the consent of the Mayor, under the terms of this bill would determine the policy of their respective municipalities. There is no provision for a popular referendum.

Existing utilities "or any part thereof" may be acquired by condemnation and the necessary expenditure involved met either by taxation or through a bond issue. The bill does not affect transit facilities in New York City already provided for in Mayor Hylan's transportation bill, but it relates to all other classes of public utilities in the city.

The third bill eliminates from the Public Service Commission law all references to the New York City Transit Commission, which is to be abolished, and makes the law conform in other respects to the New York City transportation bill now pending.

## Lessons of Eagle Rock Fire

**Need for Care in Placing 60,000-Volt, Oil-Filled Lightning Arresters—How Service Was Restored**

THE disastrous fire which occurred at the Eagle Rock substation of the Southern California Edison Company on the evening of Jan. 8 owing to the explosion of a 60,000-volt oil-filled lightning arrester indicates that considerable care must be used in installing such arresters. It is probable that if in this case the arresters of this type had been placed exterior to the substation or if arresters which contained no oil had been used much of the damage would have been avoided.

The fire started at 9 o'clock in the evening, when a set of 60,000-volt aluminum-cell lightning arresters blew up. It is thought that there was a short circuit on one of the lines, but it is not known whether there was an external short or whether the failure of the arrester itself was the short. When the arrester blew up it spilled burning oil in all directions throughout the 60,000-volt lightning-arrester room. This caused the other arresters to become overheated, and they in turn boiled their oil out, which resulted in a more intense fire. It is also probable that some of the arrester tanks overturned. The fire burned out the windows between the 60,000-volt arrester room and the riser wells of the transformers and lines, and the smoke from this burning oil went to the fourth and fifth floors of the substation building, collected around the 150,000-volt bus and burned under the ceilings of these floors.

The 150,000-volt arresters were in a gallery above the 60,000-volt arresters. There were windows between this gallery and the riser wells as well as behind the 150,000-volt arresters. These windows burned out, and the heat, which was very intense, set the arresters on fire or caused them to blow up. The two 150,000-volt buses were damaged to such an extent that it was necessary to replace most of the porcelain insulators, porcelain disconnecting switch supports and parts of the bushings of the 150,000-volt switches. None of the major equipment in the substation, such as the transformers and synchronous condensers, was damaged. The control board was also uninjured. The transmission line to the substation was left in first-class condition. The section of damaged 150,000-volt bus between the transmission line and the transformers was the chief loss. The total damage will probably not exceed $100,000, which is considerably less than the half million first reported.

### How Service Was Restored

To restore service the Big Creek power-house transformer connections on the high-tension side were changed from 150,000 volts Y, with grounded neutral, to approximately 80,000 volts delta. At Eagle Rock the transmission line was disconnected from the bus, a few temporary poles were set and Big Creek was fed directly into the 60,000-volt system just outside of Eagle Rock substation, thus supplying Southern California. The only crippling of service was on the 15,000-volt railway supply at the time of the morning peak on the next day, and this condition was remedied within a few hours.

It was found that "foamite" was of considerable value in fighting an oil fire, and steps are being taken to install such fire-fighting equipment in all of the principal stations on the system. At present the station is operating under normal conditions on the Big Creek line, with one 150,000-volt bus at Eagle Rock in first-class condition. It was necessary to use the delta, 80,000-volt connection at Big Creek for only about five days before Eagle Rock was sufficiently repaired to permit of 150,000-volt grounded Y operation on the Big Creek line. Fortunately none of the 220,000-volt auto-transformers or other 220,000-volt equipment in the process of installation at Eagle Rock was damaged.

## Public Relations Main Theme at Albuquerque Meeting

Better public relations was the theme that dominated the ninth annual convention of the New Mexico Electrical Association, held on Feb. 12 and 13. While there were a large number of papers and addresses dealing with the technical and business sides of the public service industry, it was noticeable that even these were tinged with one thing or another concerning the building of public good will.

The convention was held in Albuquerque and the attendance was the largest in the history of the association. The manufacturers, jobbers and dealers, as well as the central-station companies, were largely represented, delegates coming from as far east as Chicago, as far south as El Paso, as far west as San Francisco and as far north as Denver. As a result of the discussions growing out of the various addresses and papers on public relations, this phase of the public utility industry will receive the attention of all of the universities in New Mexico.

Those who delivered addresses or read papers were: B. C. J. Wheatlake, General Electric Company, Denver; J. E. Moorhead, Mountain States Telephone & Telegraph Company, Denver; C. A. Winder, Southwest General Electric Company, El Paso; Dr. John D. Clark, State University of New Mexico; George E. Lewis, executive manager Rocky Mountain Committee on Public Utility Information, Denver; Prof. R. W. Goddard, State College of New Mexico; J. F. Dostal, Colorado Springs Light, Heat & Power Company, and M. Nash, an electrical contractor of Albuquerque.

E. A. Bradner of the Las Vegas Light & Power Company, Las Vegas, was elected president of the association, to succeed D. E. Bent of the Tucumcari Light & Power Company. Charles E. Twogood of the Albuquerque Light & Power Company was re-elected secretary.

## News from the Capital

**Radio Bill Doomed in Senate—Ford Bill Not Reported Out—High Dam License Waits on Minnesota**

FROM the Washington bureau of the ELECTRICAL WORLD news comes that the radio bill is dead. The Senate committee on interstate commerce has decided definitely to take no action on the measure which already has passed the House of Representatives. Senator Underwood, the Democratic leader, takes the position that the bill is too important and too far-reaching to be rushed through in the closing days of Congress, when it is impossible to scrutinize it carefully and to conduct the public hearings which he deems necessary.

The failure of this legislation, along with the legal decision which has overthrown the present methods of restraint, leaves radio communication practically uncontrolled. Secretary Hoover says that he will search for authority to follow a temporary policy, but he is doubtful whether those concerned would undertake the necessary new instrumentation which would have to accompany a change of wave lengths, when there could be no guarantee as to the permanency of the new plan.

### Ford Bill Not Reported

By a vote of six to thirteen the House rules committee refused on Monday to report out a resolution giving Henry Ford's offer for Muscle Shoals right of way in the House. This precludes consideration of Muscle Shoals legislation at this session unless a majority of the House votes to override the rules committee.

### Status of High Dam

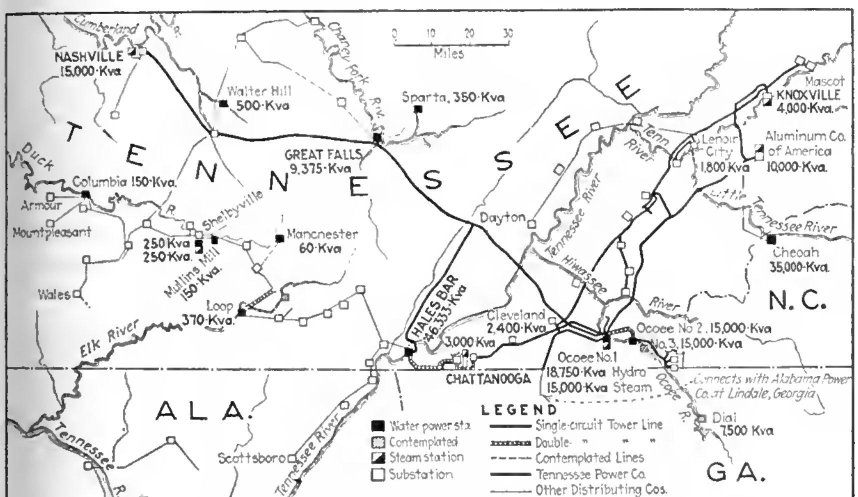
Advices received at Washington from St. Paul are to the effect that the Minnesota Legislature is not likely to adopt the bill authorizing the Municipal Electrical Corporation or the city of Minneapolis, or both, to issue bonds to put in the power project at the High Dam on the Mississippi. Apparently a majority of the members of the Legislature feel that the placing of a power business which would amount to $1,000,000 a year at the disposition of a city council which changes each two years would not make for economical operation and would result in costly power.

The Federal Power Commission will not act in this matter until the Legislature takes definite action or adjourns without having taken action. It will then determine promptly, it is believed, who shall have the license. It will apparently be a question of determining whether it shall go to the Northern States Power Company or to Henry Ford, and there is a very generally held opinion that the license will go to the Northern States Power Company, as the water-power act places the use of power sites for public utility purposes above their use for private industries and this policy has won the favor of the Federal Power Commission in previous cases of similar character.

# Electrical Progress in Tennessee

### Expansion Program of Tennessee Electric Power Company Includes Additions at Nashville, Chattanooga, Great Falls and Other Places—Selecting Site for New Steam Plant

LOAD is increasing so rapidly on the system of the Tennessee Electric Power Company that it has already ordered a 12,500-kva. turbo-generator for the steam plant at Nashville to bring its rating up to 27,500 kva. and is contemplating other additions. Among the company's problems are the best method of increasing the 10,000-kva. hydro-electric development at Great Falls, on the Chaney Fork River, and the best location for a new steam station probably of 15,000 kva. to 20,000 kva. rating. The installation of switches are to be installed during February or March at Parksville, and some of the high-tension switches are being modified to give better rupturing performance. Among the chief changes being considered are stronger tanks, heads and tie rods on some switches, mufflers and explosion chambers on others and new bushings on still others. Since some of the switches are not adapted to bushing-type current transformers, an oil-immersed shunt has been devised for activating the tripping circuit.



TENNESSEE SYSTEMS MERGED INTO THE TENNESSEE ELECTRIC POWER COMPANY

a 7,500-kva. synchronous condenser at Chattanooga to improve voltage regulation is another project. A 120,000-volt circuit will be built from Cleveland to Knoxville, giving duplicate service at 120 kw. At Great Falls there is the opportunity of increasing the head 30 ft. to 35 ft. and thereby improving the chance to add a 15,000-kva. waterwheel generator, making a total of 25,000 kva.

Three sites for a steam plant are being considered, near Hales Bar, or at Chattanooga on the Tennessee River, or at Knoxville. The most advantageous point would be at Hales Bar, because plenty of condensing water would be available, coal could be transported by barge, and besides the plant would back up the Hales Bar hydro-electric plant during the dry season and during high backwater. Furthermore, no new transmission line would be needed.

Other water-power sites remain to be developed on the Ocoee River, but from an economical standpoint they remain in the future. Additional power facilities are also expected after the completion of the 110,000-volt line which the Georgia Railway & Power Company contemplates from Lindale, Ga., to the Tennessee-Georgia state line to connect with a line to Chattanooga.

Switching facilities are being improved. Entirely new low-tension

About eighty thousand insulators are being replaced by others of the same make but of a more modern type. To determine which shall be changed the "buzz stick" method is being used and the insulators are being changed with the circuits "alive."

Between Cleveland and Copper Hill, where no telephone lines exist, carrier-current communication will be utilized.

## European Engineers Take Note of Joint Committee

At a meeting of the executive committee of the Joint Committee for Business Development held in New York on Feb. 15 it was announced that requests had been received from nearly thirty cities asking assistance in the formation of local leagues or clubs.

Messrs. Lane, Marshall and Goodwin were appointed a committee to prepare a display for the Joint Committee at the N. E. L. A. convention in June.

William L. Goodwin of the Society for Electrical Development reported that the society's first monograph, "Building Residence Lighting Business," would be completed about the middle of March. "Useful Information for Architects and Builders," he said, will be ready in April, and other booklets are being prepared. These include "Customers Versus Population," "Advertising Service for Electric Homes," and "Organizing and Conducting an Electric League."

A. K. Baylor, chairman of the wiring department, reported that he had prepared a paper on wiring for the General Engineering & Management Corporation and that it had been sent to all the officers of that organization. The booklet being prepared by the heating and melting department, of which C. K. Nichols is chairman, will soon be ready.

S. E. Doane of the National Lamp Works of the General Electric Company spoke of the conditions in the European electrical industry which he studied during his recent trip abroad. He said that he had heard of the work of the Joint Committee as far east as Hungary, and that the European engineers were amazed at what had been accomplished in this country. He predicted that before long foreign countries will send electrical missions here to study our methods.

## Alabama Utilities Must Open Their Books

Public utilities in Alabama must open their books to the Public Service Commission of the state at any time that body requires, under a bill just signed by the Governor. Any person appearing for the public in a valuation case may apply for a rehearing and appeal to the courts from any decision of the commission. Heretofore only the company could apply for a rehearing or appeal from the commission's ruling.

The law is a result of the contention by the Alabama Power Company and the Mobile Gas Company that the commission had no right to grant a rehearing after a tentative valuation had been fixed. Both companies declined to submit books on the ground that no cases requiring such inspection were pending.

## Los Angeles A. I. E. E. Hears About Ceramics

Before the February meeting of the Los Angeles Section of the American Institute of Electrical Engineers, Frank H. Riddle, president of the American Ceramic Society, and Dr. J. A. Jeffery, president of the Champion Porcelain Company, read papers, Mr. Riddle dealing entirely with ceramic development of porcelain insulators and Dr. Jeffery discussing modern methods of firing high-voltage porcelain. Both speakers referred to the discovery of silaumite, which Dr. Jeffery stated eventually would replace the clay now imported from England in forming the principal body for porcelain. Silaumite, he said, is mined at the present time exclusively in California and it is found within 50 miles of Bishop. So far as known, there is no other place in the United States where this mineral is to be found. At least this is the only commercial deposit of which there is now any knowl-

edge. Mr. Riddle said his companies had 500,000 lb. of silaumite in Detroit at the present time for porcelain making. This mineral, though discovered only two years ago, is revolutionizing porcelain for long-distance transmission purposes, he declared.

"As mined at present," said Mr. Riddle, "many difficulties are met with. It is brought to the railroad by burros and then shipped to Detroit. The present supply is adequate and there is a strong possibility in the not distant future of building a plant of large proportions on the Pacific Coast. Before any such step is undertaken, however, more experimental work must be prosecuted. We are still developing an electrical fire kiln to carry loads twenty-four hours."

Both speakers asserted that the Pacific Coast buys in one year in insulators approximately what the rest of the United States buys in two years.

# To Improve Lighting of Post Offices

### Expert Investigation Carried Out Under Federal Direction Brings Recommendations for Standard System All Over Country Insuring 10 Foot-Candles on Working Plane

ESTABLISHMENT of a standard system of lighting in all post offices has been strongly recommended in a report just submitted to the Post Office Department by the Office of Industrial Hygiene and Sanitation of the United States Public Health Service. This report, the result of an elaborate survey conducted at the special request of Postmaster-General Work, maintains that millions of dollars will be saved through increased speed in the work of postal employees provided that a complete change is effected in the illumination of workrooms of post offices throughout the country.

Virtually all the work performed in post offices with the exception of that of laborers depends primarily upon the use of the eyes, making the question of illumination of paramount importance in decreasing or increasing its rapidity and accuracy. Conducting a thorough and technical study of lighting over a long period of time at two representative post offices, one modern and the other of the old type, the experts observed almost five thousand postal workers employed constantly in handling the mails both under artificial and natural light.

They found that illumination in many post offices was low in intensity and unsatisfactory in quality. In some instances it fell below the requirements provided by the state code of laws and below the artificial light furnished employees in private industries doing similar work. A study of the relationship between the volume of illumination and the strain on the eyes of workers revealed the fact that there were more eye defects among employees working under the average illumination of 2 to 3 foot-candles in the old post office than under the 3 to 4 foot-candles in the new post office. Sorting and separating mail in the basements of post office buildings was especially discountenanced except in extreme emergencies.

#### Speed Increases 4.4 per Cent

In the speed and accuracy tests it was found that for the letter separators there was an average increase in speed, or decrease in the times of separation, of at least 4.4 per cent when going from 3.6 to 8 foot-candles. Assuming that the same relative increase of speed would prevail in all the divisions of the post office where these tests were made under the same relative increase in illumination, an annual net saving, after deducting increased cost for lamps and energy, of about $109,000 was indicated in this post office alone.

#### Intensity of 10 Foot-Candles Needed

The investigations recommended that there should be installed in the general workrooms and offices systems of totally inclosing units of the diffusing or light-directing type, giving a general intensity when first installed of 10 foot-candles everywhere on a horizontal working plane 45 in. above the floor. All local lighting should be done away with.

The lighting unit to be installed in the general workrooms of the post office should be of such quality of glass and of such shape and size that its surface brightness at any point would not exceed 2.5 cp. per square inch when used with an incandescent lamp or other source of light emitting 3,100 lumens. This unit should have an output of at least 80 per cent of that of the clear lamp and a spherical distribution of its candlepower such that at least 8 per cent of the light emitted by the clear lamp would be emitted by the unit through the zone from 0 deg. to 30 deg., at least 28 per cent from 0 deg. to 60 deg., at least 48 per cent from 0 deg. to 90 deg., and at least 25 per cent from 90 deg, to 180 deg.

The lighting unit for the offices of the post office should be of such quality of glass and of such shape and size that its surface brightness at any point would not exceed 2 cp. per square inch when used with an incandescent lamp or other source of light emitting 3,100 lumens. This unit should have an output of at least 80 per cent of that of the clear lamp and a spherical distribution of its candlepower such that at least 8 per cent of the light emitted by the clear lamp would be emitted by the unit through the zone from 0 deg. to 30 deg., at least 23 per cent from 0 deg. to 60 deg., at least 43 per cent from 0 deg. to 90 deg., and at least 35 per cent from 90 deg. to 180 deg.

Both the units for the general workrooms and the offices should be such in number and so spaced that the brightness of the units measured in lumens per square foot would not be more than one hundred times as great as the intensity of the illumination, measured in foot-candles, produced by them on a horizontal plane 45 in. above the floor.

Recommendations on the care of the lighting system and a disquisition on modern methods of illumination are included in the report.

## Solidarity Theme of Pacific Coast Supply Jobbers

The quarterly meeting of the Pacific Division of the Electrical Supply Jobbers' Association, held at Del Monte, Cal., Feb. 8-10, was the largest which the records of the association show. The sessions were in charge of Chairman C. E. Wiggin, and, besides the jobbers, an unusually large registration of manufacturers and representatives of other electrical interests took place.

The open meeting of Feb. 10 was in charge of E. O. Shreve, San Francisco manager of the General Electric Company. R. A. Balzari, Westinghouse Electric & Manufacturing Company, spoke on "Business Courtesy," and W. R. Alberger, vice-president San Francisco-Oakland Terminal Railways, dealt with the problems of electric railway business.

The principal discussion of the meeting centered around a chart, designed and presented by E. O. Shreve, describing a proposed co-ordination of the different electrical clubs, leagues and societies to promote a greater solidarity of interest in the mutual problems of public utilities, with particular reference to their bearing upon the electrical industry.

## Oklahoma Gas & Electric Is Friend in Need

Fire on Saturday afternoon, Feb. 10, completely destroyed the electric light plant of the Minnesota Light & Power Company at Cushing, Okla. As soon as the seriousness of the blaze was seen the Mayor of Cushing called up J. F. Owens, vice-president and general manager of the Oklahoma Gas & Electric Company, at Oklahoma City, and asked for aid in restoring service. Response was instant, and superintendents and crews of the Oklahoma Gas & Electric Company were rushed to Cushing from various division headquarters. Emergency lines were strung to the circuit of the Shaffer Oil & Refining Company, just outside of Cushing, which is served from the Oklahoma company's transmission line. As a result, Cushing suffered little inconvenience from the loss of the plant. Storekeepers were able to transact their usual Saturday night business, and even residential districts were in part supplied with lighting.

Much appreciation of this prompt assistance has been expressed in Cushing, whose people would without it have probably had to wait months for the resumption of electrical service.

## University of Minnesota's Claim on High Dam

The claim of the University of Minnesota to 15 per cent of all power that may be developed at the High Dam, built by the federal government across the Mississippi between Minneapolis and St. Paul, has been already referred to in the Electrical World. This claim is supported by a resolution passed by the regents of the university at the instance of Governor Preus of that state. The Governor's stand is based on the agreement entered into when the dam was begun. A corporation of three members was then formed—the Mayors of Minneapolis and St. Paul and the chairman of the board of regents of the University of Minnesota. The general understanding was that the three corporations, two municipal and one educational, were entitled to share the power equally.

The city of St. Paul favors turning the power over to Ford. Minneapolis business men also favor that policy, although the city administration does not. Both groups ignored the probable attitude of the University of Minnesota until Governor Preus came forward with the resolution showing that had it not been for university expert advice the dam never would have been built at a point making the development of water power available. Furthermore, the resolution says, the University of Minnesota is co-operating with the federal government in many experiments requiring power and is the only state university situated close to power that is still under the government's control.

The power available at the high dam will range from 2,500 kw. to 10,000 kw. according to the time of year and has been estimated by electrical engineers at 18,000,000 kw.-hr. a year. Supporters of the Ford plan have maintained that the university could not use more than 1 per cent of the power and that Ford plans erection of a large electrical experiment plant at the dam and is willing to give faculty and students the use of this plant.

The university regents have authorized architects to go ahead with plans for a new electrical engineering building to cost $300,000, and it is planned to begin work in the spring. The university is also just completing a large and finely equipped mines experiment and ore-testing station, and much electrical power will be required for its operation.

## Million-Volt Laboratory to Be Finished by March

Construction work on the high-voltage laboratory at the California Institute of Technology is progressing rapidly, and it is expected that the building will be completed by the first of March. The laboratory will be used jointly by the institute and the Southern California Edison Company.

In the laboratory will be installed a million-volt transformer to permit electrical engineers to obtain high voltages for experimental purposes. The Edison company engineers plan to conduct high-voltage tests in connection with their work in transmission. Dr. Robert A. Millikan will use the high voltage in his work on the constitution of atoms.

The million-volt transformer is one designed by Prof. R. W. Sorensen of the institute and will be in four units. In addition to the transformer there will be Poulsen arc equipment, which will be used to obtain high voltages at high frequencies.

## New U. S. Army Dredges to Be Completely Electrified

An illustration of the growing tendency to use electricity on shipboard is provided by the four hopper dredges designed by the United States Engineer Corps and being built by the Sun Shipbuilding Company, Chester, Pa. Electricity will propel these ships and steer them, operate the dredging pumps and all auxiliary machinery, supply heat in winter, cool breezes in summer and ventilation at all times, furnish hot water and do the cooking. There will be no fires of any kind.

The main engines of each dredge will be three 1,000-boiler-hp. McIntosh & Seymour Diesel engines, each of which will be directly connected to a 700-kw., 500-volt direct-current generator of 150 r.p.m. These generators will furnish the power for operating the propellers and the dredging pump. Each dredge is to be propelled by twin screws, and each propeller is to be directly connected to an 800-hp., 480-volt direct-current motor of the double-armature type. The speed of these motors can be varied from 90 to 110 r.p.m. The main dredge pump is to be driven by a 750-hp., 480-volt direct-current motor which has a speed variation of from 135 to 160 r.p.m. The windings of both generators and motors will be impregnated with moisture-resisting compounds and inclosed by protecting covers. Forced ventilation will be provided by small motor-driven blowers. Among the motor-driven auxiliary machines on each dredge are twenty-five auxiliary pumps, two air compressors, the steering gear, a windlass, two capstans, two winches, two hopper-door openers, the ladder hoist and the refrigerating machine. The control of almost all of these motors is to be of the automatic type.

Included in the electrical equipment of each dredge are to be eighty-eight electric room heaters, ranging from 1,000 watts to 5,000 watts each in capacity, three 5,000-watt water heaters for each hot-water boiler, twenty-three electric fans and two electric ranges of 22-kw. rating each. The auxiliaries will be supplied with current from two auxiliary Diesel-engine-driven 150-kw., 250-volt generators and also from a 150-hp. motor-generator set which can be supplied with power from the generator operating the dredge-pump motor.

All of the electrical equipment on these dredges is being supplied by the Westinghouse Electric & Manufacturing Company.

## N. E. L. A. Appoints Convention Committees

Announcement has been made at the headquarters of the National Electric Light Association of the appointment of the following chairmen of sub-committees in connection with the annual convention in New York City next June: Inspection trips, Philip Torchio; preparation, printing and delivery of entertainment programs, Clarence L. Law; golf, H. M. Edwards; theaters, William J. Clark; local transportation, Col. J. Stillwell. Godfrey N. Atkins will be master of transportation. The hotel committee, it is reported, has its work well in hand.

## Northern States Power Is Spending $5,000,000

As part of its recently announced eighty-million-dollar ten-year hydro and steam power construction and development plan, the Northern States Power Company will soon start work on a new terminal substation in Minneapolis to serve the downtown and northwestern sections of that city. The new substation, together with connecting and necessary distributing lines, will cost approximately $1,000,000.

In addition to this, foundations are ready at the Riverside station of the company in Minneapolis for installation of three new 1,360-hp. boilers which have been ordered and are expected to be in operation this year. The cost will be about $500,000. Work also is under way to increase the coal and ash handling capacity of the Riverside station.

A 4,000-hp. steam turbine has been ordered for the Fargo (N. D.) plant of the Union Light, Heat & Power Company division of the Northern States Power Company. This, with the necessary additional boiler capacity, will cost approximately $300,000. It is expected that the installation will be completed next fall.

Total construction now under way at the Northern States Power properties amounts to about $5,000,000.

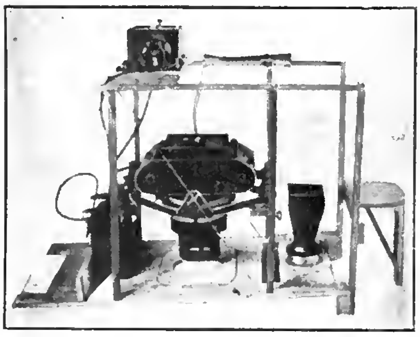
## Purchase of Utilities at Montgomery Approved

Formal approval of the purchase by the Alabama Power Company of the properties of the Montgomery Light & Traction Company, the Montgomery Light & Water Power Company, the Alabama Traction Company, the People's Ice & Electric Company and the Power Transmission Company, all of Montgomery, Ala., was contained in an order issued last week by the Alabama Public Service Commission. The purchase price is $6,200,000, but this price, the commission sets out, is not to affect any value which the commission may place on the properties for rate-making purposes. In addition to approving the purchase of the Montgomery utilities the commission also granted the power company's petition for authority to sell $4,000,000 worth of bonds,

the proceeds to be used in improvements and extensions by the power company and to meet outstanding obligations. Both the Montgomery Light & Water Power Company and the Montgomery Light & Traction Company are to be taken out of the hands of the receiver immediately.

## Hydro-Electric Survey by Airplane in South

The Alabama Power Company is preparing to survey the section of Alabama through which the Tallapoosa River flows by means of the airplane photographic method. The work of surveying will begin about the middle of March. The plane which will be used is a Breguet bombing type biplane, carrying five passengers, a pilot and 600 lb. of equipment. It is driven by a 300-hp., twelve-cylinder V-type Renault motor, which gives a maximum flying speed of 135 miles per hour, and is the same type of ship that is now used in the London-Paris passenger service.



CAMERA USED FOR TOPOGRAPHICAL SURVEY WITH VIEW TO POWER DEVELOPMENT

The company plans to use a camera of the Eastman K-1 type, with a single focal lens of 10 in., a 12-in. mapping cone, Venturi vacuum tube, power battery, speed-control unit and view finder. This camera will be mounted over an aperture in the cockpit of the plane on a special vibrationless support and contain a film 75 ft. long, sufficient for 100 exposures. In order to obtain photographs on the desired scale of 800 ft. to the inch, it will be necessary for the plane to fly at an altitude of approximately 9,600 ft. above the area to be photographed.

The result will be a map free from the blunders common to ordinary maps and showing a wealth of detail which it would not be possible to obtain by land surveying except at a prohibitive cost. Only sixty to seventy-five actual hours of flying are estimated to be necessary to complete the work, though two weeks to four months may be required, depending on weather conditions. The company estimates that it would take a land surveying company at least eighteen months to do the same work if that force were no larger than the one to be employed for the air survey, which will consist of about seventy office and field men. A saving of about 50 per cent is expected.

# Brief News Notes

**A Big Doherty Project.**—A permit granted by the Federal Power Commission to the Empire District Electric Company of Joplin, a Doherty property, foreshadows a 60,000-hp. hydro-electric project at Table Rock, near Branson, on the White River, where a great reservoir will be formed. The projected plant will be complementary to the one installed at Powersite, Taney County, ten years ago.

**Hagerstown May Sell Light, but Not Power.**—Thirteen taxpayers of Hagerstown, Md., who instituted injunction proceedings to restrain city officials from building a new municipal electric plant at a cost of $300,000 because the officials failed first to secure consent of the Maryland Public Service Commission, have obtained a court ruling that the city officials had no authority to erect a plant to generate electricity and sell it for power purposes, although they had the right to manufacture and sell electricity for lighting purposes. The city will carry its contention to the Maryland Court of Appeals.

**Bonds for Kahokia Plant Authorized.**—The Illinois Commerce Commission has granted the East St. Louis Light & Power Company authority to issue $11,000,000 5 per cent bonds to be used in the acquisition of the Kahokia Power Company plant, now under construction at East St. Louis. The project also embraces acquisition of the properties of the East St. Louis & Suburban Company and the East St. Louis Railway. The corporate name of the East St. Louis Light & Power Company is to be changed to the Union Electric Light & Power Company of Illinois.

**Power Merger of Arizona Plants.**—The Southern Arizona Power Company has been organized with a capital of $1,500,000 for the purpose of taking over the Nogales Electric Light & Power Company and the Arizona Gas & Electric Company, both of which operate plants at Nogales, Ariz. Prominent capitalists of Los Angeles and southern California are financing the new corporation. A large sum, it is reported, will be expended in extensions and betterments of the existing plants. Eventually power may be brought from northern Arizona to supply Nogales and the mining and other industries in its neighborhood.

**An Electrical Department in Builders and Architects' Journal.**—The Joint Committee for Business Development has made arrangements with the *American Builder Magazine*, Chicago, for a department in that publication, beginning with the March issue, devoted to electrification of all buildings. The *American Builder* is a handbook for those who plan and build and has a circulation of 55,000 copies a month, going to builders and architects in all parts of the United States and Canada. The new department in this newspaper will describe the complete electrification of twelve model homes with wiring layouts, lighting-fixture arrangements, use of appliances, etc. Decorative possibilities of lighting will be developed.

**Industrial Lighting Exhibit at Montreal.**—Under the auspices of the Electrical Co-operative Association of the Province of Quebec an industrial lighting exhibit has been held this week at Montreal, three demonstrations daily being given by S. G. Hibben of the Westinghouse Illumination Bureau, New York City.

**Milan Served by Interstate.**—The Interstate Public Service Company has signed a contract with the owners of the electric light company at Milan, Ind., to furnish energy from the company's plant at Aurora, Ind. Milan, with only 1,000 population, has recently built a new sanitarium which is completely electrified. A three-phase, 13,200-volt line to Aurora is being built.

**State Ownership Bill in Wisconsin.**—Legislation to bring about ultimate state ownership of privately owned and operated electric light and power companies in Wisconsin is sought by a bill which provides for the conservation and utilization of water sites by the state to develop electric power. This bill carries an appropriation for a survey of potential or undeveloped water-power sites in the state and prohibits the leasing or giving away of natural resources that may develop power.

**Northern Indiana Power Company Organization.**—The organization of the Northern Indiana Power Company, which has been noted in the news columns of the ELECTRICAL WORLD, is formally announced as follows: The consolidation takes in the Indiana Railways & Light Company, Wabash Water & Light Company, United Public Service Company, Noblesville Heat, Light & Power Company, Roann Light & Power Company and Sheridan Water, Light & Heat Company. Joseph H. Brewer, Grand Rapids, Mich., is the president of the new company. The other officers are: Vice-president and general counsel, L. J. Kirkpatrick; vice-president and treasurer, Harry R. Ellis; vice-president and general manager, Phil. H. Palmer. The Roann properties come under the management of the Wabash office and the Sheridan properties under the Noblesville management.

**Sleet Storm Puts Alabama Company on Its Mettle.**—Almost the whole construction department in the Birmingham district of the Alabama Power Company turned out to help the operating department clear up line and telephone breaks caused by a heavy sleet storm early in the month. The failure of a steel tower between Bessemer and Magella badly crippled the service in Birmingham. Temporary service was restored in record time by stringing the 110,000-volt "A" line to convenient trees until the steel tower could be replaced. The efficiency of the relay system was also demonstrated as every line that

sent in a trouble report was properly cleared and not a single faulty relay operation was recorded. The company's radio broadcasting station was used to advantage in reporting the load and voltage every half hour to the generating plants and primary substations.

**Buffalo Improves Street Lighting.**—A new circuit of 200 inverted magnetite-arc lights has been installed for a distance of several miles along Niagara Street, Buffalo, by the Buffalo General Electric Company. This company has contracts for placing 800 street lamps of the same type in the business district of Buffalo during 1923.

**Milwaukee Utility Buys New Property.**—The Milwaukee Electric Railway & Light Company announces that it has acquired the plant and other equipment of the Dousman Electric Light & Power Company, 33 miles west of Milwaukee, from L. J. Bischel. The consideration was not made known.

**Potsdam (N. Y.) Central-Station Company Extends Service.**—The St. Lawrence Transmission Company of Potsdam, N. Y., has completed a 24-mile, three-phase, 22,000-volt high-tension transmission line from Potsdam to Waddington for distribution and municipal lighting in Waddington, Madrid and Chipman and for distribution along the route.

**How to Pay Off the War Debts.**—A Pittsburgh engineer has submitted a plan to the Canadian government for utilizing the waste power of Niagara Falls to pay the war debts of the world. He asserts that with the co-operation of Canada, Great Britain, Belgium and the United States this can be done in twenty-five years. He would simply dig two tunnels 80 ft. in diameter and 25 miles long between Lake Erie and Lake Ontario. Utilizing the 250-ft. head thus gained, he would generate 5,000,000 hp. of electrical energy a day and sell it within a radius of one thousand miles for an average price of $82 per horsepower-year. The engineer-philanthropist is sure the thing could be done for two hundred million dollars.

**Storage Capacity in Utah.**—Flood control through regulation of the storage capacity in reservoirs on the Sevier River is proposed by R. E. Caldwell, Utah State Engineer, who has compiled tables showing that in the nine years ending with 1921 the annual flow of water into the Piute Reservoir was sufficient to fill that reservoir during the months of January, February, March and April in seven of the nine years. The stream measurement data on the stream show conclusively that the larger flood season comes in May and June. Thus it appears advisable to empty the reservoir completely in January of each year and gradually to build up the storage from the floodwaters, preventing the river from overflowing its banks. Mr. Caldwell's plan is that the reservoirs on the lower Sevier shall build up their storage during the first few months of the year and the upper reservoirs utilize the waters during the later season.

**Southern Indiana Security Issue.**—Issuance of $3,266,900 of securities and $400,000 in 7 per cent preferred stock by the Southern Indiana Gas & Electric Company, which has its main office in Evansville, has been authorized by the Indiana Public Service Commission. The amounts will be used to replenish the company's treasury, for repairs and extensions made and to be made and to retire outstanding stocks and bonds. The bond issue will bear 6 per cent and mature in twenty-five years. The company spent about $800,000 last year for machinery and extensions.

**Dissipating Clouds with "Electric Sand."**—Precipitation has been caused and clouds have been made to disappear in a series of experiments conducted at McCook Field, Dayton, Ohio, according to a widely recorded announcement made by the experimenters, Prof. Wilder D. Bancroft of Cornell University and L. Francis Warren. The experiments were made with the co-operation of the Army Air Service. The clouds were made to disappear and precipitate their moisture by the dropping of electrically charged grains of sand upon them from airplanes, according to the experimenters. Professor Bancroft and Mr. Warren assert that the process will be of great value in the commercial world, as fogs over cities, harbors and flying fields can be made to disappear, thereby insuring safety to travel and transportation. They do not contend that in every instance rain or precipitation can be produced, as all clouds do not contain sufficient moisture.

# Associations and Societies

**National Safety Congress to Be Held at Buffalo.**—The National Safety Council will hold its national safety congress for 1923 at Buffalo on Oct. 1 to 5, according to announcement by W. H. Cameron, managing director.

**Butte Electrical Men Organize.**—Members of the electrical industry in Butte, Mont., have recently formed the Electric Club of Butte, to promote the personal welfare of the members and to improve electric service for the public. M. E. Buck was elected president, H. M. Latham vice-president, K. M. McNeill secretary, and W. C. Medhurst treasurer. The club has rooms in the Montana Electric Building.

**March Section Meetings of the A. I. E. E.**—The following Institute section meetings have been scheduled for March, 1923: Boston, March 13, "Design of Transformers and Other Features of Queenston Plant," by M. E. Skinner, and "Trend of Power Transformer Development," by M. O. Troy; Detroit-Ann Arbor, March 16, associated technical societies' meeting; Philadelphia, March 12, "Recent Developments in Thermionic Tubes," Saul Dushman; Pittsfield, March 1, "Behind the Screen with the Movie Makers," Rowland Rogers; Worcester, March 15, "The Development of Illumination," W. D'A. Ryan.

**Pacific Coast A. S. M. E. to Discuss Water Power.**—The first Pacific Coast regional convention of the American Society of Mechanical Engineers will be held in Los Angeles on April 16 to 18. H. A. Barre, electrical engineer for the Southern California Edison Company, will present a paper on "Mechanical Features in Design of Long-Distance Transmission Lines on Hydro-Electric Systems," and Robert Sibley, Pacific Coast consultant for the McGraw-Hill Company, one on "Industrial and Electrical Development on the Coast."

**American Physical Society.**—For the meeting of this society at Columbia University, New York City, today (Feb. 24) papers of electrical interest are scheduled as follows: "Dispersion of Light by an Electron Gas," by Leigh Page, Yale University; "The Cause of Ionization in the Carbon Arc," by K. T. Compton, Princeton University; "The Contact Electricity of Solid Dielectrics," by Harold F. Richards, Princeton University; "Duration of Resonance Radiation in Mercury Vapor," by Harold W. Webb, Columbia University; "The Change in the Emf. Between a Metal Plate and a Solution After Being Suddenly Brought Into Contact," by R. D. Kleeman and R. H. Bennett, Union College.

## Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

Pennsylvania State Association of Electrical Contractors and Dealers—Lancaster, Feb. 28. M. G. Sellers, 1518 Sansom St., Philadelphia.

Oklahoma Utilities Association—Oklahoma City, March 12-14. O. D. Hall, 1106 First National Bank Bldg., Oklahoma City.

Southwestern Division, N. E. L. A.—Oklahoma City, March 14-16. S. J. Ballinger, San Antonio Public Service Co., San Antonio, Tex.

Illinois State Electric Association—Chicago, March 14-15. R. V. Prather, 305 Mine Workers' Bldg., Springfield, Ill.

Wisconsin Utilities Association—Milwaukee, March 22-23. John N. Cadby, 445 Washington Bldg., Madison.

Tri-State Water and Light Association—Birmingham, April 17-20. W. F. Steiglitz, Columbia, S. C.

American Physical Society—Washington, April 21. D. C. Miller, Case School of Applied Science, Cleveland.

American Institute of Electrical Engineers—Spring convention, Pittsburgh, April 24-26; annual convention, Swampscott, Mass., June 25-29; Pacific Coast convention, Del Monte, Cal., Sept. 25-28.

American Electrochemical Society—New York, May 3-5. Colin G. Fink, Columbia University, New York.

Southwestern Public Service Association—Fort Worth, Tex., May 15-17. E. N. Wills, 403 Slaughter Bldg., Dallas, Tex.

Electrical Supply Jobbers' Association—executive committee and general meeting, Hot Springs, Va., May 21-25. Franklin Overbagh, 411 S. Clinton St., Chicago.

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

Electric Power Club—Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

Pacific Coast Electrical Association—San Francisco, June 19-22. S. H. Taylor, 527 Rialto Bldg., San Francisco.

American Society for Testing Materials—Atlantic City, June 25-29.

## Commission Rulings

**Suspension of Operation Not Justified by Failure of Competing Company to Furnish Energy.**—The suspension of operation by a public service company having a permit to operate should not, the Wisconsin Railroad Commission held in barring out the Badger Public Service Company from Calumet (ELECTRICAL WORLD, Dec. 2, page 1237), be excused as a justifiable or involuntary suspension on the ground that the failure to serve is due to the failure of a competing company to supply energy. The Wisconsin law, the commission asserted, regards each utility as a separate and self-sufficient entity.

**Rates for Traffic Lights.**—A flat rate for traffic light service, used by municipalities in streets and highways for the guidance and regulation of vehicles, was approved by the Michigan Public Utilities Commission for the Detroit Edison Company. Usually, the company stated, only one lamp is required at each traffic location. This lamp burns all night and is commonly allowed to burn continuously to save the trouble and expense of turning it on and off. The company held that the cost of making such installations was prohibitive and that they did not fall under any commercial classification. Ordinarily these lamps are not connected with street-lighting circuits. In cases where they are so connected the commission took note of the fact that the company applies the street-lighting rates.

**Proper Charge for Rural Service.**—The Badger Utility Company recently filed an application with the Wisconsin Railroad Commission for permission to establish a rule providing for a connecting charge of $110 for farmers desiring service from its high-tension line who did not take a share of stock at the time the line was built. Granting this petition, the commission said: "We must bear in mind that rural electric service as we know it now is not, as a general thing, capable of supporting the full cost of the service including a return on the capital, and, consequently, unless the rural customer is to pay a part or all of the construction cost, the service either will not be furnished or customers residing in cities and villages must make up the loss, or the loss must be carried by the utility. It is not fair to assume that utilities will generally extend service into rural districts at a loss nor that local customers should be required to make up that loss. Consequently, if the rural districts are to have electric service, rules must be approved which will provide proper conditions under which lines shall be constructed so that the service can be self-supporting. A refusal to approve the rule in this case might or might not adversely affect customers who desire to receive service from the line in question, but it would almost certainly have the effect of putting the company in a position where it could not afford to furnish extensions for other rural customers and where it is quite likely that the commission could not order the furnishing of such extensions since the failure to have a proper connection charge would mean that the extensions could not produce enough revenue to meet the cost of service."

**Invasion of Territory.**—The Morris & Somerset Electric Company brought complaint against the Commonwealth Electric Company and sought to prevent the authorization by the New Jersey Board of Public Utility Commissioners of the issue of securities by the latter company, charging that the Commonwealth company was infringing on the territory of the complainant. It appeared that the Commonwealth company had contracted to supply electrical energy to the Millburn Electric Company for distribution and for that purpose had agreed to construct a 33,000-volt transmission line to bring energy from its Morristown plant to the Millburn company's wires and also to supply twenty-nine customers along the route. The Morris & Somerset company claimed that this business belonged by right to it, but the board confirmed the Commonwealth company's contract and authorized the securities, holding that an electric utility which has extended into territory nearer to another utility's system than to its own should not be ousted when the other utility has made no effort to develop the territory and when there is not sufficient disparity in the cost of service to justify such action.

**Municipality Ordered to Lower Rates.**—Ordering a reduction of 25 per cent in the power rates made by the Borough of Vineland for customers outside the borough limits, the New Jersey Board of Public Utility Commissioners said: "As a part of the borough's electric operating revenue deductions no taxes are included, and in comparing its cost of operation with a private corporation an allowance for taxes should be made. In the case of privately operated electric utilities these amounted in 1921 to approximately 9 per cent of the gross revenues. An allowance should also be made for a higher cost of administration or management, inasmuch as almost invariably in the case of a municipal plant not all of the time of every municipal officer properly assignable to the operation thereof is charged as a part of the operating expenses. If no consideration were given to these two items in fixing rates to be charged the consumers of electrical energy would be getting all of the benefits accruing to the borough from the operation of the electric plant as a municipal undertaking. These benefits belong to the taxpayers as such and not to the consumers of electrical energy as such. In order to be fair to the former, the net return should be sufficient to include the amount which in the case of a private undertaking would be paid out for taxes and higher administration expenses."

## Recent Court Decisions

**Assumption of Risk by Lineman Using Hook Without Safety Catches a Question for Jury.**—In French vs. Southwestern Telegraph & Telephone Company, an action to recover damages for the death of a telephone company employee who fell while descending from a platform built on a high pole to ground by means of a hand line, because a hook by which the hand line was suspended from a wire slipped off the wire, the question of whether he assumed the risk of using this hand line, though the hooks were open and had no safety catches to prevent them from slipping from the wire, was held by the Court of Civil Appeals of Texas to have been rightly left for the decision of the jury, and a verdict for the plaintiff was therefore upheld. (245 S. W. 997.)*

**Ordinance Granting Franchise Fixing Maximum Charge a Contract.**—The Supreme Court of Nebraska has declared, in City of University Place vs. Lincoln Gas & Electric Light Company, that an ordinance reciting "that, in consideration of the rights and privileges granted herein, the grantees shall have a right to charge not in excess of $1.50 per 1,000 cu.ft. of gas," etc., which was accepted by the company, constituted a contract the obligation of which may not be impaired by either party. Whether or not the state, by the exercise of its paramount authority to regulate rates which may be charged by public utility corporations, could intervene upon a showing that the rate fixed by the contract was unreasonable or confiscatory was not decided. (191 N. W. 432.)

**Powers of Oklahoma Commission.**—From an order of the Oklahoma Corporation Commission directing the Oklahoma Natural Gas Company to furnish natural gas to the Chickasha Gas & Electric Company for distribution the first-named company appealed to the Oklahoma Supreme Court. Reversing the commission's decision, that court holds that where a public utility has undertaken and professes to serve the inhabitants of certain cities and towns within the state the commission has power, within constitutional and reasonable limitations, to compel such utility to serve all inhabitants thereof who may apply for such service, but that the commission is without power to compel a public utility to furnish its product to a community which it has not undertaken or professed to serve and which it is under no obligation to serve, since to require the utility to serve such community would be tantamount to the taking of private property for public use without just compensation. (211 Pac. 401.)

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

# Men of the Industry

Changes in Personnel
Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry

## Learned and Hecht Vice-Presidents Northern Illinois

John G. Learned and Julius L. Hecht, who have been elected vice-presidents of the Public Service Company of Northern Illinois, as was an-anounced in the Feb. 10 issue of the ELECTRICAL WORLD, have been identified with the electrical industry for a number of years. In 1898 Mr. Learned became associated with the Chicago Telephone Company, now the Illinois Bell Telephone Company, and on leaving that company two years later he became a salesman for the Commonwealth Edison Company. In 1905 he resigned from that organization to become general contract agent for the North Shore Electric Company, where he remained until 1911, when the company became part of the Public Service Company of Northern Illinois. At that time he was made general contract agent for the northern and western divisions, and in August of the following year he was made assistant to the vice-president of the company in charge of the commercial, advertising and right-of-way departments. Later he was made commercial and new-business manager, which position he held at the time of his recent promotion. Mr. Learned will continue in charge of the same division.

Julius L. Hecht has been general superintendent since 1921. He was graduated from the Massachusetts Institute of Technology in 1904, and the following year he became construction engineer for the North Shore Electric Company. In 1907 he was made mechanical engineer in charge of stations. In 1915 he was appointed superintendent of electrical production for the Public Service Company and in 1921 assistant to the vice-president in charge of operation with the duties of general superintendent, the position he held at the time of his promotion to the vice-presidency. Mr. Hecht will have charge of the engineering and operation departments.

**John O. Montignani**, formerly engineer of electric distribution and division superintendent with the Rochester Gas & Electric Corporation, is now associated with the Westchester Lighting Company, Mount Vernon, N. Y., as assistant electrical engineer.

**Harold P. Dayton**, who for three years has been the assistant treasurer of the Haverhill Gaslight Company, has been transferred to a similar position with the Truckee River Power Company at Reno, Nev. The Reno company is under the management of Stone & Webster, Inc., and serves an extensive territory in the western part of the state. Mr. Dayton has been associated with the Stone & Webster organization since 1914 and was a traveling auditor for several years before going to Haverhill.

## Director of Washington Committee on Utility Information

E. H. Thomas, who has been placed in charge of the newly organized Washington Committee on Public Utility Information as director, with offices in the Henry Building, Seattle, is a newspaper man of broad experience, covering a period of twenty-seven years. He was formerly managing editor of the Seattle *Post-Intelligencer*.

E. H. THOMAS

In addition he has had eight years' experience in public utility publicity work, having been publicity director for the Puget Sound Power & Light Company.

As Mr. Thomas sees it, the committee of which he is the director exists to furnish accurate information and facts about the public utility business to any citizen or group of citizens. The long experience which he has had as an active newspaper man has taught him the things in which the public are interested, and his previous association with public utility work has furnished him with a fund of information as to the sources contained within the utilities themselves for obtaining material that has a popular appeal and at the same time is grounded on facts.

**Ralph E. Thurston**, manager of the Putnam (Conn.) Light & Power Company, became manager of the Danielson & Plainfield Gas & Electric Company on Feb. 1. Mr. Thurston retains the managership of the Putnam utility.

## B. C. Edgar Merger Company's General Manager

B. C. Edgar, who was vice-president and general manager of the Chattanooga Railway & Light Company and the Tennessee Power Company before they were merged with the Chattanooga & Tennessee River Power Company into the Tennessee Electric Power Company, retains his former title in the merger company. Mr. Edgar is also associated with the Nashville Railway & Light Company and at one time was assistant general superintendent of the Columbus (Ohio) Railway, Power & Light Company. W. C. Campbell remains with the new company in the capacity of assistant to the vice-president and general manager. The engineering and operating department of the new company retains most of the engineers who were with the component companies, but in slightly different capacities. J. A. Longley is general superintendent in charge of all engineering and operation of the power and transmission department, H. Crumbliss, Jr., chief civil engineer, J. R. Anderson, chief hydraulic engineer, George W. Christians and O. J. Miller electrical and mechanical engineers on new development work, E. C. Williamson electrical engineer on all other work than that of new development, M. M. Roddey superintendent of operation, and F. R. Atkins superintendent of power and substations. E. D. Reed remains as general superintendent of the Chattanooga district, which is the largest single center of energy utilization. H. B. Whitman is assistant general superintendent of both departments.

E. H. Lewis, who has recently been appointed general superintendent of the St. Louis County division of the Union Electric Light & Power Company and general manager of the St. Louis County Gas Company, became associated with these organizations in 1915, when he joined the engineering and sales departments. In 1920 Mr. Lewis became assistant treasurer of both companies, and one year later he was appointed treasurer of the St. Louis County Gas Company. He filled this office and that of assistant treasurer of the Union Electric Light & Power Company until his recent promotion.

L. F. Leurey, consulting electrical engineer of San Francisco, was elected to the office of president of the San Francisco Electrical Development League at the election held at the annual meeting on Feb. 12. The present secretary-treasurer, J. W. Mahoney, of the General Electric Company in the city, was re-elected by the members of the league. A. U. Brandt, electrical engineer, San Francisco division of the Pacific Gas & Electric Company; D. I. Cone, protection engineer of the Pacific Telephone & Telegraph Company, San Francisco, and C. Todt, Pacific States Electric Company, were named as the new members of the executive committee of the electrical association.

## P. B. Postlethwaite Vice-President of Wagner Electric Corporation

Preston Barr Postlethwaite, one of the newly elected vice-presidents of the Wagner Electric Corporation, has been associated with that organization since 1909, when he took its apprentice course. In February, 1910, he went to the Cincinnati office as a salesman, where he became branch manager in 1913 and district manager in 1915. Mr. Postlethwaite was called to the Wagner Electric factory at St. Louis in November, 1916, to organize and take charge of the service department, and three years later he also took over the automotive department. His experience as vice-president of several subsidiary companies of the Wagner Electric Corporation made him the natural choice for the vice-presidency of the newly formed Wagner Electric Corporation. Mr. Postlethwaite was born in Huntington, Pa., and is a graduate of Pennsylvania State College.

**J. L. Stannard** of San Francisco was named chief engineer for the construction of the first unit of Tacoma's new five-million-dollar Lake Cushman power project.

**William Seiple**, until recently an official of the Indiana Street Railway Company, is now associated with the Pennsylvania Power & Light Company in the Wilkes-Barre district.

**L. H. Ames** is the new superintendent at the Muscle Shoals plant of the Alabama Power Company, succeeding C. B. McManus, who was recently promoted to the position of manager of the western division.

**Norris C. Husted**, who has been a sales engineer for Hubbard & Company for the past five years, has been made manager of the Hubbard Pressed Steel Company, Niles, Ohio, a subsidiary of Hubbard & Company.

**Homer G. Hall**, who has been covering the territory in the Madison (Wis.) section for the General Electric Company for many years, has severed his connections with that company to become associated with the Julius Andrae & Sons Company of Milwaukee.

**F. O. Evertz**, superintendent of the electrical department of the Ohio Inspection Bureau, was recently elected president of the Western Association of Electrical Inspectors. Mr. Evertz has been an active member of this body and has served as vice-president and a member of the board of directors

**T. T. McLemore** has replaced E. R. Wall as division superintendent of the western division of the Alabama Power Company. Mr. Wall resigned to accept a position with the power department of the Birmingham Railway, Light & Power Company. W. M. Craven will act as assistant division superintendent.

**Chief Justice E. E. Corfman** of Salt Lake City, for six years head of the Utah Supreme Court, has been appointed by Governor Mabey as a member of the Public Utilities Commission of that state to fill the vacancy caused by the recent death of Judge A. R. Heywood. Judge Corfman has been a prominent member of the legal profession in Utah for many years.

**Clifford G. Hillier** has been appointed manager of the merchandising department of the Westinghouse Electric & Manufacturing Company, New England office, with headquarters in Boston. He succeeds F. L. Nason, who has been appointed assistant manager of the central station department of the Boston office.

## C. J. Stoll Works Manager Hawthorne Plant of Western Electric

C. J. Stoll has been appointed works manager, to remain in Chicago, upon the transfer to New York of the executive headquarters for the Western Electric Hawthorne plant. After obtaining his degree of electrical engineer from

C. J. Stoll

Penn State College, Mr. Stoll joined the Western Electric Company in 1903. He received charge of its new-apparatus design department in 1905 and six years later became head of the manufacturing branch of the Western Electric shop in New York. In 1912 he went to Belgium as shop superintendent of the Antwerp branch, returning to America a year after the war had started. Since that time he has been operating superintendent, technical superintendent and assistant general superintendent of the Hawthorne works.

**John P. Crowley** of St. Paul was recently elected vice-president and general manager of the St. Croix Power Company, Somerset, Wis.

**Kempster B. Miller** has resigned as general manager of the North Electric Manufacturing Company, Gallion, Ohio, to enter the consulting engineering field in Pasadena, Cal.

**W. M. Casey**, who has been superintendent of transportation for the International Railway Company of Buffalo, has gone to Atlanta to become superintendent of the Georgia Railway & Power Company.

**O. D. Allen** has been appointed manager of the Coghlin Electric Company, Worcester, Mass., electrical supply jobbers and contractor-dealers.

**Augustus C. Smith**, sales manager of the Buffalo General Electric Company, was elected chairman of the electrical group of the Chamber of Commerce of Buffalo.

**William T. Walker** has recently become sales manager and vice-president of the Jeannin Electric Company, Toledo, manufacturers of single-phase motors. Mr. Walker was formerly connected with the autombile industry.

**Renshaw Borie** is now associated with McClellan & Junkersfeld, Inc., in their work of engineering, construction and management and is in charge of their Philadelphia office.

**W. J. Jockers**, sales manager of the St. Paul Electric Company, was made vice-president and a member of the board of directors at a recent meeting of that body. Mr. Jockers will continue in his capacity as sales manager in addition to his new duties.

**Cloyd M. Chapman**, who has been active in the work of the American Society of Testing Materials and the American Concrete Institute, has become affiliated with Dwight P. Robinson & Company, Inc., as consulting materials engineer.

**C. F. MacMurray** has replaced J. S. Dales as president and general manager of the Colon Electric & Ice Supply Company, vice-president and general manager of the Ciá Panamena de Fuerza y Luz and of the Ciá Panamena de Telefonos and general manager of the Panama Electric Company. Mr. MacMurray was graduated from Syracuse (N. Y.) University in 1906, and previous to occupying his present position he was manager of the Colon Electric & Ice Supply Company.

**James L. Mahon**, who for seven years has held the position of advertising manager of the P. A. Geier Company of Cleveland, was appointed merchandising manager of that company on Jan. 1. With Carl M. Randel, director of sales, he will be in charge of the merchandising policies of the company's entire electrical output. Prior to his connection with the Geier company, Mr. Mahon was with the Buckeye Lamp Division, a branch of the National Lamp Works of General Electric Company, and he was also for some months an officer of the Carpenter-Kingston Advertising Company of Cleveland. For the time being Mr. Mahon will continue to supervise the company's advertising in addition to his new duties.

# Obituary

**Patrick C. Fitzpatrick** of Springfield, Mass., an electrical contractor since 1891 and one of the longest established in that section of Massachusetts, died Feb. 3 in St. Petersburg, Fla., at the age of sixty-three.

# Manufacturing and Markets

Devoted to the Discussion of Business and Economic Problems of the Producer and Distributor, with Market Reports, Trade Activities, Foreign and Construction News

## Used Machinery—A New Industry Asset

**How It Has Shaken Off the Blight of the Second-Hand Idea and Come to Be an Economic Service to the Central Station**

By Frank MacGovern
MacGovern & Company, New York

MEN of industry are rapidly developing a new mental attitude toward power equipment and other machinery that has been used and has come again into the market. The blighting influence of the term "second-hand" is being shaken off, and as "used machinery" it is taking its place in the market with all the respect due to legitimate goods when openly sold to people of standing in the community by concerns of unquestioned responsibility.

The stigma of the "second-hand" idea is not hard to trace back to the early days when trade was principally confined to crops and domestic animals, jewels and works of art, clothing and implements for personal use. Crops and animals, jewels and art objects were freely bartered and lost no value in changing hands. But personal effects naturally were depreciated with personal use and contact and were sold at a sacrifice more because their "social standing" was impaired than because of actual decreased value. They were called "second-hand" and the term has carried a taint. Buy a horse or a cow from any one and you pay its worth, but a thing called "second-hand" is expected to be priced down because of the bad name.

### Influence of the Used Car

The automobile brought new thinking on the subject, because people were continually buying new and better cars and here were their old cars still good for service. So other people have bought them until there is no social stigma today in buying a "used" car—which may, in fact, be a rebuilt car—and we do not even call it "second-hand." True, used cars have been greatly depreciated in price, but the improvement of automobiles has been very rapid and the element of style influences the demand in a degree out of all comparison with more standard types of machinery. As a matter of fact, there has been very little change in the design of electrical machinery during the last eight years or more. There have been very few exceptions, the conspicuous case being the large sizes of turbine, in which there has been improvement in efficiency.

Frank MacGovern

Therefore the fact that the equipment may be a few years old has no effect upon it. Its efficiency and its worth depend not upon its age but its condition.

The stresses of the war have brought this same kind of a change in the attitude of industry toward used machinery. During the great need any piece of available "used" machinery was eagerly grabbed up for the value that was in it. And with the end of the war and the arresting of plant expansion a large quantity of machinery was thrown on the market, by the government and by manufacturers, some unused, some used but little, and its intrinsic value was so palpable that it has all been accepted as "used" and not "second-hand" equipment and has been bought according to its worth at what price negotiation could develop but without direct depreciation for any loss of "social" standing.

The great war plants at Hopewell, Nitro, Nashville and other points were dispensed in this way. Moreover, a great deal of absolutely new machinery has been brought onto the market, through a variety of causes, which must be sold by owners other than the original manufacturers, and this equipment too is sold by the used-machinery dealer. A recent spectacular example was the 20,000-kva. power plant which the government erected at Edgewood Arsenal. This plant has within the month been acquired by my company. There were two turbines with condensers and auxiliaries aggregating 17,500 kw., a complete switchboard with bench control of remote-operated oil breakers, 8,230 hp. in boilers with stokers, superheaters and soot blowers, and all the other equipment going to make up a complete power plant.

The electrical and power machinery has already been resold to the Denver Tramways Company, thus bringing to the Denver company the opportunity to purchase an extensive new equipment at a price which would have been far greater but for the services of the used-machinery dealer.

This extensive equipment had never been installed, but twelve years ago there would have been some hesitation on the part of the purchaser to buy equipment of this importance without a manufacturer's guarantee. The reputation of this used-machinery dealer has become so stabilized, however, because of the large amount of used equipment that is being sold, that the fact that this machinery is not absolutely new is no longer any serious obstacle to its resale and utilization.

### How Used Machinery Market Helps

But the vicissitudes of peace and progress are greater than the urgencies of war when it comes to electrical machinery. The growth of the industry is constantly forcing the abandonment of used machinery. Light and power companies are constantly buying new and larger machines and releasing smaller units,

which are bought by industrial plants or other utilities. Private plants are abandoned by companies that decide to take on central-station service. This equipment thereby becomes available to industry and can be acquired at considerably less than the first cost. In small stations this often makes possible the taking on of additional load in waiting business that could not be immediately financed if new apparatus at the full price had to be purchased.

The maintenance of an established market for used machinery, therefore, renders an economic service of great value to the industry. It establishes a place to sell used machinery and a place to buy it, and the dealer contributes also a further service of adaptation, for he rebuilds machinery, changing the voltage or some other desired detail or combining two machines into a motor-generator set as the customers' needs require. Another important service comes in the matter of deliveries, for in these days when manufacturers are sold far ahead of their capacity to produce, used machinery can be secured to meet emergencies.

This often makes possible the taking over of a private plant, for the ability of the central station to secure the load often hinges on the satisfactory sale of the installed machinery. Often it assists the enlargement of an industrial plant in the same way.

### Responsibility Makes Safety

One of the old obstacles to the sale of used equipment was the feeling that it was buying a "pig in a poke," but those days have passed. The business has been lifted to a dignified position by the development of used-machinery firms whose standards are of the highest and whose responsibility is ample.

The value of a boiler is established by the insurance certificate that covers it. The value of a turbine, an engine or other equipment can be established by experts. The responsibility of the firm that sells the used machinery is a matter of record and reputation.

Buying from a dealer whose good name and ample resources stand behind his guarantee is no less safe and profitable than buying from the maker of the apparatus. Therefore the resale of used machinery has grown into an established business of great volume in recent years and is resulting in a service to the central stations and industrial plants of this country of inestimable value.

There is hardly a prominent central station or important manufacturing concern in this country or in Canada that has not purchased used power equipment within the last dozen years, and the sales to smaller companies are large. The used-machinery business, in short, has won social standing and shaken off the damning influence of the old second-hand idea. In so doing it has become a distinct asset to the electrical industry.

# Export Business for the Electrical Jobber

**Some Definite Advice as to Existing Opportunities and the Methods by Which Foreign Trade May Be Developed by the Wholesaler**

By R. A. Lundquist
Chief Electrical Equipment Division, United States Bureau of Foreign and Domestic Commerce

Many instances exist where buyers in the less developed markets of the world cannot place large orders and where their requirements cover only a few each of numerous items. There are generally no regular import merchants with stocks of electrical goods in such places, and American electrical jobbers in strategic locations can well afford to cater to that class of trade, which is now often handled through indirect channels that do not tend to develop the possibilities that exist.

Again, it often happens that a foreign electrical dealer who normally does business in considerable volume through a general export house or other channels may urgently need a particular class of material or may want a modest mixed order of rather technical items shipped promptly. Such cases occur regularly in the electrical trade where a consumer calls for something out of the ordinary, and they present real opportunities for jobbers who can fill such orders without delay. It is a question of service largely—service rendered with promptness, efficiency and a full understanding of what is wanted—and the purchaser is willing to pay a margin to the jobber for that service. The smallness of the order and the limited quantity of individual items involved do not make such business attractive to manufacturers, but it should be profitable to jobbers, since it will invariably exceed in amount the average domestic order.

The business done by general export houses has been confined mainly to rather staple lines purchased in fair quantities from manufacturers, with the export houses acting as buying agents and shippers for the foreign customers. Much of such existing business will remain in the hands of general export firms in view of the fact that such items are frequently a part of a considerable order for mixed lines of merchandise, and that the business connections are of long standing. However, while general export houses do handle small miscellaneous orders of purely electrical goods, they are seldom prepared to fill promptly orders involving more or less technical items, nor are they in a position usually to seek such business aggressively from the foreign buyers. Their field lies largely in dealing with manufacturers on behalf of foreign clients who anticipate their requirements well in advance and who therefore buy in reasonably large quantities.

### The Promising Field

Canada is so closely bound up with our domestic merchandising that others of our neighbors present more promising fields. Mexico, the Central American republics, the West Indies, and to some extent a few of the northern countries of South America, offer the best prospects for the class of trade first discussed. There are no electrical importers who cover these countries throughout, and the electrical dealers and electric lighting companies in outlying places often do their buying of American supplies through indirect non-technical channels, though it must be said that more efficient means are usually provided for European goods.

Where prompt service is the controlling factor, or where special items are needed in small quantities, jobbers are able to sell goods to larger markets still—to Australia, New Zealand, China, India and to most of South America. This latter class of business is, of course, not steady, but it is worth while catering to.

Jobbers cannot afford to spend a great deal of money to open up ac-

counts in markets that promise only a limited volume of business. Catalogs sent to a hand-picked list are probably the most efficient means of approach, but the way for sending such catalogs should be paved by well-prepared letters describing the activities of the company and courteously requesting permission to do so. Unsolicited catalogs mailed to foreign firms, upon which they may be required to pay duty—and not infrequently short postage—are a source of irritation. Duties on catalogs should be arranged for by the sender, if possible, but at any rate the foreign firms should be informed as to what is to be sent them and under what conditions. One point that the jobber should emphasize is that he is purely a wholesaler and that he is seeking business on the basis of service—shipment from stock, assortment of items in quantities that will meet the needs of the buyer, and technical understanding of his requirements.

Business connections in outlying countries should be put on a more personal basis than is common in this country. Circular letters should be avoided so far as possible. Announcements of new lines or of special opportunities should be made in a more quiet manner than usual for the American trade. The foreign buyer wants to be kept advised of all new developments in the electrical field, but he appreciates them most fully when they are outlined to him in concise and courteous terms and with complete information.

Jobbers catering to foreign trade should make specific and uniform arrangements with their overseas customers regarding cable messages and their charges. A foreign firm which cables for quotations is not satisfied with a price list by mail. Cable messages, even when well coded, are expensive, and the charges may be all out of proportion to the volume of the particular transaction to which they pertain, but a policy can be determined upon that will be just to both buyer and seller. In the long run they are part of the margin the foreign buyer pays for prompt service, and he will hardly cable unless his needs are urgent and will bear the expense.

### SELLING TERMS

Foreign electrical dealers and central-station companies with which jobbers can establish connections will not as a rule ask for better terms than do American buyers of the same class. Upon beginning relations most foreign buyers are willing to establish credits with bankers in the port of shipment so that the goods will be paid for when the draft, with the documents attached, is presented at a bank. Where other terms are suggested for initial orders or where business relations have been in effect for a reasonable period, and sixty or ninety days' time is desired by the customer, it is always possible to obtain credit ratings from the usual commercial sources or to get insurance against the credit risk if advisable. Where goods are sold to established customers on such terms, the jobber will usually be able to discount the drafts through his usual banking connections.

There are certain specified routine details to be attended to in shipping goods abroad, there are various difficulties in language to be met, but on the whole the so-called intricacies of foreign trade disappear before common sense. The foreign buyers of electrical goods are reasonable business men with a good knowledge of what they want and with a willingness to play fair. Much of their business will continue to go direct to manufacturers and some to general export houses, but there is a certain portion of it that should and can fall to the electrical jobber.

# Business Conditions

A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand

## Atlanta Collections Better

Jobbers in Atlanta report January collections as unusually good, even above optimistic estimates, with one jobber stating that his February collections are on a par with those of January. Another jobber, however, states that there seems to be a tendency on the part of his customers to pay more slowly than in the prior month. As a whole, collections in north and middle Georgia are in better shape than in the southern portion of the state.

An encouraging sign is that an increasing number of purchasers are taking cash discounts, a year ago these purchasers being unable to pay on even a sixty or ninety-day basis. Credits are still extended with care, but on the whole it can be said that credit is being extended on a less stringent basis than has been the case for some time. The experience of 1920, however, will serve to make credit men quite conservative in opening up new credit lines.

## New England Storage-Battery Trade Good

Sales of storage batteries are being maintained in New England on a scale promising better business this year, and while delivery conditions cause some anxiety, recent factory enlargements are helping to meet the current requirements of this and other sections of the country. Replacement orders are coming in well, and of late increased interest has been shown in road trucks and in industrial electrics. A prominent distributing house looks for an excellent year in lighter delivery-wagon battery sales, especially in the laundry and bakery fields.

Fair business is reported in radio batteries, notwithstanding the extending use of dry cells in some receiving sets. The season has not yet opened in starting and lighting batteries. Increasing applications of batteries are apparent in railroad car-lighting service. Stocks are none too large, and some shipments are being made on a four weeks' basis for varied battery service. Prices have shown a tendency to increase slightly in a few lines lately.

## Fixture Sales Are Improving

Observation of the demand for fixtures so far this year gives ground for optimism, and if prices continue fairly stable, jobbers and dealers handling this business intelligently should secure an excellent turnover. For months the demand for portable lamps has been active and growing, and the general improvement of business conditions throughout the country has been accompanied by decisions to build new homes and to refurnish old residences and install better lighting in industrial and mercantile establishments. The work of such an organization as the Bureau for Better Illumination at Boston and the increased emphasis being placed upon illumination engineering in central-station circles are bearing fruit.

The desire to move accumulated stocks has resulted in some quarters in price cutting, but it is believed this is affecting only a small proportion of the total volume of business. The popularity of styles is a potent factor in this branch of the trade, and nothing like saturation in design development is in sight. Unquestionably the recent discoveries in Egyptian archeology will be reflected in the design of high-grade illumination equipment, and the use of electric lighting in the actual investigations in the Valley of the Kings represents only the initial contact of the electrical material market with this epoch-making research.

## Comparative Prices of Station Supplies

| | Current Price | Four Weeks Ago | One Year Ago |
|---|---|---|---|
| Soft steel bars, per lb. | \$0.0303 | \$0.0296 | \$0.0247 |
| Cold finished shafting, per lb. | 0.0397 | 0.0378 | 0.0336 |
| Brass rods, per lb. | 0.1804 | 0.1742 | 0.155 |
| Solder (half and half), per lb. | 0.2617 | 0.2425 | 0.2075 |
| Cotton waste, per lb. | 0.1181 | 0.1175 | 0.106 |
| Washers, cast iron (½-in.), per 100 lb. | 4.33 | 4.33 | 3.83 |
| Emery, disks, cloth, No. 1, 6-in. diameter, per 100 | 2.96 | 2.96 | 3.11 |
| Machine oil, per gal. | 0.349 | 0.36 | 0.40 |
| Belting, leather, medium, off list | 49% | 49% | 46% |
| Machine bolts, up to 1-in. x 30-in., off list | 51⅓% | 51⅓% | 64⅔% |

## Important Data on Electrical Industry for 1921

The Department of Commerce has just announced that, according to reports made to the Bureau of the Census, the value of products of establishments primarily engaged in the manufacture of electrical machinery, apparatus and supplies amounted to \$833,986,000 in 1921, as compared with \$997,968,000 in 1919 and \$335,170,000 in 1914, a decrease of 16.4 per cent from 1919 to 1921, but an increase of 148.8 per cent for the seven-year period from 1914 to 1921.

In addition, electrical products to the value of \$49,003,000 in 1921, \$65,558,000 in 1919 and \$24,262,000 in 1914 were reported by establishments classified in other industries. Electric washing machines, glass and porcelain electrical supplies, electric signs and electric lighting fixtures have been classified under other industry captions, and statistics of their production will be included with those for "washing machines," "glass," "pottery," "signs and advertising novelties" and "gas and electric fixtures."

Of the 1,333 establishments reporting products valued at \$5,000 and over in 1921, 220 were located in New York, 166 in Illinois, 161 in Ohio, 116 in Pennsylvania, 113 in New Jersey, 105 in Massachusetts, 73 in California, 60 in Connecticut, 54 in Wisconsin, 49 in Indiana, 47 in Missouri, 40 in Michigan, 16 in Minnesota, 13 in Washington, 12 each in Kentucky and Rhode Island, 11 in Maryland, 8 in New Hampshire, 7 each in Colorado, Iowa, and West Virginia, 6 in Oregon, 5 in Nebraska, 4 in Texas, 3 each in Louisiana, North Carolina and Virginia, 2 each in Alabama, District of Columbia and Oklahoma, and 1 each in Forida, Georgia, Kansas, North Dakota, Utah and Vermont.

Four states reported products valued at more than \$100,000,000 each. Illinois, the leading state in 1921, produced 20.2 per cent of the total value of products in that year, New York 17.9 per cent, Pennsylvania 13.9 per cent, and Ohio 12.3 per cent.

In January, the month of maximum employment, 187,075 wage earners were reported, and in July, the month of minimum employment, 149,697, the minimum representing 80 per cent of the maximum. The average number employed during 1921 was 161,204 as compared with 212,374 in 1919 and 118,078 in 1914.

The general statistics for 1921, 1919, and 1914 are summarized in the table. The figures for 1921 are preliminary and subject to such change and correction as may be found necessary from a further examination of the original reports.

ELECTRICAL MANUFACTURING DATA—1914-1921

| | 1921 | 1919 | 1914* |
|---|---|---|---|
| Number of establishments | 1,333 | 1,315 | 874 |
| Persons engaged | 201,952 | 271,912 | 144,712 |
| Proprietors and firm members | 580 | 473 | 368 |
| Salaried employees | 40,168 | 59,065 | 26,266 |
| Wage earners (average number) | 161,204 | 212,374 | 118,078 |
| Salaries and wages | \$309,936,000 | \$336,369,000 | \$109,098,000 |
| Salaries | 115,996,000 | 98,180,000 | 35,291,000 |
| Wages | 193,940,000 | 238,189,000 | 73,807,000 |
| Paid for contract work | 925,000 | 1,218,000 | 291,000 |
| Cost of materials | 344,070,000 | 425,098,000 | 154,728,000 |
| Value of products | 833,986,000 | 997,968,000 | 335,170,000 |
| Value added by manufacture† | 489,916,000 | 572,870,000 | 180,442,000 |

*Statistics for establishments with products valued at less than \$5,000 are not included in the figures for 1921; 126 establishments of this class reported 117 wage earners and products aggregating \$351,000 in value. For 1919, however, data for 89 establishments of this class, reporting 80 wage earners and products valued at \$253,000, and for 1914, data for 156 such establishments, with 204 wage earners and products valued at \$440,000, are included in all items with the exception of "number of establishments."

† Value of products less cost of materials.

## U. S. Business Men to Meet British

One thousand business men from this country will join one thousand business men in Great Britain next spring in London, at a conference to promote the development of trade between the two countries, and to try to solve economic problems in which both countries are interested. This was announced recently by F. A. Wilson-Lawrenson, president of the Civitan Club, at a luncheon meeting at the Hotel Astor.

## Credit Situation in Portland and Seattle Reported Easier

Collections in the Portland-Seattle territory when compared with those of one month ago are easier with the exception of contractor-dealer accounts. One failure is reported in the retail trade this week and many dealers are having trouble to meet their obligations. However, jobbers and contractors are prospering, while the dealers are experiencing competition from the department stores and other small general stores in outlying districts. Outstanding accounts throughout the Northwest average forty-five days.

## The Metal Market

### Consumers Continue Extremely Active—Every Week Sees Further Expansions Indicated

Metal consumers continue extremely active, and all metal sellers are highly optimistic for the future. Every week sees further expansions indicated, and it is hard to see why the current year will not be a banner one for practically all non-ferrous metals. Most of the activity is confined to domestic business, but it is felt that a corresponding foreign demand for metals, although likely to be delayed longer than was expected, is nevertheless sure to develop. This foreign demand may finally arrive just in time to take up any slack in domestic business. The copper market at last seems to be permanently on the upgrade; lead is as strong as ever; tin is advancing again, and zinc has again taken a turn for the better.

NEW YORK METAL MARKET PRICES

| | Feb. 13, 1923 Cents per Pound | Feb. 20, 1923 Cents per Pound |
|---|---|---|
| Copper | | |
| Electrolytic | 15.12½ | 15.12½ |
| Lead, Am. S. & R. price | 8.00 | 8.00 |
| Antimony | 7.50 | 7.50 |
| Nickel, ingot | 30.00 | 30.00 |
| Zinc, spot | 7.00 | 7.05 |
| Tin Straits | 39.00 | 40.00 |
| Aluminum, 98 to 99 per cent | 22.00–23.00 | 23.00 |

Copper has shown surprisingly little tendency to linger at the 15-cent delivered level, which was supposed to be rather a stumbling block. Since Friday no copper has been obtainable at that price unless the consumer was extremely favorably situated. Sellers are not anxious to sell further ahead than April without getting a premium, as they feel that the price tendency will continue upward. At the same time, many producers are well sold ahead for the next three months, so the situation is fundamentally sound. Refinery deliveries in January were well over 200,000,000 lb. and are said to have been, with one exception, larger than those of any other month since the war.

The telephone and telegraph and electrical industries generally continue extremely active and are taking extraordinarily large tonnages of copper.

### Copper and Brass Products

Copper, brass and bronze mills quote the following prices on brass and copper products:

Copper wire, 17.25 cents net, mill; brass wire, 19.5 to 21.5 cents; copper sheets, 22.50 cents; copper rods, 21 cents; brass rods, 17.50 to 21.62½ cents; sheet brass, 19.25 to 20.87½ cents.

# The Week in Trade

Prices When Quoted Are Those Reported at the Opening of Business on Monday of This Week for Points West of the Mississippi River and on Tuesday for All Eastern Points

HEAVY snows and the colder weather have delayed deliveries in the New England and Western States, with the result that wiring supplies, especially conduit, are noticeably lower than three weeks ago. Some labor demands are causing delays in new construction, which in turn may affect the now healthy demand for all commodities entering into these projects. The rising price of copper has already caused several upward revisions in quotations for wire. The influenza epidemics in large cities are causing an increase in the demand for open-air heaters and heating pads. Other appliances, noticeably flatirons, toasters, cooking appliances and small ranges, are receiving more attention in orders from the dealers. Porcelain, poles and pole-line hardware are selling in better volume in view of the contemplated expansions and repairs to be made by central stations, telephone companies and railways in the next few months. Second-hand-motor dealers are said to be prospering, while much activity is noted among the manufacturers of smaller sizes of motors for spring deliveries to fan makers, who anticipate a very active season. Meters also have taken on increased interest. Much competition prevails among the commercial-fixture manufacturers who are carrying on extensive sales campaigns and who are doing some price cutting. Radio dealers report buying during the past few weeks as decidedly active.

**Boston** Business continues to improve, although it is handicapped severely by railroad conditions and extreme winter weather. Deliveries are giving much trouble all over New England. Central-station outputs continue to grow and appliance sales are healthy. Building and engineering contracts in New England for the week ended Feb. 13 totaled $3,900,300 against $1,882,100 a year ago. Labor shows a tendency to demand concessions unfavorable to business expansion in the building trades, but conditions are not yet acute. Jobbers report great activity in inquiries and stocks are rather spotty. In some sizes galvanized rigid conduit was practically unobtainable here Monday. More interest is being shown in electric vehicles for lighter delivery service. Sales of motor and control equipment for industrial power applications are better than for many months. Some fixture purchases are delayed by cold weather.

**New York** Jobbers and manufacturers' agents report a steady demand for all central-station equipment in view of repairs and extensions which will start when the warmer weather sets in. Increases in copper prices has caused some strengthening in the wiring market, while some stocks are lowered due to poor transportation and shortages of raw materials. Lamps are moving in slower volume than one week ago. Commercial-fixture demand is somewhat slower. Motors in the larger sizes are moving in quick succession from the second-hand dealers' stocks. A steady call for heating appliances and electric warmers is reported following the cold days of last week. Collections are reported to be improving.

**Baltimore** A general slight tendency to increased business in various commodities is reported by the dealers, which, although encouraging, is not taken too optimistically. Most of the houses still remain well stocked, although not overstocked. There are several big electrical installations to be made in this section at the beginning of spring. On the whole, the prospects at the present time are encouraging. The contractors as well as the jobbers are looking for a large spring business in school buildings and residences. The market as a whole is firm.

**Atlanta** Reports indicate very little change in general conditions since last week. Deliveries are slow, but there have been no shortages as a result with the exception of conduit. Prices of conduit and wire continue to climb. All jobbers report business as satisfactory. One of the largest jobbers has placed orders on manufacturer for fan supplies 50 per cent in excess of last year's orders, and, judging from the number of fan contracts signed for future delivery, this will be the biggest season ever seen in fans. Business in storage batteries continues good. This is a reflection of the improved financial condition and mental attitude of customers in this section, many cars that have been in storage now being operated again. The outlook in this line is particularly bright and prices are generally on the increase.

**Pittsburgh** Business generally is good. The confidence of the jobbers is being restored, consequently stock orders for standard material are becoming more prevalent. This air of confidence is also being manifested among the dealers to a great extent. It is estimated that the city of Pittsburgh is behind two and one-half years in its building program, consequently a continued increase in business due to building activities is looked for. In the outlying territories one of the large central stations is putting on an extensive house-wiring campaign which is bringing excellent results. The contracts for wiring are in turn being turned over to various contractor-dealers in the towns in which this particular station operates. This is producing a spirit of harmony and co-operation between the central stations and contractor-dealers.

**Cleveland** Little change has occurred in the market during the past week. Armored cable is in strong demand and so is conduit, with ample stocks and fair deliveries. Commercial fixtures are slower, but firm prices prevail. Although motor sales show no perceptible decrease the demand lessened slightly with firm prices. Storage batteries are active and a few jobbers report desirable orders. Farm-lighting plants are being pushed by advertising, but they are being met with rather indifferent results. Building operations are extensive, despite a recently adopted conservative policy of banks and mortgage brokers, and plans for spring include many large projects. Controversy over a gas franchise and colder weather have promoted the sale of heating appliances to a degree and central-station power sales are in greater volume. Industrial-equipment jobbers are busy. A shortage in radio tubes is reported. Transportation is becoming less difficult. Collections are in better shape.

**St. Paul-Minneapolis** Business is somewhat unsettled. Lighter orders by dealers show uncertainty compared with the confidence of a week ago. Buying for future use on rising market is slowing up. Cold weather and heavy snows are slowing up construction. Retail buying is poor. However, in spite of upset conditions, business is 50 per cent ahead of last year and spring prospects are good. January business is better than February.

**St. Louis** A feeling of optimism pervades all branches of the industry since the passage of the $87,000,000 bond issue for civic improvements. The recent cold snap, followed by melting snow and rain, has caused an unusual amount of sickness, resulting in a large demand for heaters and heating pads at a time of year when the sale of these appliances might normally be expected to decrease. Electrical jobbers report continued good business. The shortage in conduit continues, that in enameled conduit being acute. The market for motors continues active with low stocks. Radio buying continues active. Dealers in electrical refrigerating equipment report sales greater than for the corresponding period last year with bright prospects for the spring. Prices show an upward trend and collections are good.

**Denver** Upward trend on copper prices is showing reaction in house wiring, although several cars of wire recently received have been sold at less than manufacturers' present price because of conditions under which they were purchased. Volume of sales reported from southern part of state

# Demand, Supply and Price Trend of Nineteen Commodities as Sold in Sixteen Cities

Explanation:
Demand: Steady, Slow or Active
Supply: Normal, Low or High
Price Trend: Firm, Decreasing or Increasing

Next Week Reports will include Conduit Boxes, Signal Apparatus and Rectifiers

and New Mexico indicates more rapid improvement than in northern sections. Country banks are becoming more liberal with credit, although collections from electrical contractors have not improved in the same degree. New construction has been hampered by a few days of cold weather.

## Salt Lake City

A slight revival of interest in radio is reported with prospects of fair activity in the spring. Indications of big construction activity in railway extension, electrical lines and business blocks look brighter as spring approaches. Contractor-dealers are already finding steady employment with new installations and a fair market for electrical materials.

## Portland-Seattle

One of the heaviest snowstorms in recent years visited the Northwest last week, creating considerable damage to electric lines in the Puget Sound District. Business was slowed up for a couple of days, but the week's volume was not materially changed. Sales continue active and prospects for a good year are most favorable. January jobbing business was about 15 per cent and central-station generation about 20 per cent ahead of a year ago. Although the lumber output is above normal, new business continues to lead production by at least 25 per cent. Copper is stiffening. The rather striking drop in porcelain knobs and tubes reported last week was apparently due to a temporarily competitive condition existing in this locality.

## San Francisco

Retail store business is improving. Building was slackened somewhat during storms early in the month, but present fine weather has brought it back toward the peak. Special attention is being paid to industrial exploitation in all large cities, and the steady though unobtrusive growth of the past ten years is now suddenly expanding very noticeably. Collections are still averaging somewhat over sixty days, but early improvement is expected. Stocks in general are well maintained, and there are few shortages because of the steady and well-assorted demand. Water shipments are increasing.

Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

## Westinghouse Plans Large Chicago Warehouse

The Westinghouse Electric & Manufacturing Company is to erect a seven-story manufacturing and warehousing plant, 500 ft. x 240 ft., on West Pershing Road and Leavitt Street, Chicago. This construction work will be the largest in the central district since the erection of the four government warehouses in 1918. Besides the facilities for manufacturing switchboard panels and recharging equipment, this new building will serve as central and local distribution offices and eventually the sales offices for the Western territory. The building will consist of four units. The first, now under construction, will front 240 ft. on Pershing Road and extend back 130 ft. The concrete for the fifth floor is now being poured. Four thousand square feet of the second unit will also be built at the present time, although the entire second unit is not expected to be completed until 1924. This building will contain 960,000 sq.ft.

## Ohio Brass Appointments

The Ohio Brass Company, Mansfield, Ohio, manufacturer of high-voltage porcelain insulators, announces that Thomas Jones, formerly with the Electric Appliance Company, has joined its sales force and will make his headquarters in Dallas, Tex. The company also announces that L. M. Keating, who has been connected with its home sales office for a number of years, has been transferred to outside sales and will have his headquarters in El Paso, Tex.

## Correction of Error in Incandescent Lamp Suit Story

In the Feb. 17 issue of the ELECTRICAL WORLD, page 425, a statement appeared to the effect that the General Electric Company had been granted a preliminary injunction against P. R. Mallory & Company, Inc., Port Chester, N. Y., manufacturers of tungsten wire, and the Save Electric Corporation, Brooklyn, N. Y., manufacturer of incandescent lamps, which would have the effect of "preventing defendants from continuing the manufacture and sale of their products pending the final outcome of the litigation." It is found that this information was erroneous.

The facts are that the injunction under the Just and Hanaman patent was suspended ninety days as to both companies pending trial of the case, and that the injunction under the Langmuir patent was suspended as to the Save Electric Corporation pending the trial of the case in so far as relates to certain contracts with the city of Chicago and the state and city of New York.

As to P. R. Mallory & Company, Inc., furthermore, the proceedings have no effect upon any of its foreign sales or any of its business in contacts and other products. P. R. Mallory is restrained only from selling alleged tungsten wire for use in this country in the manufacture of the so-called "gas-filled incandescent electric lamps," which would constitute an infringement of claims 4, 5, 12 and 13 of the Langmuir patent.

## Detweiler and Bell Incorporate as Manufacturers' Agents

Paul G. Detweiler and Stewart S. Bell have filed papers of incorporation in Connecticut as the Detweiler-Bell Company, manufacturers' agents, and will begin business March 1 in the Liberty Building, New Haven, Conn. This company will sell its products through jobbers.

Stewart Bell operated one of the first central stations in Massachusetts. He has been connected with the Westinghouse Electric & Manufacturing Company at Boston, with Stuart-Howland Company, Boston, and lately in Boston for the Moloney Electric Company. Paul G. Detweiler was district manager for the Franklin Electric Manufacturing Company at Hartford, Conn., and manager of lamp sales and illuminating engineering for the firm of Hessel & Hoppen Company, New Haven, Conn.

# To Co-operate in Building Locomotives

Announcement has been made that the General Electric Company and the American Locomotive Company have effected an arrangement to co-ordinate their effort in the design and manufacture of electric locomotives for use on steam and electric railways.

The co-operation of the engineering and manufacturing facilities of these companies will doubtless result in improvements in design and construction and economies in manufacture and render improved service to railway companies. This arrangement between the two companies has been brought about in a large measure by the increased interest and business in railway electrification in the United States and abroad, particularly within the last year, and in anticipation of a large volume of work in the immediate future. A recent survey of the locomotive department of the Erie Works of the General Electric Company indicates that at present there are a larger number of orders from different customers than has been the case at any time since the beginning of the World War. Foreign business appears even more active than domestic. Spain, France, Chile, Japan, Mexico and South Africa are engaged in extensive projects, while other countries, including Italy and Great Britain, are seriously considering large-scale electrifications.

For a number of years the American Locomotive Company and the General Electric Company have collaborated in the development of electric locomotives. The Locomotive company has applied its knowledge and experience in the locomotive building art particularly to the design of the mechanical elements in the fabrication of which its manufacturing facilities were utilized, while the knowledge and experience of the General Electric Company were applied to the design of the electrical elements.

It is the satisfactory results of this collaboration which has led to the more formal relationship just announced, both companies believing that progress in the art can be most effectively assured by such means. The arrangement relates only to co-operation in design, development and manufacture and does not comprehend any financial relationships between the two companies.

## Edward Miller Company Bought by Rex Cole and Associates

The well-known fixture firm of Edward Miller & Company, Meriden, Conn., has been purchased by Rex J. Cole and associates, and with it will be merged the Duplexalite Corporation and the Duplex Lighting Works of the General Electric Company, which will thus be discontinued as separate companies, the combined business being operated under the name of Edward Miller & Company of Meriden, Conn., with Rex J. Cole as president and Max Schwarz as vice-president and general manager.

Edward Miller, Jr., will continue as chairman of the board, and other officers are: Vice-presidents, Guy P. Norton and I. B. Miller; treasurer, Samuel McNabb; secretary, Hewitt Warburton; assistant secretary, L. A. Frost.

The Edward Miller company was founded in 1844, and in the early days manufactured oil lamps, later adding gas-lighting products, and finally entering the electrical field, where it has become one of the large manufacturers of portable lamps and lighting fixtures.

The Duplexalite offices in New York City will be discontinued and headquarters moved to Meriden. Meanwhile the Edward Miller offices on Park Place, New York, will be enlarged, and other branch offices will be maintained in Chicago, Cleveland and San Francisco.

## Foreign Trade Notes

ELECTRICITY FOR EAST FLANDERS, BELGIUM.—Plans are being prepared by the commission recently appointed by the Provincial Council of East Flanders whereby the devastated districts will be supplied with electricity by next winter. Power will be supplied by the province and distributed by the communes to the consumers. Communes not located in the devasted regions will also be served.

PROPOSED ELECTRIC SYSTEM IN FRANCE.—Application for a concession to supply electricity for light and power in twenty-one communes in the Syndicat Intercommunal de Méligny-le-Grand, Department of the Meuse, has been made by the Compagnie Lorraine d'Electricité, Nancy. The Société Co-operative Agricole d'Electricité de la Region d'Hattencourt has petitioned for a concession to furnish electricity in twenty-three rural communes in the Hattencourt district, Somme Department. Application has also been made by another co-operative agricultural association for authority to supply electricity to thirty-two communes in the district of Montigny-sur-Halluce, in the same department. Steps which have been taken to develop the water power of the River Tinée in the Canton of Nice having proved successful, the Tinée Hydraulic Commission has reported favorably on the projects to develop the water power of the Saint-Etienne Laos, Bancairon and Corbaisse Falls. The work will be done by the Société de l'Energie Electrique du Littoral Mediterranéen. The scheme proposed by Lucien Neu and Louis Schowb, consulting engineers, Enghien, to develop 2,500 kw. on the River Doube for the city of Aesançon, to cost about 5,000,000 francs, has been adopted.

APPLICATION FOR CONCESSION TO SUPPLY ELECTRICITY IN THE YONNE AND NIEVRE DISTRICTS, FRANCE.—Application has been made by the Société d'Etudes des Chutes de la Cure et des Chemins de Fer Electriques de l'Yonne (Cure Falls and Yonne railway schemes) for a concession for the distribution of electricity for public service in the Yonne and Nièvre Departments. The concession includes the four departments of the Yonne, Nièvre, Côte-d'Or and Haute Marne. A power plant of 6,000 kw. capacity has already been built at Langres, and the concession includes the connection of this station with those of the Cure by a 60,000-volt transmission line. The cost of the project is estimated at 23,300,000 francs. Under the terms of the concession a minimum of 35 km. of railway line must be constructed within five years and 150 km. within ten years. As a result of these plans applications for state concessions have already been placed for a 20,000-volt transmission line from Sens to Auxerre by two companies, and for another extending from Langres to Chatillon-sur-Seine, Montbard, Cure and Auxerre. It has been decided to adopt the three-phase system.

## Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number.

Purchase is desired in France (No. 5,422) of electric automobile trucks.

Agency and purchase is desired in Italy (No. 5,481) for electric recording pyrometers, elapsed-time recorders, electric time switches, electric impulse clocks, water-level recorders and electric signal systems.

An agency is desired in Norway (No. 5,490) for cables and wires for power plants and electrical intallations.

WATER-TUBE BOILERS FOR POWER PLANT, SYDNEY, AUSTRALIA.—Tenders will be received until May 23 by the Railway Commissioners for eight water-tube boilers with accessories for the White Bay power house, Sydney, for the New South Wales government railways and tramways (Specification 575).

TELEPHONE EQUIPMENT FOR AUSTRALIA.—Tenders will be received by the Postmaster-General's Department, Melbourne, Australia, until April 10 for 686 tons of bronze wire and 500,000 paper jointing sleeves; also until April 17 for 595 timing clocks for trunk calls and 400,000 copper jointing sleeves. Tenders will be received by the Postmaster-General's Department, Adelaide, Australia, until April 18 for telephone apparatus.

ELECTRIC EQUIPMENT FOR PUMPING PLANT FOR BRISBANE, AUSTRALIA.—Tenders will be received by the Metropolitan Water and Sewerage Board, Brisbane, Australia, until June 26 for equipment for pumping plant, including a 140-kw., 440-volt direct-current electric generating unit.

TELEPHONE AND TELEGRAPH MATERIAL FOR TASMANIA. — Tenders will be received by the Postmaster-General's Department, Hobart, Tasmania, until April 9 for telegraph and telephone materials, including magneto bells, timing clocks, detectors, mouthpieces, lamps, etc.

PROPOSED EXTENSIONS TO THE MUNICIPAL ELECTRIC PLANT AT SHANGHAI, CHINA. — Plans are under consideration, according to *Commerce Reports*, to increase the output of the municipal electric plant at Shanghai, China, to 180,000 hp. The present capacity of the plant is said to be about 105,000 hp.

## New Apparatus and Publications

ELECTRIC REFRIGERATOR. — A new household electric refrigerator outfit has been placed on the market by the Motorfrigerator Company, Lansdale, Pa.

HOUSEHOLD CABINET REFRIGERATOR.—The Universe Corporation, 341 East Ohio Street, Chicago, has placed on the market a new electric refrigerator, known as "Polaris."

PLURAL PLUG.—The Benjamin Electric Manufacturing Company, 847 West Jackson Boulevard, Chicago, has brought out a new edition of the No. 92 original two-way plug, known as the "One-to-two" plug.

AUTOMATIC TIME SWITCH.—An automatic time switch for henneries, known as the "Cackle" time switch, is being distributed by A. Hallberg, 73 Murray Street, New York City.

ELECTRIC FAN.—A new electric fan for household use has been placed on the market by the Kendrick & Davis Company, Lebanon, N. H.

ELECTRIC APPLE-PARING MACHINE. —An electric motor-driven apple paring and coring machine for hotels and restaurant kitchens has been placed on the market by the Goodell Company, Antrim, N. H.

ELECTRIC WAXER SCRUBBER AND POLISHER. — A new machine has been developed by the Kent Company, Inc., Rome, N. Y., for sandpapering, scrubbing, waxing and polishing floors by electricity.

TIME SWITCH WITH CLOCK. — The Tork Company, 8 West Fortieth Street, New York City, has placed on the market a new time switch with clock, known as the "Tork Clock."

ELECTRIC WASHING MACHINE. — A new wringerless washing machine has been placed on the market by the Savage Arms Corporation, Utica, N. Y.

ELECTRIC HEATING PAD.—An electric heating pad, known as "Blue Bird," has been developed by the Charles Electric Garments Company, 1614 West Washington Street, Los Angeles, Cal.

FRACTIONAL-HORSEPOWER MOTORS. —A new line of fractional-horsepower motors of the split-phase type has recently been developed by the Robbins & Myers Company, Springfield, Ohio.

ELECTRIC REFRIGERATING MACHINE.—The Coldak Company, Springfield, Mass., is distributing a booklet in which it describes the new "Coldak" household electric refrigerating machine. This machine can be applied to any existing ice box.

## New Incorporations

THE LINDALE (TEX.) LIGHT & POWER COMPANY has been incorporated with a capital stock of $5,000 by R. F. Tarbrough, W. R. Eason and others.

THE APPOMATTOX (VA.) LIGHT & POWER COMPANY has been chartered with a capital stock of $25,000. The officers are C. A. Hancock, president, and C. W. Smith, secretary.

THE CONSOLIDATED POWER & LIGHT COMPANY, Huntington, W. Va., has been incorporated by C. L. S. Tingley, Walter W. Perkins and Henry P. Megaree, Philadelphia; W. R. Power and T. M. Hays, Huntington. The company is capitalized at $5,000,000 and proposes to take over the holdings of Consolidated Light, Heat & Power Company.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

MILO, ME. — Arrangements have been made whereby the transmission lines of the Milo Electric Light & Power Company and the Central Maine Power Company, Augusta, will be permanently connected for the purpose of an interchange of power.

PORTLAND, ME. — The Cumberland County Power & Light Company is reported to be considering doubling the capacity of its new steam-power plant at Knightville.

BOSTON, MASS.—Bids will be received by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., until March 6, for 15,000 ft. of flexible conductor lighting and power wire, for the local navy yard (Schedule 523).

CAMBRIDGE, MASS.—Power equipment will be installed by the National Biscuit Company, Tenth Avenue, New York, in connection with its proposed local baking plant, to cost about $250,000.

NEW BEDFORD, MASS.—The installation of ornamental lamps on Borden, Anthony and Grove Streets is under consideration by the committee on street lights. The cost is estimated at $2,448.

WORCESTER, MASS.—A power plant will be built in connection with an addition to the Worcester Hahnemann Hospital, 261 Lincoln Street, to cost about $300,000. Kendall, Taylor & Company, 142 Berkley Street, Boston, are architects.

BRIDGEPORT, CONN.—The City Council is considering the installation of an ornamental lighting system on Broad Street and Stratford Avenue.

MERIDEN, CONN.—The local car barns and shops of the Connecticut Company were recently destroyed by fire, causing a loss of about $150,000.

NEW BRITAIN, CONN. — The question of improving the street-lighting system, especially in the outlying sections of the city, is under consideration by the Board of Public Works.

ROCKVILLE, CONN.—The Public Utilities Commission has instructed the Rockville-Willimantic Lighting Company to extend its electric lighting service through the villages of Forestville, West Stafford and Orcutts, the work to be completed by June 15.

TORRINGTON, CONN.—A petition has been presented to the Borough Council by the merchants and property owners for the installation of an ornamental lighting system in the business section of East Main, Water and South Main Streets.

WATERBURY, CONN. — Arrangements are being made by the Connecticut Light & Power Company for the erection of about 75 miles of high-tension transmission line for the distribution of electricity generated at its new plant, which is being constructed at Devon on the Housatonic River.

## Middle Atlantic States

ALBANY, N. Y.—Electric power equipment will be installed in the addition to the plant of the Simmons Machine Company, 985 Broadway, to cost about $250,000.

BUFFALO, N. Y.—A luminous magnetite street-lighting system will be installed on Fillmore Avenue from Seneca to Best Street.

BUFFALO, N. Y.—The City Council has appropriated $10,000 for the installation of overhead electric traffic controls for use in regulating the traffic on Main Street.

ITHACA, N. Y.—The Associated Gas & Electric Company, operating the Ithaca Gas & Electric Company and other utility properties, contemplates increasing its capital from 150,000 shares to 210,000 shares, no par value, the proceeds to be used for extensions and improvements.

NEW YORK, N. Y.—The National Biscuit Company, Tenth Avenue and Fifteenth Street, plans to build a power house to cost about $150,000.

NEW YORK, N. Y.—Bids will be received by the Superintendent of Light Houses, Staten Island, until Feb. 26, for six switchboards (Proposal 14,220).

NIAGARA FALLS, N. Y.—G. A. Strain, receiver for the Niagara Falls Gas & Electric Company, is planning extensions and improvements.

POTSDAM, N. Y.—A power plant will be built in connection with the proposed paper mill to be built by a company now being organized by Hollis W. Martin, Norwood, N. Y. It will cost about $110,000. T. L. Tomlines, City Bank Building, Syracuse, is engineer.

WATERTOWN, N. Y.—The proposal to issue $365,000 in bonds to develop the water power at Delano Falls for municipal purposes will be submitted to the voters on Feb. 24.

DELAWARE, N. J.—The Metropolitan-Edison Company is preparing plans for a hydro-electric power plant, to cost about $750,000.

SUMMIT, N. J.—Bids will be received by the Board of Education until March 5 for electric work and equipment in the proposed addition to the Washington School, North Summit. P. W. Lyall is secretary of the board.

DRUMS, PA.—The Pennsylvania Power & Light Company will build a transmission line from Kis-Lyn to Drums, also from White Haven to Mountain Top.

KITTANNING, PA. — Plans are being drawn for a power house at the local Community Hospital, in connection with a new hospital building to cost $250,000. Crow, Lewis & Wick, 200 Fifth Avenue, New York, are architects.

NEW CASTLE, PA.—The Carnegie Steel Company, Pittsburgh, will build an addition to its local power house, including improvements in the present plant, to cost about $200,000.

OIL CITY, PA. — The Penn-American Refining Company will build a power plant at its local works, to cost $95,000. The Rust Engineering Company, 311 Ross Street, Pittsburgh, is engineer.

SHAMOKIN, PA. — The Pennsylvania Power & Light Company contemplates extending its service to Gowen City in the spring.

ZELIENOPLE, PA.—Electrically operated pumping machinery and other motor-driven equipment will be installed in connection with the proposed water filtration plant, to cost about $150,000. Hudson & Myron, Wabash Building, Pittsburgh, are engineers.

HUNTINGTON, W. VA.—The Consolidated Power & Light Company, recently organized to take over property of the Consolidated Light, Heat & Power Company, plans extensions to the system.

WASHINGTON, D. C.—Bids will be received by the Supervising Architect, Treasury Department, until March 2 for the furnishing and installing electric lighting fixtures in the post offices at Apalachicola, Fla.; Charleston, W. Va.; Eureka, Utah; Front Royal, Va.; Vinton, Iowa, and the United States post office and court house at Buffalo, N. Y.

## North Central States

BAY CITY, MICH.—Bids will be received by the Water Commissioners until March 5 for electric and power wiring, heating and ventilating, etc., for the waterworks plant, to cost about $150,000. Frazier, Sheal & Ellms, B. F. Keith Building, Cleveland, are engineers.

DETROIT, MICH. — The Detroit-Edison Company contemplates the erection of a new steel-tower transmission line.

LIMA, OHIO. — The Lima Locomotive Works contemplates rebuilding the portion of its power plant, recently destroyed by fire, with a loss of about $30,000.

MARIETTA, OHIO.—Work has started on the installation of a new turbo-generator and boilers in the Riverside plant of the Monongahela Power & Traction Company.

CHAMPAIGN, ILL.—Improvements are contemplated by the Urbana & Champaign Railway, Gas & Electric Company during 1923, to cost about $40,000.

BIRON, WIS.—Failing to make satisfactory arrangements with the city authorities of Stevens Point, the Consolidated Water Power & Paper Company has decided to locate in Biron. It will erect a two-story building, oxer 400 ft. long, to house its plant. Plenty of power is available here, but electrical equipment will be necessary to connect the hydro-electric units with the new equipment.

COON VALLEY, WIS.—The Coon Valley Electric Company plans to rebuild its entire lighting system, including changing the service from direct to alternating current. New equipment, including switchboard, motors, transformers and generator, will be required.

DOUSMAN, WIS.—The plant and holdings of the Dousman Electric Light & Power Company have been purchased by the Milwaukee Electric Railway & Light Company. Extensions and improvements, it is understood, will be made to the local system by the purchasing company.

EAU CLAIRE, WIS. — The Wisconsin-Minnesota Light & Power Company contemplates the purchase of heavy copper wire (to cost about $45,000) to be used on its high-tension transmission line between the hydro-electric plant at Wissota and Stillwater, Minn. It is proposed to increase the wires on the towers from four to seven.

EVANSVILLE, WIS.—The Council has decided to install an ornamental lighting system, consisting of thirty-six standards, during the coming year.

MILWAUKEE, WIS. — Preparations are being made by the Milwaukee Electric Railway & Light Company for the erection of a high-tension transmission line between Vernon and Big Bend.

MILWAUKEE, WIS.—Backes & Pfaller, 217 West Water Street, architects and engineers, have been engaged to prepare plans for a five-story hospital addition, a boiler house and power plant and other buildings, for the Misericordia Hospital, 2224 Chestnut Street. New equipment, including boilers, engine, generators, ice machinery, etc., will be required. The cost is estimated at $165,000.

ONTARIO, WIS.—Negotiations are under way between the Ontario Electric Light & Milling Company and the City Council for extension to the street-lighting system.

WAUSAU, WIS.—The committee on lighting has recommended to the City Council the installation of street lamps at numerous intersections in the city.

LITTLE FALLS, MINN. — The Little Falls Water Power Company contemplates the erection of a transmission line from Lastrup to Onamia, Wahkon and Isle.

MINNEAPOLIS, MINN.—The South Minnesota Gas & Electric Company has issued $1,750,000 in bonds, part of the proceeds to be used for extensions and improvements.

RED WING, MINN.—Bids, it is reported, will soon be asked for the installation of a municipal electric power plant, to cost about $350,000.

MUSCATINE, IOWA — Bids, it is reported, will be called in March for the construction of a municipal electric power plant. Arthur L. Mullergren, Firestone Building, Kansas City, Mo., is engineer.

SIOUX CITY, IOWA.—The Sioux City Gas & Electric Company is planning to place all wires in the downtown business section of the city underground. Arrangements are also being made by the company to supply electricity in about seventy-five towns in northwestern Iowa. The erection of the transmission lines to furnish the service is already under way.

PLEASANT HILL, MO.—The West Missouri Power Company contemplates extensions and improvements to its system, including the installation of new equipment. The company recently increased its capital from $750,000 to $1,400,000.

ST. JOSEPH, MO. — Electric power equipment will be installed at the proposed woodworking plant of the Collier-Adams Manufacturing Company, Fourth Street and Mitchell Avenue, to cost about $100,000.

ST. LOUIS, MO.—Bonds to the amount of $8,000,000 has been voted for the installation of a street-lighting system in all parts of the city; also $1,000,000 for a municipal electric power plant and mechanical building for civic service. W. Frank Carter is chairman of the committee on civic needs.

ST. LOUIS, MO.—Contracts will soon be awarded for prism lamps and concrete standards on Watson Road and Clara Avenue, to cost about $35,000. R. Toensfeldt is city engineer.

FREDONIA, KAN.—An election will be held on Feb. 27 to vote on the proposal to issue $150,000 in bonds to establish a municipal electric light and power plant. C. R. Schiek is engineer.

KANORADO, KAN. — Bonds to the amount of $25,000 have been voted for the installation of a local electric distributing system and a transmission line. W. B. Rollins & Company, Railway Exchange Building, Kansas City, Mo., are engineers.

LEAVENWORTH, KAN.—Elecric power equipment will be installed at the local plant of the Bonner Portland Cement Company, Kansas City, Mo., in connection with extensions and improvements, to cost, about $1,500,000.

LEAVENWORTH, KAN.—A power house to cost about $35,000 will be erected at the new public school on Third Avenue, to cost about $110,000. The Board of Education is in charge.

WASHINGTON, KAN.—The installation of an ornamental lighting system in the business district is under consideration.

WICHITA, KAN.—The Derby Refining Company will install electric power equipment in connection with additions to its local oil refinery, to cost about $300,000.

## Southern States

CLINTON, N. C.—The Tidewater Power Company, Wilmington, will build a transmission system to Clinton, by way of Warsaw, about 68 miles, to cost about $130,000.

MOUNT AIRY, N. C. — Electric power equipment will be installed in the proposed ice-manufacturing and refrigerating plant to be erected by the Carolina-Virginia Growers' Association. J. B. Sparger is president.

MURPHY, N. C. — The North Carolina Iron & Mining Company, Andrews, will install electric power and mechanical equipment for a new washing and crushing plant at its properties.

ROUGEMONT, N. C.—W. A. Carver is making inquiries for a generator, 75 hp. to 100 hp.

GREAT FALLS, S. C. — The Republic Cotton Mills, Inc., will build a power house, 42 ft. x 47 ft., in connection with a new mill, to cost about $150,000. J. E. Sirrine & Company, Greenville, are engineers.

MOLINO, FLA. — The Jacobi Lumber Company contemplates rebuilding its lumber works, including planing mill and power house, recently destroyed by fire, causing a loss of about $200,000.

BRISTOL, TENN.—A bill has been presented to the State Legislature by Senator D. A. Barger authorizing the city of Bristol to issue $500,000 in bonds for the purpose of establishing a municipal electric light plant.

KNOXVILLE, TENN. — The Cherokee Spinning Company will install a substation at its proposed mill to cost about $400,000.

NASHVILLE, TENN. — The Hermitage Portland Cement Company, Chattanooga, will build a power house at its proposed local plant, to cost about $500,000.

PARIS, TENN.—Extensions and improvements to the municipal electric light and water plant, to cost about $100,000, are under consideration. W. J. Holman is manager.

ATHENS, ALA.—Electric power equipment will be installed in the ice-manufacturing and refrigerating plant to be built by the Athens Ice & Coal Company, for which plans have been prepared.

COLLINSVILLE, ALA. — The Collinsville Light & Power Company contemplates extensions to its plant, including the installation of new equipment.

SAMSON, ALA.—The municipal electric light and water plant has been purchased by the Pea River Power Company, Troy. The new owners will take over the property at once and will erect a transmission line from Elba to supply electricity to operate the local system.

OXFORD, MISS.—Bids will be received by the Board of Aldermen and Mayor until March 15 for an engine, generator and switchboard equipment for the municipal electric and water plant. Proposals will be received for either oil-engine or steam-engine equipment. T. M. Early is superintendent of water and light plant.

BEAUMONT, TEX.—The Beaumont Sash & Door Company will install electric power equipment in connection with its proposed local plant, to cost about $65,000.

CORPUS CHRISTI, TEX.—Plans are under consideration for the installation of a municipal underground conduit system.

DALLAS, TEX.—Bids will be asked at once for the installation of an ornamental lighting system on Jefferson Street, Oak Cliff section.

## Pacific and Mountain States

EPHRATA, WASH. — The Washington Water Power Company contemplates the election of a transmission line to Quincy, about 18 miles.

OLYMPIA, WASH. — A franchise has been granted to Charles G. Hawson, Olympia, for the erection of a transmission line in the Pleasant Glade district for commercial light and power service.

SEATTLE, WASH.—Bids will be received by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., until March 13, for 7,300 ft. of telephone cable for use at the local navy yard (Schedule 521); bids will also be received for 3,600 ft. of fiber conduit and 2,200 ft. wood conduit (Schedule 522).

SEATTLE, WASH.—Bids will be received by the Bureau of Yards and Docks, Navy Department, Washington, D. C., until March 14, for one electric traveling crane for use at the local navy yard (Specification 4755).

WENATCHEE, WASH.—The Wenatchee Placer Gold Mining Company contemplates the installation of a power plant at its properties.

ASTORIA, ORE.—The Union Oil Company, San Francisco, Cal., will build a power house in connection with its proposed local oil plant, to cost about $500,000.

LOS ANGELES, CAL.—Ordinances have been approved providing for the installation of street-lighting systems on Pacific Avenue, Seventh and Fourteenth Streets, San Pedro district.

LOS ANGELES, CAL.—The installation of an ornamental lighting system on Arden Boulevard and on El Centro Avenue is under consideration.

LOS ANGELES, CAL.—A power house will be erected by the Mexican Petroleum Company, 120 Broadway, New York, in connection with its proposed refining plant in the San Pedro section, to cost about $6,000,000.

LOS ANGELES, CAL.—Ordinances have been approved for the installation of ornamental lighting systems on Canal Avenue, from Anaheim to D Street, and on Washington Street, from Hobart Boulevard to Eighth Avenue.

PITTSBURG, CAL. — Electric power equipment will be installed in the proposed addition to be erected by the Columbia Steel Corporation, consisting of five buildings, to cost about $200,000.

SAN DIEGO, CAL.—Plans for the proposed cotton mill to be erected in San Diego by the California-Pacific Textiles, Inc., to cost about $600,000, include a power plant. W. A. Golden is president.

VENICE, CAL.—The Council is considering the installation of an electrical distributing system, to cost about $100,000.

ASPEN, COL.—The Belle Marie Mining & Milling Company is planning to build a new plant in the spring, including mining and mill buildings, and power house, to cost about $275,000. A. J. Petelinz, 426 Grand Avenue, Milwaukee, is architect.

CANON CITY, COL.—Improvements will be made to the boiler room of the local plant of the Southern Colorado Power Company, to cost about $20,000.

DENVER, COL.—Bids will be received at the office of the United States Reclamation Service, Denver, until March 13, for one 1,000 kva., vertical alternating-current generator, complete with exciter; four 333 kva., single-phase, self-cooled transformers; three 10 kva. single-phase, self-cooled transformers; switching apparatus, etc.

ROSWELL, N. M.—The City Council is considering the purchase of the plant of the Roswell Public Service Company, to be owned and operated by the municipality.

## Canada

VANCOUVER, B. C.—The British Columbia Electric Company has purchased a site for an addition to power plant of its subsidiary, to cost about $90,000.

PETERBORO, ONT. — The Hydro-Electric Power Commission of Ontario is preparing plans for the development of the water powers of dams Nos. 8 and 9 on the Trent River, which will be used to augment the power supply of Peterboro.

STOUFFVILLE, ONT.—A committee has been appointed to negotiate with the Hydro-Electric Power Commission of Ontario with a view of securing hydro-electric service for this village. A transmission line (11 miles long) to connect with the Yonge Street line would have to be erected.

TIMMINS, ONT.—An agreement has been reached between the Ontario government and the Hollinger Mining Corporation whereby the latter will begin work on the construction of a hydro-electric development at Island Falls. The plans provide for a development of 16,000 hp. at a cost of about $3,000,000.

QUEBEC, QUE.—An additional power development of 7,500 hp. is reported to be under consideration by Price Brothers & Company, Ltd.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued Feb. 6, 1923)

1,444,425. ELECTRIC REGULATOR FOR INTERNAL-COMBUSTION ENGINES; H. Ogden, Westcliff-on-Sea, England. App. filed May 22, 1922. Control of engine driving welding generator prevents excessive sudden loads.

1,444,434. INSULATOR SUPPORTING PIN; L. Steinberger, Brooklyn, N. Y. App. filed Nov. 6, 1918. Cross-arm pin having coiled spring for screwing into insulator.

1,444,438. ELECTRODE STRUCTURE; W. C. White, Schenectady, N. Y. App. filed Aug. 7, 1918. Construction of grids for electron discharge relays or amplifiers of pliotron type.

1,444,454. LAMP SOCKET; W. L. Brooks, Schenectady, N. Y. App. filed Oct. 27, 1920. When lamp is withdrawn circuit is automatically closed through socket.

1,444,458. DYNAMO-ELECTRIC MACHINE; V. H. Greisser, Spokane, Wash. App. filed Oct. 21, 1921. Method of ventilation.

1,444,494. SILENCER FOR TELEPHONES; S. T. Cohane, Hartford, Conn. App. filed Feb. 15, 1922. Attachment for transmitter to cut out extraneous sounds.

1,444,495. ELECTRIC MOTOR; C. Z. Coleman, San Francisco, Cal. App. filed Oct. 28, 1921. Laminated core rotor.

1,444,524. MAGNETIZING DEVICE; E. S. Pridham and P. L. Jensen, Oakland, Cal. App. filed April 28, 1920. Device for making permanent magnets without breaking magnetic circuit.

1,444,555. TELEGRAPH RELAY; C. J. Rogers, Morris, Okla. App. filed Feb. 7, 1920. Differentially wound transmitting coils for use on "leaky" lines.

1,444,561. ELECTRIC BATTERY HEATER; J. E. Schraeder, Crookston, Minn. App. filed Jan. 12, 1922. Device for heating storage batteries before dismantling them for repairs.

1,444,584. ELECTRIC FURNACE HAVING RESISTOR DOME; G. H. Clamer, Atlantic City, and J. R. Wyatt, Camden, N. J. App. filed Nov. 20, 1920. Utilizes both reflected and radiated heat from upper furnace walls.

1,444,605. CARRIER-WAVE SIGNALING SYSTEM; R. A. Heising, Millburn, N. J. App. filed Jan. 21, 1919. Method of signaling through successively modulated currents.

1,444,620. AIR-MOTOR-DRIVEN GENERATOR; E. Lunn, Chicago, Ill. App. filed Sept. 12, 1921. Wind-driven generator for charging airplane batteries.

1,444,621. ELECTRIC HEATER; L. F. Lynn and J. D. Lewis, Tacoma, Wash. App. filed Feb. 16, 1922. Air preheated by passing through shell surrounding element before coming into contact with element.

1,444,685. SIGNALING SYSTEM AND RELAY THEREFOR; R. M. Hopkins, Rutherford, N. J. App. filed July 5, 1919. Burglar-alarm system for vaults.

1,444,716. TROLLEY WHEEL; A. C. Van Hooydonk, Monroe, Mich. App. filed May 12, 1922. Two wheels mounted on movable hub.

1,444,742. SIGNAL; F. Guenther, San Mateo, Cal. App. filed Jan. 18, 1921. Alarm to indicate to automobile driver that doors are not properly closed.

(Issued Feb. 13, 1923)

15,538 (reissue). CONTROL DEVICE FOR WIRELESS SIGNALING; E. H. Colpitts, East Orange, N. J. App. for reissue filed Feb. 14, 1918. Current flows in amplifier tubes only during time signal impulses are sent.

15,539 (reissue). TELEGRAPHY; T. B. Dixon; New York, N. Y. App. for reissue filed May 3, 1922. Amplifying telegraphic signals transmitted through cables.

15,540 (reissue). MEANS FOR TRANSFORMING MECHANICAL VIBRATIONS INTO ELECTRICAL VIBRATIONS; L. de Forest, New York, N. Y. App. for reissue filed July 13, 1921. By thermionic tubes.

1,444,777. IMPULSE TRANSMITTER FOR AUTOMATIC TELEPHONE SYSTEMS; J. G. Blessing, Chicago, Ill. App. filed Jan. 26, 1920. Subscriber compelled to remove his finger before dial returns to normal position.

1,444,781. TELEPHONE EXCHANGE SYSTEM; G. Deakin, London, England. App. filed May 26, 1919. Call metering device for automatic telephone system.

1,444,787. ELECTROLYTIC APPARATUS; W. E. Greenwalt, Denver, Col. App. filed June 11, 1920. For the production of hydrogen sulphide and sponge lead.

1,444,804. PUSH-BUTTON SWITCH; F. Sauczuk, Brooklyn, N. Y. App. filed Dec. 8, 1919. For apartment-house announcers.

1,444,805. VOICE-CURRENT TELEPHONE REPEATER; A. B. Smith, Evanston, Ill. App. filed March 5, 1919. Method of switching voice-current amplifier from trunk line to repeat in one direction to connections which adapt it in opposite direction.

1,444,827. CONTROLLING SYSTEM FOR MINE-BLASTING OPERATIONS; S. F. Bridwell and J. F. Kennedy, Terre Haute, Ind. App. filed May 25, 1921. For selectively firing blasts within mine by electricity.

1,444,830. TRANSMISSION CONTROLLING APPARATUS; C. S. Demarest, Brooklyn, N. Y. App. filed Aug. 9, 1919. For controlling operation of four-wire repeater circuits.

1,444,858. SWITCH BOX; G. B. Wadsworth, Covington, Ky. App. filed Oct. 11, 1917. Safety box in which switch must be turned before exposing fuses.

1,444,886. SPEED INDICATOR FOR AËROPLANES; E. W. Rounds, Washington, D. C. App. filed July 30, 1921. Chronograph for recording the ground speed of aëroplane while taking off or landing.

1,444,887. METHOD OF PRODUCING PURE IRON BY ELECTROLYSIS; A. Schwiete, Frankfort-on-Main, Germany. App. filed May 31, 1922. Electric current acts on slightly acidulated solution of ferrous chloride.

1,444,939. ELECTRIC FURNACE; T. A. Reid, Pittsburgh, Pa. App. filed April 25, 1921. Support of resistances in furnaces.

1,444,940. RESISTOR-SUPPORTING MEANS; T. A. Reid, Pittsburgh, Pa. App. filed June 3, 1921. For electric furnace.

1,444,947. CONTROL APPARATUS; A. H. Candee, Pittsburgh, Pa. App. filed Oct. 30, 1918. Emergency braking equipment for electric railway vehicles.

1,444,948. ELECTRIC FURNACE; C. H. Carpenter, Wilkinsburg, Pa. App. filed April 23, 1920. Container for the material acts as resistor.

1,444,958. ELECTRIC HEATER; F. W. De Luchi, Oakland, Cal. App. filed Feb. 13, 1922. Electric room heater.

1,444,961. ARC-LAMP ELECTRODE; H. B. Eynon, Lakewood, Ohio. App. filed June 11, 1919. Negative projector electrode composed of three forms of carbon.

1,444,962. ARC-LAMP ELECTRODE; H. B. Eynon, Lakewood, Ohio. App. filed June 11, 1919. Negative projector electrode consisting of carbon shell, graphite core and intermediate filling of powdered graphite.

1,444,980. ELECTRIC FURNACE; W. E. Moore, Beaver; H. F. Alter and E. A. Hanff, Pittsburgh; J. R. Eckley, New Kensington, Pa., and F. Wright, Newport, Ky. App. filed Sept. 5, 1919. Electric arc furnace of rocking type.

1,444,983. TROLLEY BASE; W. Schaake, Pittsburgh, Pa. App. filed Oct. 9, 1920. Construction of trolley-pole base.

1,445,019. ELECTRIC WATER HEATER; J. Joeschke, Berlin, Germany. App. filed May 5, 1922. Connected directly to water faucet.

1,445,025. STORAGE-BATTERY SYSTEM; S. E. McFarland, Los Angeles, Cal. App. filed Nov. 5, 1919. Any portion of battery can be used while charging.

1,445,072. TERMINAL BOX; W. L. Cook, Chicago, Ill. App. filed Nov. 20, 1919. Telephone board for use with underground cables.

1,445,089. TROLLEY GUARD AND FINDER; P. J. Kelley, Detroit, Mich. App. filed Oct. 23, 1922. Enables quick raising of pole into contact with wire.

1,445,120. MULTIPLE INCANDESCENT ELECTRIC LAMP; N. Wise, New York, N. Y. App. filed Feb. 7, 1919. When one filament is burned out second is used.

1,445,141. SIGNALING SYSTEM; B. W. Kendall, New York, N. Y. App. filed Dec. 18, 1916. Multiplex telephony by means of modulated carrier currents.

1,445,149. FLOOR-LEVEL STOP FOR ELECTRICALLY OPERATED ELEVATORS; E. R. Leigh, Philadelphia, Pa. App. filed Sept. 22, 1917.

1,445,169. DENTAL FILM HOLDER; H. G. Ralph, Edenton, N. C. App. filed Feb. 14, 1921. For holding X-ray films.

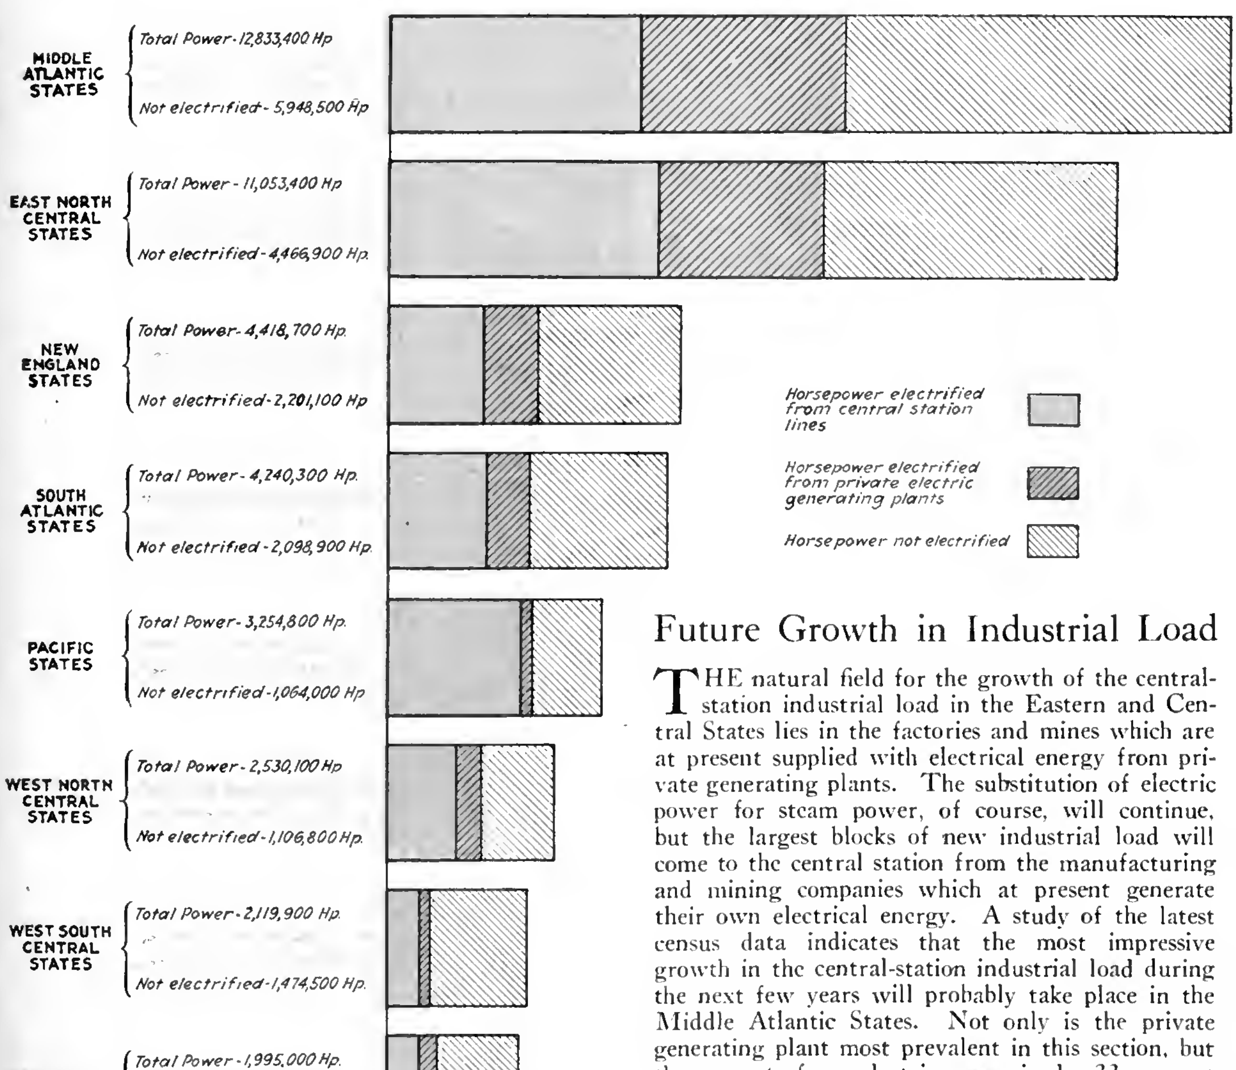
1,445,178. FEEDER CLAMP FOR OVERHEAD-TROLLEY SYSTEMS; P. G. Schwarz, Indianapolis, Ind. App. filed Dec. 22, 1919.

# Business Facts for Electrical Men

Selected Statistics Presented Graphically for the Use of All Interested in Analyzing the Trend of the Electrical Business

## Extent to Which the Mills, Factories and Mines of the Various Sections of the Country Are Electrified

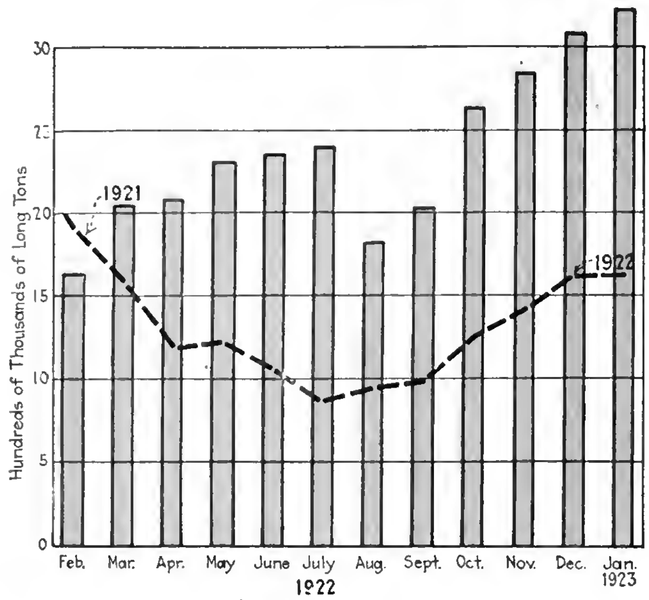
(Data as of Jan. 1, 1920)



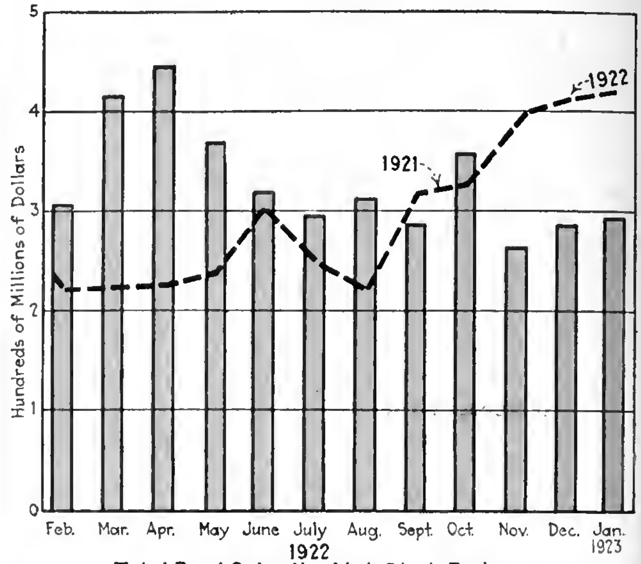
### Future Growth in Industrial Load

THE natural field for the growth of the central-station industrial load in the Eastern and Central States lies in the factories and mines which are at present supplied with electrical energy from private generating plants. The substitution of electric power for steam power, of course, will continue, but the largest blocks of new industrial load will come to the central station from the manufacturing and mining companies which at present generate their own electrical energy. A study of the latest census data indicates that the most impressive growth in the central-station industrial load during the next few years will probably take place in the Middle Atlantic States. Not only is the private generating plant most prevalent in this section, but the amount of non-electric power is also 33 per cent in excess of that existing in any other section of the country. The central stations of the Far West, on the other hand, will be compelled to build up their industrial load either by the conversion of steam drive to electric drive or by the electrification of new mills and mines plus the ever-growing irrigation load.

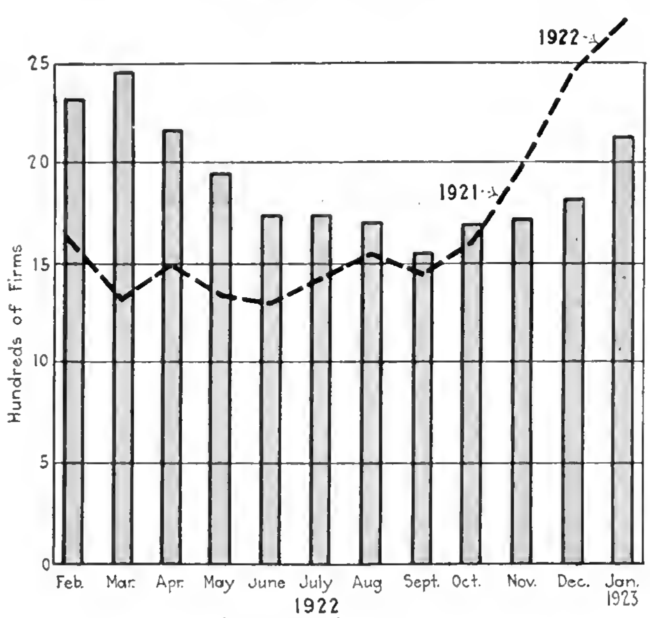
# How the Primary Industries Are Trending



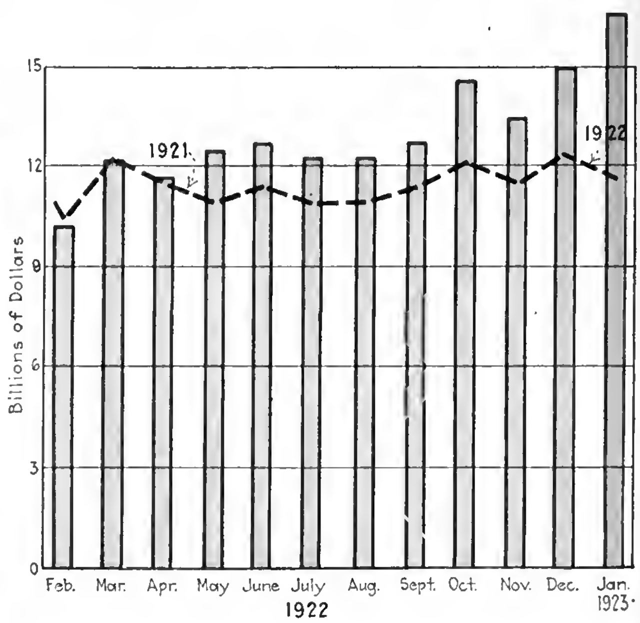
Pig-iron Production



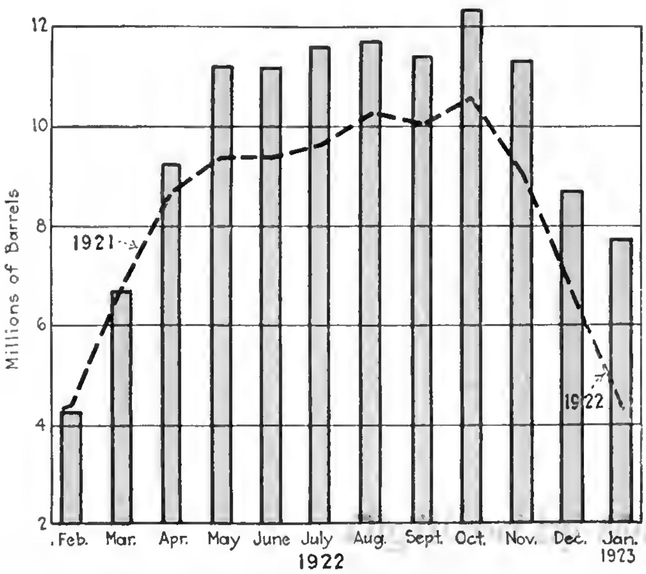
Total Bond Sales, New York Stock Exchange



Business Failures



Bank Clearings
(Outside of New York City)



Portland Cement Production

## Bank Clearings Indicate Prosperous Conditions

ONE of the most significant indices of general prosperity during January was the unusual bank clearings reported for that month. Many prominent economists and statisticians consider bank clearings outside of New York City as the most reliable barometer of the growth of American business. The figure of $16,562,000,000 reported for January represents the largest bank clearings outside of New York City reported since March, 1920, and data available indicate that it is the third largest figure ever reported for any one month. The January clearings increased 42.5 per cent over January, 1922.

Pig-iron production continued to climb during January, being almost double the production reported for January last year. A study of the growth in pig-iron production for many years in the past indicates that the production during January was about 5 per cent higher than the production which would normally be expected for that month.

Electrical World

# The More Vital Credit

EVER since men turned from warfare as a normal occupation and became engrossed in industry and business, credit has been enthroned on high. Security, opportunity and prosperity have been maintained not by the sword, but by the greater resources of peace—service, fair dealing, responsibility, capital. And out of capital and character men have also built credit — which brings the privilege of calling to their needs the capital of others, lodged in the bank as a common fund for the use of industry.

And so the executive of every public utility, of every manufacturing enterprise and of every jobbing, contracting or retail merchandising or other business strives to establish credit at the bank. He realizes that the good will and confidence of the bank are greater assets to him than all his money on deposit. He knows that with the bank behind him he can expand and grow and meet his troubles when they come. But he forgets sometimes that *it is even more important to cultivate credit with the public than with the bank.*

CUSTOMER ownership of securities is a demonstration of the awakening of business men to the significance of this great truth. Public utilities are selling their stock to their consumers that people may become interested in utility problems and concerned with the prosperity of the public service corporations of their communities. Manufacturing companies are assisting their employees to purchase shares that self-interest may develop loyalty and promote thrift among them. Men are suggesting that the tribulations of the railroads could be ended by the sale of their securities to their employees and to the shippers and passengers whom they serve. It is dawning upon our minds that the public has an interest in and an influence upon the affairs of all individuals and all business enterprises.

Public sympathy with its purposes, public approval of its methods, public confidence in its product, public respect for the character of its personnel, public good will toward its activities, public pride in its success — these are great resources for any business. In short, this intangible but very present thing that can best be called *credit with the public* is an asset as valuable as, even more valuable than, credit at the bank.

THERE is a great thought in this that should be pondered well by the executive of every central station and every other electrical business. It should be well taught to all employees. It should be a guiding principle in all their work, clearly expressed in their relations with their customers.

For the entire electrical industry is virtually founded upon our great utility services, publicly regulated and more and more publicly owned. Credit with this public is therefore absolutely vital.

# Thomas Addison

*An inspiring example to all electrical men and an executive who has built up the electrical industry in the West.*

SIX years after the Thomson-Houston Company had in 1884 made a spectacular start on the Pacific Coast by installing an incandescent lighting system at Sacramento Dr. Thomas Addison of Chicago came to take charge of the Western branch of the company. The first electric railway of California was under construction at San José at the time, and the first duty of Dr. Addison—who had entered the new electrical field after eight years of practice as a graduated physician—was to oversee the installation of Thomson-Houston equipment. From that time on his story may be said to be the story of the growth of a great company. Its Western branch passed through the phases of amalgamation with the Edison General Electric Company and its change to its present form under his direction. From being an organization confined mainly to the handling of generating equipment, it expanded into the field of motors and became a factor in the growth of irrigation as a power-company load, making its contribution as well to the rapid industrial development of the Coast.

Dr. Addison, who was born in Courtland, Mich., was graduated from Bellevue Medical College with the class of 1877. In 1885 he forsook his profession to take employment with the United States Electric Company of Chicago, and in 1888 he accepted a position as apparatus salesman with the Thomson-Houston Company at that city. When the Western branch of the company was reorganized in 1890 he was selected to go to San Francisco as local manager. Two years later he became Pacific Coast manager of the General Electric Company, and this post he has filled for more than thirty years.

Dr. Addison's great contribution to electrical progress has not been confined to the advancement of his own company. He has taken an active part in the upbuilding of other branches of the industry besides his own and has shown a warm interest in the formation of local technical and commercial organizations and their development to their present importance. His sympathetic encouragement has been an active factor in the cultivation of such new fields as electric pumping in irrigation or, more recently, the advance of electricity into the oil fields.

For twenty years he acted as chairman of the board of trustees of the State Normal School of San José, and at one time he was a director of the Berkeley National Bank. He is a man of wide interests and a member of many associations and clubs. "The Doctor," as he is affectionately called, is often termed the father of the industry in the West.

Electrical World, March 3, 1923

Volume 81 Number 9

### oad Factor Versus Diversity Factor

N HUNTING for load-factor business the tendency too frequently is to bait the hook with a ridiculously w energy rate. This policy is short-sighted, especially the case of steam-operated systems, because load fac- r is desirable at all times provided it is obtained from stem diversity factor. Diversity factor forms the rnerstone of the electric light and power business. ypical examples of two systems, each fitted for the rticular kind of load it carries and neither of them pable of carrying the load of the other profitably, will iffice to illustrate the point.

The system of the Niagara Falls Power Company is e finest example of hydro-electric development in the untry. That is to say, it has abundant water, needs steam reserves and consequently operates at low cost. he yearly load factor of the system approaches 100 per nt. During 1922 the company generated considerably ore than two billion kilowatt-hours, and its gross in- me was more than six million dollars. It does a ad-factor business. The Commonwealth Edison Com- my, on the other hand, furnishes an excellent example an efficient steam-driven system. Its output, while t quite so large as that of the Niagara Falls Power mpany, nevertheless was more than two billion kilo- att-hours last year. From the sale of this energy income was approximately forty million dollars oss. Of course, it costs more to generate electricity Chicago than it does at Niagara Falls; but that is t the point we wish to make. We merely compare a pical and excellent load-factor system with a typical d excellent diversity-factor system. The Hydro-Elec- ic Power Commission of Ontario furnishes another ample. Although the provincial commission buys wer at, say, $30, the local Hydro systems sell for, say, 0. In the first case twenty-four-hour power is in- lved (load factor), whereas the local community sells ght-hour power two or three times over (diversity ctor).

### ake Your Business Office Conspicuous

WHY is it that many central-station companies make their business offices and display rooms so conspicuous? In some cases it seems as if an actual tempt is made to keep these places hidden. Recently man who had business with a central-station company a city in which there is competition with a municipal ant inquired at a retail electrical merchandising store to the location of the office of the private company d received directions which led him to the municipal- ant office. It was here that the location of the office the private company was ascertained. The first rection might have been a result of misunderstand- g; but inquiries from a traffic policeman and from several persons in small stores using electric light revealed ignorance or brought directions to the municipal office.

After a half hour of wandering, the building, in which there are two utility business offices, was found. Its front was dominated by a flaming electric sign belonging to a totally unrelated business. From across the street it was almost impossible to read the small window signs on each utility office window, and it would have been easy to pass both offices on the same side of the street without seeing them. Both, however, were attractively arranged, and the reception of the inquirer was courteous and all that could be asked.

In noticeable contrast with these inconspicuous quarters numerous signs, electric and otherwise, advertising other businesses could be seen in every direction from the entrance to the building. Despite the fact that the municipal office was in an out-of-the-way place, it had an electric sign that could not be missed, and at another point in a conspicuous location was an enormous electric sign advertising the municipal-plant service.

Except that there is competition in this particular instance, the situation can be duplicated in altogether too many other places. Such central stations seem to be like the physician who will not take his own medicine or the cobbler who cannot provide his own family with shoes. There is something fundamentally wrong with business policies of this sort. The business office of the utility ought to be at least as conspicuous as any business enterprise in town.

### An Electrical Giant Makes Its Bow to Industry

PLATO said that society arises because different men are better skilled to supply different wants and thus the wants of each are supplied by mutual arrangement and division of labor. It might well be said today that industry progresses because electricity becomes more and more applicable to the supply of its needs and permits it to conform more nearly to the statement of Adam Smith that division of labor is the chief cause of improvement in its productiveness.

With untiring persistency, electricity is invading every industry and, through its flexibility, ease of control, safety and adaptability to every need of the industrial process, is eliminating waste, increasing production, bettering working conditions and changing production methods. This unceasing invasion is unprecedented in industrial history and yet is so universal and so gradual that it is difficult to record decisive victories in its progress. What is required is a record of the state of electrification in the different industries at intervals which afford data for making comparisons over a period of time.

In this issue of the ELECTRICAL WORLD a very complete, new all-electric paper mill is described, with detail

tabulations of all the electrical equipment and with statements of the engineering reasons for its selection and installation. The magnitude of the project, with its 65,000 hp. in motors, necessitated the use of a greater number of pages than are usually devoted to one article, but the fascinating story of paper making, in the opinion of the editors, makes the article unusually interesting. The recording of the electrical statistics of this great paper mill should serve a good purpose. The story is typical of the electrification existing or coming into being in many other industries.

In its engineering features the paper mill is most interesting from the control standpoint. The paper machine presents a control problem for engineers whereby precise adjustments of speed over a wide range of speeds are required on a group of direct-current motors operating on the same machine but without mechanical connection. Faced with this problem, the engineers of the several manufacturing companies obtained solutions which have all been applied with success. An incidental outcome lies in the fact that the same type of control has been found applicable in several other industries.

In its other engineering features the paper mill is chiefly of interest because of the magnitude and number of the motors required and because the power factor of the complete installation is so well controlled by the battery of large synchronous motors. This installation should surely pave the way for similar paper mills in localities where hydro-electric power and forests are found and can be put to good use. In many localities similar to Three Rivers water powers are wasting their energy because they are distant from settled communities, and these should be used to serve industries—for example, the paper industry—until settlement and progress provide other loads.

## Codes of Ethics Are Aids to Higher Professional Standards

THE engineer has long prided himself on his professional standards and has jealously built and guarded his reputation for fair dealing on a plane of high integrity, honor and ethics. On the whole, however, he has been unduly reticent in telling his fellowmen about his ideals and aspirations, his qualifications and characteristics. Men in other lines of professional and business life have recently been active in telling the public how good they are—at least, they have been organizing and "cleaning house" and otherwise arranging affairs to show the people that the conduct of their business is above public or private reproach. As a matter of fact, the art of being good had so far progressed that the American Academy of Political and Social Science was able about a year ago to collect "codes of ethics" from every calling on earth—except the ministry!

However, the issuing this week of a reprint of the "Code of Principles of Professional Conduct" adopted by the American Institute of Electrical Engineers in 1912 calls to mind that, although the engineer has been somewhat quiet about this work, he has been effectively at it for over a decade. The civil engineers adopted a code in 1914 and the mechanical engineers in 1922; the mining engineers still say that the Bible is good enough for them! It should be a point of pride with the electrical engineers that their code was the predecessor—and has served as a pattern—of the other engineering codes. The original impetus was President S. S. Wheeler's address on "Engineering Honor" in 1906, after which committees began to formulate the code as it now stands.

Among professional societies in particular these codes of honor have become important factors in upholding high ideals in the constantly broadening relations of the various groups. The simple statement of desirable professional procedure and attitude has been very helpful, particularly to the younger members of the professions. The American Institute of Electrical Engineers, when the subject was raised again last year, gave evidence of its satisfaction by reaffirming its 1912 code, saying that it "had served its purpose effectively during the past ten years," and by directing its code committee to examine into practices of members which may be regarded as prejudicial to the welfare of the Institute. That the committee has done this effectively in two or three instances is sufficient proof of the desirability and appropriateness of the code.

## Automatic Equipment Does Not Replace Human Intelligence

OCCASIONALLY an engineer or operator with experience that seems to back his opinion rises to declare that some type of automatic installation is going completely to displace the human element in a particular field of electric plant operation. Such declarations, for instance, have been heard about the automatic substation. An examination of the facts usually discloses that a successful installation has been made under a certain set of conditions and does almost all that the enthusiastic individual claims for it, incidentally showing the existence of a broad field of application for its use; but this field comes far short of comprehending the entire range of conditions met with in plant operations of the general character under discussion.

An examination of the application of automatic equipment in the industrial field discloses many types that seem almost to do their own thinking, so marvelous are the results. Such equipment, however, is designed to go through a given cycle of operations. If that cycle does not occur, the machine ceases to function and human hands must be ready to take hold and start the operation anew. Automatic equipment of any type in an industrial establishment merely performs mechanical operations and increases the amount of work that one human being can do by freeing him of things that require no intelligence to perform or that can be reduced to a pure mechanical cycle. This principle is true in the application of automatic devices in the substation or generating plant.

In a recent discussion that finally led to the question of automatic operation in the generating room a prominent engineer said that he expected in the future to see many operations now manual carried on automatically. He mentioned the synchronizing of machines as an example of the type of operation that can be reduced to a mechanical cycle. This, in his belief, will eventually eliminate the human factor from performance of a kind where mental aberration or accident to the operator may prove serious and allow the attendant to look after routine operation as well as the abnormal occurrences which require human intelligence to correct. The idea back of this expression of opinion was that the constantly increasing concentration of power in huge plant units is such that the operator must be relieved of every manual operation possible and left to see the

apparatus is functioning properly. There are more operations to be performed than the human brain can be safely burdened with, and mechanical or electrical devices must be used to increase its power of accomplishment by confining its activities to the operations that actually need thinking power. This is the principle from which the design and installation of automatic plant equipment should be viewed. Its application will many times produce a part of the plant which will not require the physical presence of a human workman for long periods of time. In many other cases it will merely supplement human efforts. It will never completely replace human intelligence.

## Advocates of Superpower Systems Have Lesson to Learn from South

IN MOST discussions of proposed superpower systems the greatest obstacle to accomplishment seems to center around the financing of such a system, the contractual relations and the supervision of operating procedure. The delay seems to be due not so much to technical difficulties as to the inability of the companies concerned to agree on arrangements that will be mutually satisfactory. On these phases of the subject the central-station companies in the Southeastern part of the country have taken the lead.

When the growth of industry and demand for power in this section began to exceed the electric service facilities which each individual company could provide separately, the executives got together. Despite the fact that the extreme tips of the system to be interconnected were more than 900 miles apart, there was no talk of 220-kv. transmission lines, and there still seems to be no need of them. Physically, about the only thing that had to be done was to extend and reinforce certain lines strategically situated between systems and provide sufficient transformer and switch capacity to handle exchange energy. Contractually, it was found necessary merely to agree upon a common frequency, a fixed rate for hydro-electric energy, a sliding-scale rate for steam power, the charge for transferring energy over any system to an adjacent one, and the necessity of one load dispatcher having supervision over all the interconnected systems so far as interchange is concerned. Aside from these preliminaries there were practically no other agreements except a gentlemen's understanding that if one company needs energy and another can furnish it there will be an interchange of power.

No supervoltage lines were required because in transferring power from one extreme side of the system to the other the energy is relayed. For example, if the Yadkin River Power Company desires power, the Alabama Power Company may deliver it to the Georgia Railway & Power Company's system, which will utilize it in the portion of its system nearest Alabama. In turn it will deliver energy from that portion of its system nearest the Carolinas to the Southern Power Company, which will relay the energy in the same manner to the ultimate user. To allow for line loss, each company requires that a fixed percentage over the power to be transferred be delivered to it.

In building the lines to interconnect the adjoining systems there was no quibbling over who should pay for them. Each company paid for the portion of the line within its own state or recognized service district, realizing that it would benefit as much by the interconnection as the adjacent system and also that the line might open up new markets for power.

Rates for power are plain kilowatt-hour rates without complications such as power factor, load factor or demand clauses. The wattless load is distributed by the central-system load dispatcher by asking one company or another to raise or lower its voltage.

In other words, every one entering the superpower system recognized that he would benefit by receiving power when sorely needed or by selling surplus power, and that hence some inconveniences or apparent inequitable division of expense would have to be accepted.

The best proof that these arrangements are agreeable to all is that the Southern superpower system has been operating as such for several years and is still in active existence and that no marked changes have been made in the agreements. The companies admit that improvements can be made, such as still further to reinforce some tie lines and tie transformers or circuit breakers to permit greater exchange of energy without unstabilizing synchronous operation, to make additions or changes which will prevent excessive fluctuations in frequency, to improve relay protection, and so forth. However, all these problems are being attacked already. The unanimous conclusion of the companies is that they are more than satisfied with their superpower system and the method of operation.

The experience and practice of this Southern group of companies should serve as an example to other sections of the country and should also make a worth-while study for politicians who are ranting about adequate utilization of water power for the benefit of the people.

## Carrying the Annual Meeting to All the People

THE broadcasting by radio of the proceedings of the annual stockholders' meeting of the Commonwealth Edison Company last Monday was an interesting and significant innovation in utility public relations. About fifteen hundred stockholders attended the second annual meeting at which provision had been made for a large popular attendance. But, since there are now 28,499 shareholders, this left 27,000 persons who for various reasons were not actually present, although no less concerned. There are, besides, the 610,000 customers of the company who are interested in both the welfare and the activity of this public service corporation. Normally, many of both groups would gain some knowledge of the meeting from the report in the morning papers, but in addition, this time, radio was utilized to bring practically into the audience all those who cared to "listen in" to what was being said and done by the gathering in "Customers' Hall."

It was, of course, a gesture, but it means much. The broadcasting of President Samuel Insull's address, of recommendations from the board of directors for the authorization of a twenty-million-dollar increase in capital stock and of the action of the meeting in indorsing this recommendation was the acknowledgment by the utility not alone of the right of shareholders to be informed and to participate but of the interest and concern of the general public also. It was a graceful and deliberate expression by one of the most important central-station companies of its responsibility to all of its stockholders and to all the people.

## Shawinigan Power Makes Paper

HYDRO-ELECTRIC power is applied to do all the work required in the production of 275 tons of "news" paper each day in this 100 per cent electric mill of the St. Maurice Lumber Company at Three Rivers, Canada. Electricity is particularly well fitted for the operations required in paper making and, since water power and forests are usually found associated with each other, the electric paper mill works under the most economical production conditions and develops natural resources.

# A New All-Electric Paper Mill

By A. H. WHITE* and
R. H. ROGERS†

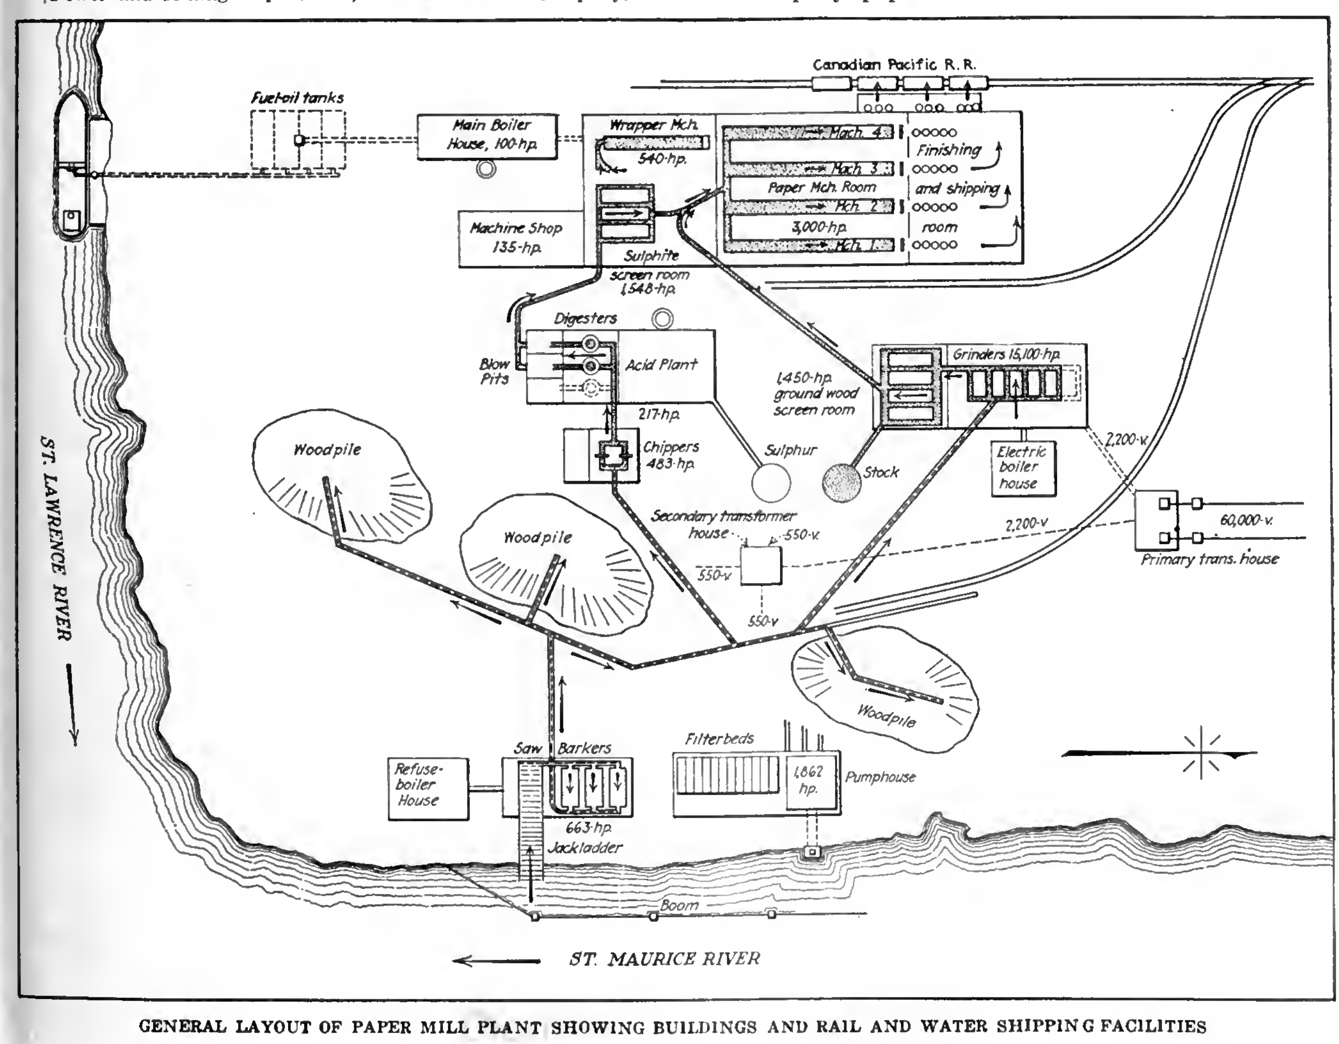
**Process Requirements Governing the Selection of Motor, Control and Electrical Equipment for the Electrification of Paper Mills—Installation Details for 65,000-Hp. Motor Drives and Description of Electrical Material-Handling Equipment Required in the Production of Paper**

SAMUEL DE CHAMPLAIN, as he was exploring from Quebec toward the Great Lakes, discovered a broad river coming into the St. Lawrence from the north, divided at its mouth into three channels by two islands. He founded a settlement here in 1634 and called it Trois Rivières, the Three Rivers of English-speaking people. That it is a strategic point for the production of pulp and paper is proved by the number of successful mills in the vicinity and the rapid, healthy growth of the city since their coming. The St. Maurice River, clear and broad, taps the great forests of the north and furnishes the vehicle that brings the logs to the saws. Its energy, converted at Shawinigan Falls and Grand Mère, not far from its confluence with the St. Lawrence, furnishes 275,000 kw. of hydro-electric power to neighboring industries. The clearness of its water materially aids in the production of a "bright sheet," and steam boilers fed from the St. Maurice show the sustained efficiency that can come only from an ideal feed water.

The transportation facilities here, midway between Montreal and Quebec, are excellent. The St. Lawrence furnishes a water route for incoming pulp wood and for finished paper to Great Lakes ports, Atlantic Coast and European cities during seven months of the year. Fuel-oil tankers steam up from the sea to dock and discharge to mill storage tanks. The canal route via Lake Champlain furnishes a much-used outlet directly to New York City. The Canadian Pacific Railroad with ample sidings keeps the local industries in touch with the whole continent.

In such a setting is the newest mill of the International Paper Company, known as the St. Maurice Lumber Company paper mill. It is the business of this

*Chief engineer the International Paper Company.
†Power and Mining Department, General Electric Company.



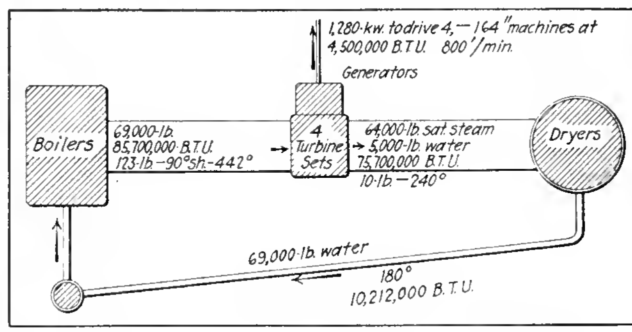
GENERAL LAYOUT OF PAPER MILL PLANT SHOWING BUILDINGS AND RAIL AND WATER SHIPPING FACILITIES

plant to produce news paper composed of about 75 per cent mechanical (ground-wood) pulp and 25 per cent chemical (sulphite) pulp, made from logs that average about 60 per cent spruce and 40 per cent balsam.

The four 164-in. paper machines, to which the whole organization and structure are subservient, were put in production in the past summer—the last one in August. They are already making over 275 tons of "news" per day, and their ultimate capacity, after the installation of the seventh grinder unit and the third digester, will be more than 300 tons per day. The present daily production represents more than 1,200 acres of paper, or a sheet 12½ ft. wide and 875 miles long, turned out at the rate of over 36 miles per hour.

One ton of "news" as now being produced at this mill (based on one month's figures) requires a little over a cord of wood, 1,347 kw.-hr. of hydro-electric power, 7.21 tons of steam produced by 3⅛ barrels of fuel oil for mill heating, pulp cooking, paper drying and for direct-current electric power for driving the paper machines; fifteen man-hours of labor and supervision, and five and a quarter minutes for production.

The logs, 13 ft. to 16 ft. in length, are sawed and barked during the summer months, and the surplus

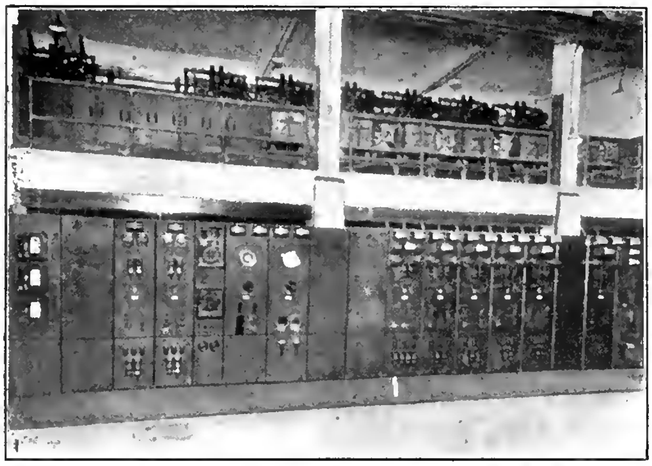


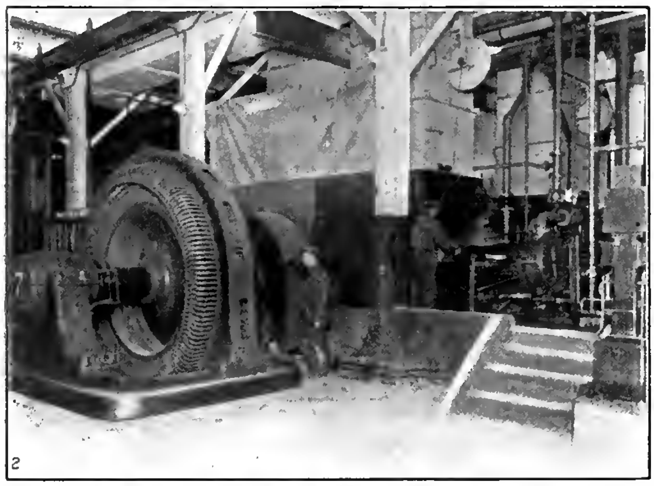
HOW THE HEAT IS DISTRIBUTED IN THE STEAM CYCLE USED IN THE MILL

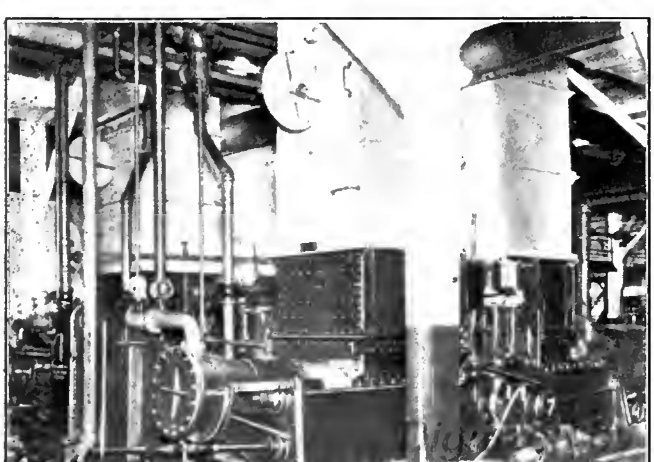
over current demand up to 66,000 cords can be stored for winter. The four fuel-oil tanks hold 150,000 barrels, or more than six months' supply of Mexican residue. Two transmission lines and transformer banks can furnish 24,000 kw. of hydro-electric power. The pump and filter plant has a capacity of 20,000,000 gal. of filtered water per day. The main boiler house can turn out more than 6,000 boiler-horsepower continuously.

The outstanding feature of this mill is the extent to which electric power is used, together with the novelty of many of its specific applications. Every application of power is electric, and it is the only 100 per cent electric paper mill in the industry.

Two 60,000-volt, 60-cycle, three-phase transmission lines come from the north to the main transformer house at the northern limits of the mill yard. Six single-pole, 600-amp., 110,000-volt disconnecting switches lead to the two three-phase, four-tank, 60,500/72,500-volt lightning arresters, which are of the electrolytic outdoor type. Six 600-amp. cylindrical suspension







**Synchronous Motors Grind the Wood**

No. 1. Main switchboard in ground wood mill controls six synchronous motors aggregating 14,400 hp.
No. 2. Hydraulic rams force the logs against the synchronous motor-driven grinder. At right is automatic motor load regulator which is actuated by hydraulic pressure.
No. 3. Six of the seven 2,200-volt, 2,400-hp. synchronous motors which drive pulp grinders.
No. 4. Every three hours a stone-burring lathe is automatically brought into operation without stopping production. The toothed wheel in the magazine feeding pulp grinders registers the cords of wood fed to machine.

outdoor choke coils are interposed just outside the 100,000-volt wall bushings. After going through two 600-amp., 66,000-volt, triple-pole, single-throw, remote-control oil circuit breakers the voltage is stepped down from 66,000 to 2,300 by means of six 4,000-kw. oil-insulated and water-cooled transformers.

Well protected in a room at the end of the transformer house is the four-panel instrument board, where the incoming power is metered on the 2,300-volt side of the transformers. The instruments installed are watt-hour meters, indicating and curve-drawing wattmeters, indicating voltmeters and ammeters, ground detectors for the cable system and an indicating power-factor meter. On these panels are also mounted all necessary instrument protective devices. The entire equipment of this main transformer house was furnished by the Canadian Westinghouse Company with the exception of the transformers, which were built by the Westinghouse Electric & Manufacturing Company.

A tunnel 150 ft. long takes 2,300-volt power from the main transformer house to the switch house alongside the wood grinder room, where there is a connected load of 15,100 hp., with another 2,400-hp. unit on order. The conductors through the tunnel are eight three-conductor, 1,000,000-circ.mil, 2,300-volt cables.

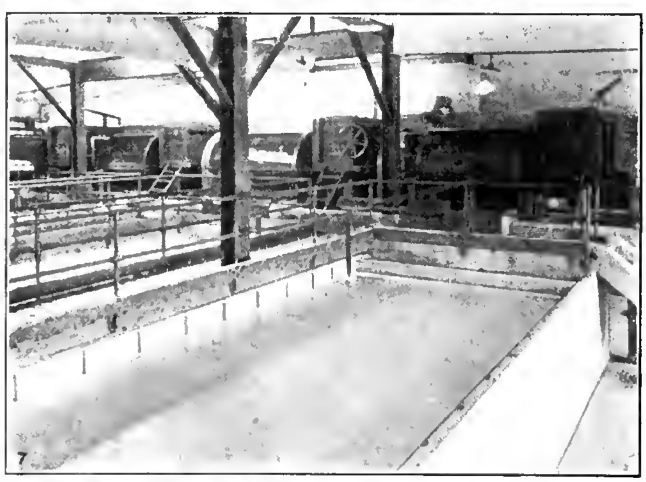
### Secondary Transformer House for Mill Supply

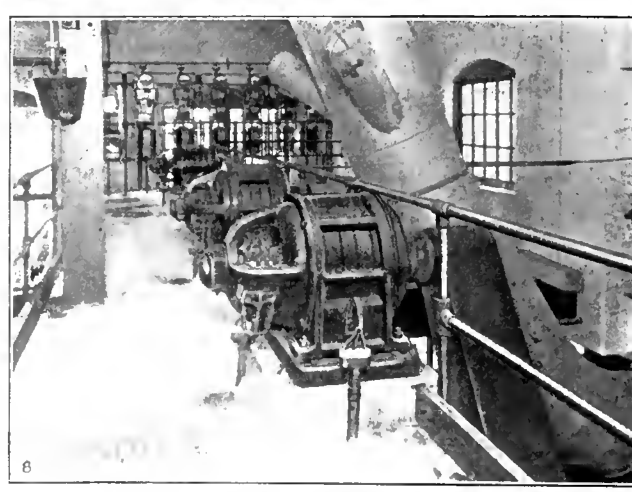
There is a secondary transformer house located conveniently for general distribution to the mill and connected to the main transformer house, 960 ft. away, by two sets of twelve 4-in. ducts with manholes about 150 ft. apart. Twelve ducts each contain a three-conductor, 600,000-circ.mil, 2,300-volt cable; five ducts each contain a three-conductor, 300,000-circ.mil, 600-volt cable, and another contains a two-conductor, No. 2/0 cable for 125-volt direct-current switch control.

The secondary transformer house steps the 2,300-volt circuit down to 550 volts for general distribution throughout the mill and yards. There are mounted here twenty-four 1,200-amp., single-pole, single-throw, 2,200-volt disconnecting switches, twelve 4,000-amp. similar switches and two 2,000-amp. automatic solenoid-operated oil circuit breakers. The transformers are four in number, rated at 2,000 kw. and 2,200/600 volts, and are single phase, oil-insulated and water-cooled. The fourth transformer can be phased in with any other two. There is a 10-kw., 550-110/220-volt lighting transformer installed here, as well as a battery-charging set and a storage battery for switch operation.

Protection is provided by twenty-eight 600, 400 and 300 amp., triple-pole, single-throw, oil circuit breakers, very neatly and conveniently connected and mounted. Eighteen switchboard panels carry curve drawing and indicating instruments for metering the power to various mill divisions.

Four principal lines of ducts radiate from this secondary transformer house and branch off as required to serve the widespread areas of motor applications. The aggregate length of 4-in. ducts, including spares,

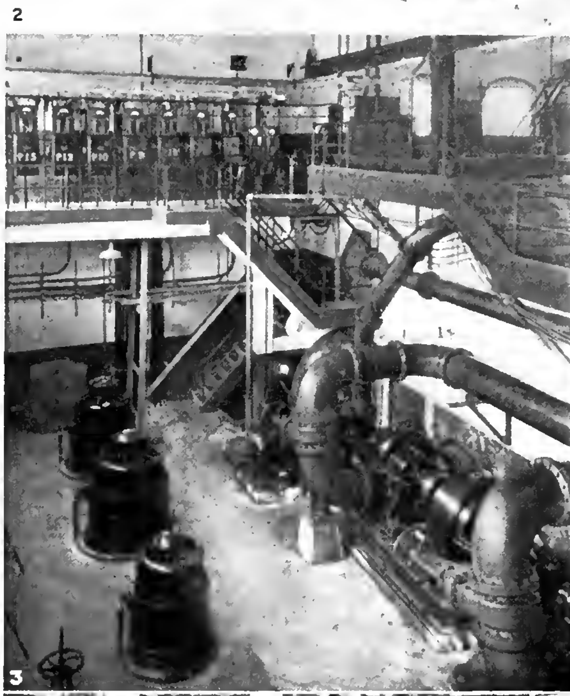




**Grinding Wood and Cleaning Pulp**

No. 5. One of two 220-ft. conveyors above charging floor in ground wood mill for distributing logs to service piles.
No. 6. From the 200 service piles the logs are placed in the magazine grinders from the charging floor in the ground wood mill.
No. 7. In the screen room there are four Sherbrooke revolving screen knotters in the rear of four rifflers each having eleven submerged dams for extracting sand.
No. 8. Six motors of 15 hp. each drive the deckers. Controllers, meters and switches are in the background.

# Conveying Equipment for Logs and Water Pumping Station



No. 1. There are over 3,000 ft. of outside conveyors of the cable type. This conveyor comes from the wood preparing plant. In the distance is a stacker.

No. 2. This "Jack Ladder" conveyor handles 16,000 logs per day from the river to the saws.

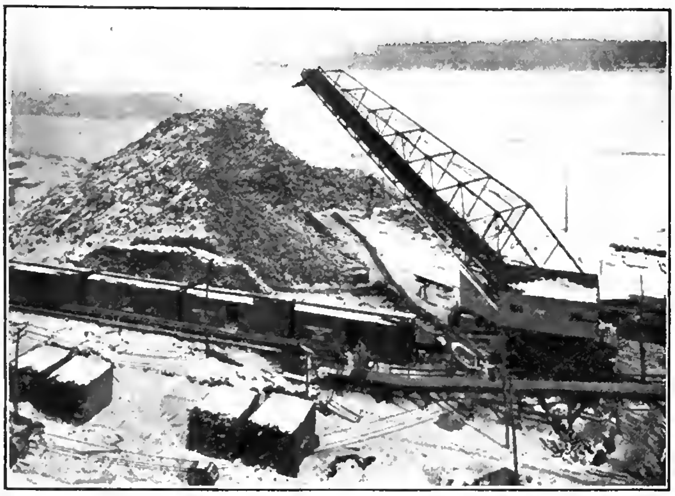
No. 3. In a pump pit below the river level motor-driven pumps furnish water for the filter plant and mill. The control equipment is located above high water.

No. 4. A portable conveyor driven by a 15-hp. motor reclaims logs from storage and takes them to the permanent conveyor for delivery to chipper and grinder buildings.

No. 5. Group of five deckers chain driven from a line shaft. Six of these groups of pulp thickeners are in the ground wood screen room.

No. 6. One of two pairs of high and low pressure pumps for the grinder hydraulic jacks. Compensators are shown at right.

CHIP SCREENS GRADE THE CHIPS AND RETURN OVERSIZE CHIPS TO THE CHIPPERS



LOGS RECEIVED BY RAIL ARE HANDLED BY A STACKER AND CONVEYOR SYSTEM

installed is 15 miles, with access through about thirty-five manholes.

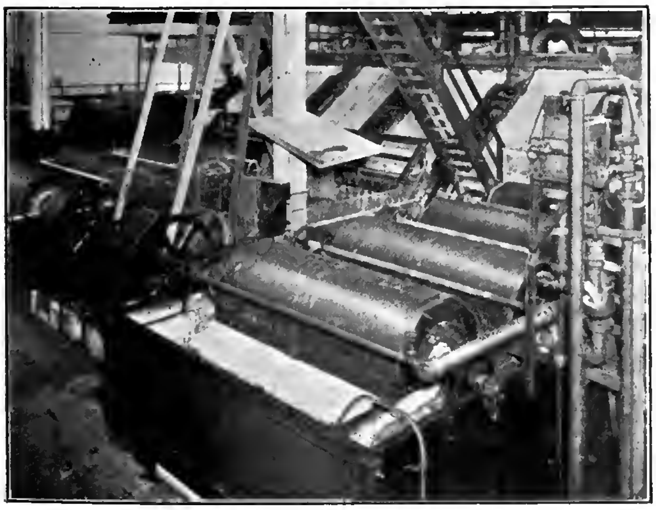
The connected three-phase, sixty-cycle induction motor load totals 34,000 hp. in about 400 motors, practically all controlled by oil switches and compensators or drum controllers so installed that the motor and its connected load is in sight from the control point. An important detail here is that all fuses are eliminated.

Three electric-steam generators are being erected in a separate boiler house close to the 2,300-volt grinder-room switch house. These boilers will have a combined capacity of 1,200 boiler-horsepower and can take 12,000 kw. They will have two functions. They will make available to the mill in the form of steam, at no extra cost other than overhead, the "below-peak" energy that would otherwise be paid for and not used. This procedure, of course, reduces the fuel consumption at the main boiler house to that extent. On Sundays, or at any other time of light steam demand, the 1,200 boiler-horsepower of the electric-steam generators will make it possible to shut down all the oil-fired boilers.

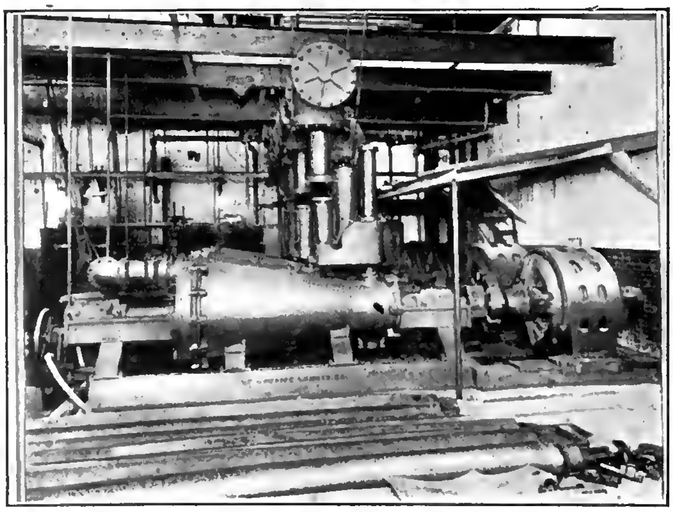
A log boom anchored to piers off shore harbors the logs floated down from the logging camps, and from this inclosure they are hauled sidewise in close formation on a multiple chain conveyor or "jack ladder" to the saws, which can be elevated out of the way of ice during the winter. At the head of the jack ladder they are transferred to another multiple-chain conveyor, which is equipped with jaws that hold securely the individual logs and carry them past the three "slasher" saws that cut them into 4-ft. lengths.

As the 4-ft. logs, end to end, leave the saws, they fall onto a conveyor which takes them endwise to the barking drums, of which there are three. These are huge tumbling barrels having straight-channel iron staves with 2-in. openings between. The drums are mounted horizontally. Both ends are open, and the logs are continually fed into one end and are continually falling over the stationary dam across the other end. The drum is rotated, and at the same time a spray of water is played on the logs. The bark is rubbed, beaten and washed from about 90 per cent of the logs in this process, and those imperfectly barked are returned by a conveyor to the same drums.

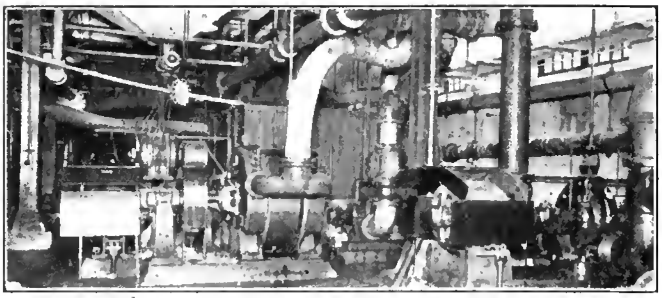
A maximum of 16,000 logs, together measuring more than 50 miles in length, has been drawn from the river, sawed, barked and delivered to the yard conveyors in a day by this wood-preparing plant. The barked logs are then taken in charge by the yard system of cable conveyors, which convey them to the three piles,



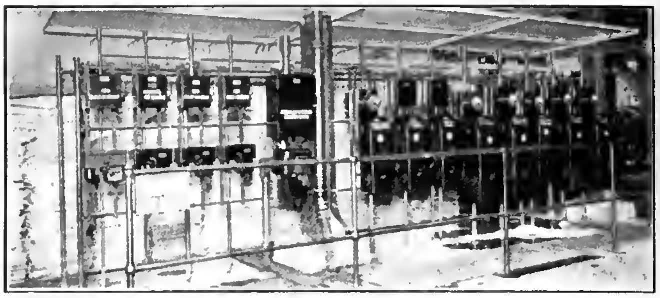
IN THE SULPHITE SCREEN ROOM ARE FIVE INCLINED SCREEN PULP THICKENERS AND TWO WASHERS



AS A RESERVE IN THE SULPHITE SCREEN ROOM ARE FOUR MOTOR-DRIVEN JONES-JORDAN ENGINES



MOTOR-DRIVEN VACUUM AND CENTRIFUGAL PUMPS ARE REQUIRED



COMPENSATORS AND SWITCHES FOR CONTROLLING PAPER MACHINE AUXILIARIES

stack, reclaim and deliver them to the sulphite and ground-wood departments. These cables aggregate 3,000 ft. in length in ten outdoor units.

The motor controllers and protective devices are concentrated in a special control house from which all the conveyor drives can be seen. The control units and instruments are thus protected from vibrations and shocks that they would be subject to if mounted on the conveyor structure.

The barking drums listed in Table I and all the yard conveyor motors in Table II are, it will be noted, of the wound-rotor type on account of the very heavy starting duty with which they are at times confronted. This is especially true of the yard conveyors, which may have to start with a full load of logs or when impeded with snow and ice. Drum controllers are used in the secondary windings with overload oil switches in the primary windings, thus avoiding the use of fuses.

### Pump and Filter Plant for Water Supply

For supplying the enormous amount of water necessary for paper production a pump and filter plant is installed at the river bank. The pump pit contains ten pumps with a combined capacity of 55,800 gal. per minute, or enough to supply a city of 700,000 population. The raw water and fire pumps are below the low-water level of the river. The protective devices, meters and control elements are installed on a gallery overlooking the pit, and they are thus above any danger of flooding. Power is supplied from the secondary transformer house, about 150 ft. away, through three three-conductor, 300,000-circ.mil, 600-volt cables and two three-conductor, 200,000-circ.mil cables. The twenty sand-filter beds occupy an extension, 40 ft. x 180 ft., and they can filter 20,000,000 gal. of river water a day.

The service rendered by this pumping plant is vital, and the pump-pit environment is so exacting from the electrical standpoint that this equipment received the most critical attention in its selection and installation.

The two electric fire pumps are supplemented by a steam fire pump designed for 1,500 g.p.m. against a head of 280 ft. Wherever it is possible the pumps are so designed and connected that they can pump to the fire mains. Cross-connection with the city provides for mutual protection. The whole rotating weight in the vertical pumps is carried on suspension bearings at

MOTOR-GENERATOR SET AND CONTROL UNITS FOR REWINDER MOTOR ON A PAPER MACHINE

the tops of the motors. These bearings have never required adjustment.

The main boiler house lies along the railroad siding between the machine room and the fuel tanks near the southern extremity of the yard. A battery of eight 500-hp. B. & W. water-tube oil-fired boilers extend in a single row down the center with a clear clean space all around them. An inclosure at the north end contains the active electric and the stand-by steam boiler-feed pumps, the fuel-oil pumps and the steam-turbine-driven 180-kw., 550-volt alternating-current emergency generator which is used for lights and machine shops should the hydro-electric power be interrupted.

About 30,000 gal. of fuel oil is being used per day to generate about 5,800 boiler-horsepower from seven boilers at 1.66 load factor. The normal boiler pressure is 125 lb., 95 deg. F. superheat, and the evaporation rate is 14 lb. actual, 15½ lb. equivalent. The draft is 0.1 in. of water, $CO_2$ content of flue gases 13 per cent, and temperature of the flue gases 550 deg. F. The output of two boilers is required for heating the mill in winter. The feed water is admitted at 205 deg. F. from the dryers without heating and is made up from soft filtered river water.

As before stated, the mill product — "news" — is composed of approximately 25 per cent chemical pulp and 75 per cent mechanical pulp; hence the logs leave the storage pile by two routes to meet finally in the mixing system. The sulphite process produces about 1,200 lb. of air-dry sulphite fiber per cord of wood. It may be noted that being floated down the river, tumbled through the barkers and then onto and out of the storage piles so thoroughly mixes the spruce and balsam logs that there is practically no variation in the quality of product, actual checks at the conveyors over several hours having shown that the proportions vary less than 2 per cent.

In the sulphite process the cleanest logs are selected at transfer points in the conveyor system and sent to the chipper building. Here they may be washed in a drum similar to the drum barkers but shorter; then, if knots or discolored spots remain, such logs receive special treatment on a knife barker.

The thoroughly cleaned logs now go to the chippers,

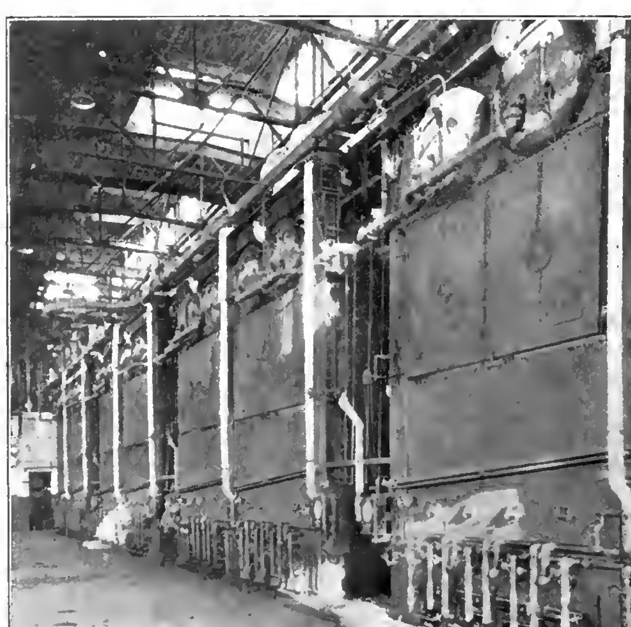
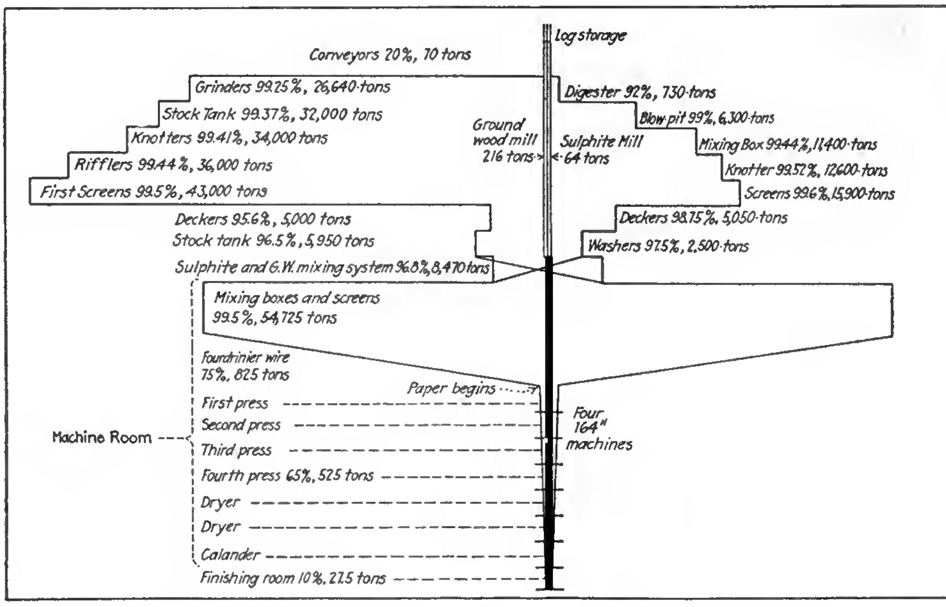
RESISTORS AND CONDUITS UNDER MACHINE ROOM FLOOR. DRYER JACKETS AT RIGHT AND LEFT



IN THE MAIN BOILER HOUSE ARE EIGHT 500-BOILER-HORSEPOWER OIL-FIRED BOILERS

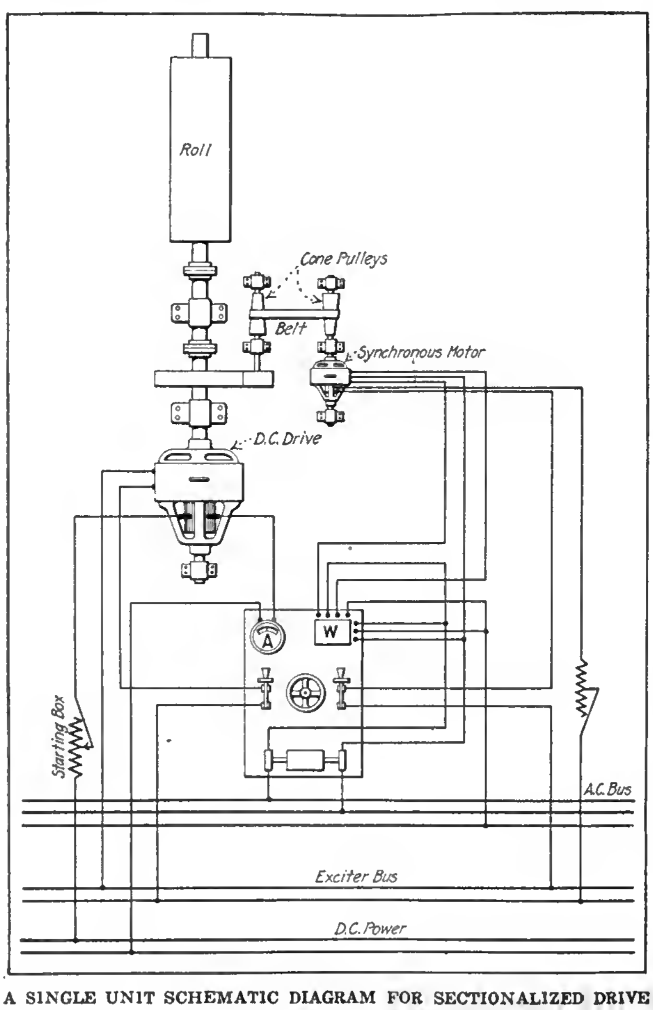


SCHEMATIC OUTLINE OF THE PRODUCTION PROCESS FROM LOGS TO PAPER

of which there are two, each taking its quota. The chipper is a heavy 7-ft. disk carrying three radial blades set as in a plane. The logs by ones, twos or threes, according to size, are fed down a chute at an angle of 45 deg. with the disk, and they are rapidly reduced to chips the size of "small change."

Conveyors take these chips to the tops of large inclined oscillating screens which allow the suitable sizes to fall through onto a conveyor, while the larger pieces slide over a low dam down a chute to the rechipper or "hog" for resizing, whence they return to the screens. Fine particles of the nature of sawdust are blown out and go to the refuse-burning boiler house. The acceptable chips cross over to the digester house on a belt conveyor.

The washing drum and chippers in Table IV are of the wound-rotor type on account of the heavy starting duty. The drum may have to start up with a heavy load of logs in place, and the chippers are characterized by their flywheel effect, which imposes a heavy starting duty.



A SINGLE UNIT SCHEMATIC DIAGRAM FOR SECTIONALIZED DRIVE ON PAPER MACHINE

The chip bin is a huge steel-supported wooden trough just above the digester-charging floor with slide-controlled openings directly over the digesters. By swinging large funnels around on hand cranes, the chips can be discharged into the two digesters, each taking about twenty cords in twenty-five minutes for a feeding.

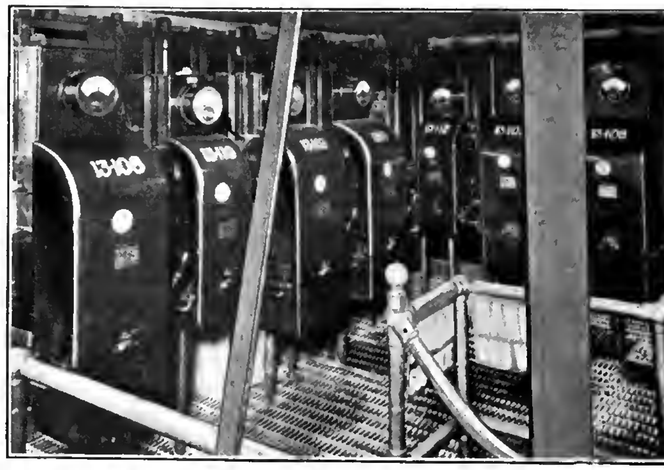
The "acid" building alongside is arranged for preparing and storing quantities of bisulphite of lime. This is made by first melting and then burning sulphur in rotary furnaces and combustion chambers. The resulting sulphur-dioxide gas is water-cooled and forced upward through high towers that are packed with limestone. A supply of water trickles down through the limestone and combines with the gas to form the bisulphite of lime, which is recirculated through the towers before being stored in huge vats.

The digesters are vertical steel tanks with conical top sand bottoms and lined with acid-resisting bricks and mortar. After being filled with chips about 25,000 gal. of bisulphite of lime is pumped in, taking twenty minutes.

Steam is admitted at the bottom, and the pressure gradually mounts to 70 lb., with a resulting temperature of 316 deg. F. The steam flow practically stops after two hours, but the "cook" is continued for over five hours, taking about 250 boiler-horsepower-hours per ton of air-dry pulp. The process of selective digestion lasts about eight hours and is for the specific purpose of digesting the ligneous and resinous binders without harming the cellulose ($C_9H_{10}O_5$) fibers that go into the paper. At the end of the "cook" the contents of the digester are blown into a covered concrete "blow pit," which has a perforated bottom through which the waste liquor drains off to the sewer. The steam and gas fumes pass off through high baffled towers called vomit stacks, which are designed to prevent the escape of pulp. The pulp is now thoroughly washed in the blow pits for several hours until practically nothing remains but the silky unbroken fibers of cellulose.

When the stock leaves the digesters it is 92 per cent water, and it becomes 99 per cent water while being washed in the blow pits. It now goes to a 35,000-gal. stock tank, which stores up enough to convert the intermittent discharges from the digesters into a continuous

EIGHTEEN FLOW METERS ARE ELECTRICALLY RELAYED FROM EIGHTEEN DEPARTMENTS USING STEAM



COMPENSATORS ON GALLERY OVER GROUND-WOOD PUMP PIT TO CONTROL SEVEN PUMPS

process beyond the tank. Horizontal-shaft agitators in this tank keep the contents from settling.

From the tank a steady flow goes through a mixing box, which by the addition of white water from an extracting process further along doubles the volume. A rotary screen of the type called a knotter extracts the coarser clots and fiber bundles, and a still further refinement takes place in the improved rotary meshed-drum "first" screens, which pass only the individual fibers through very narrow slits. The rejected material from the knotters and first screens passes through a "second" screen, which returns the valuable portion to the main stream back of the first screens and sends the coarser parts to the wrapping-paper department.

The stock now cascades down five steep meshed thickeners into tanks in which revolve partly submerged screen thickener drums. The excess water falls through the inclined screens or passes to the inside of the drums, while the pulp adhering to the outside of the drums falls over dams and flows to the soft-stock tank below. The thickeners reduce the water flow from 2,900 g.p.m. to about 400 g.p.m., which leaves the stock about the consistency of thin porridge. The extracted white water goes to a tank, to be worked back into the system in various ways. The screens and thickeners are in a belted group drive with other miscellaneous machinery.

A sulphite soft-stock tank, with a capacity of 45,000 gal., is equipped with a horizontal-shaft agitator to prevent separation. A small addition to this stock comes from two inclined "save-alls" which give the white-water tank overflow a last screening before it goes to the sewer.

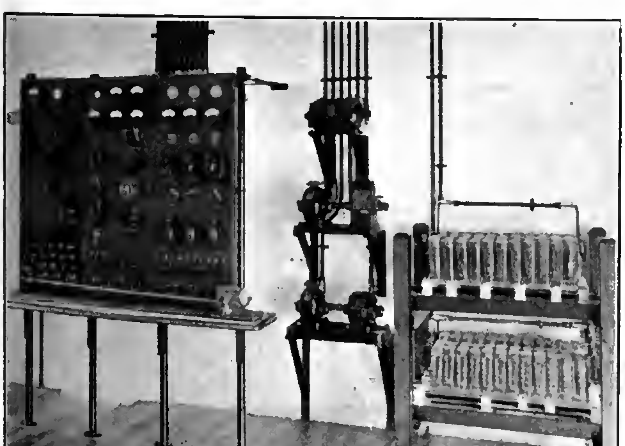
The extreme simplicity of "squirrel-cage" motors make them ideal where the starting duty is comparatively light and where no speed variation is required. They are started with compensators, and in many cases a meter is added to indicate the load. All the motors are protected without the use of fuses.

### THE MAKING OF GROUND-WOOD PULP

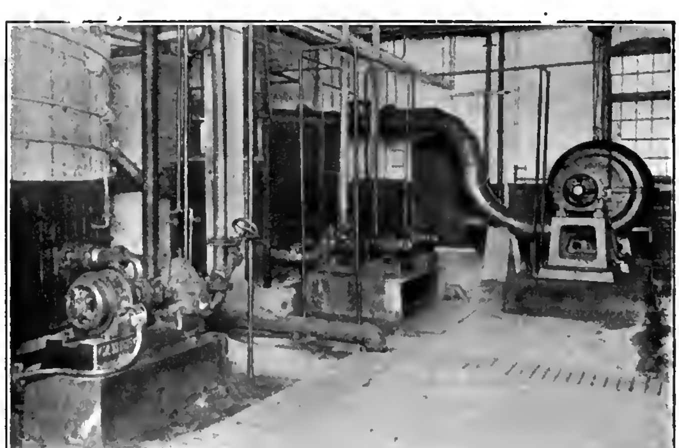
Interest in the ground-wood department centers about the grinders, for here is the heaviest draft on electric power and the greatest material transformation, all carried on with relentless energy and yet with just that skill and delicacy that produce unvaryingly the balance between quality and quantity which goes so far to uphold the mill's production record.

Six General Electric 2,400-hp., 2,200-volt synchronous motors, backed by their switchboards, oil-switch cells, starting compensators and exciter motor-generator sets, form the most imposing array of power in the mill.

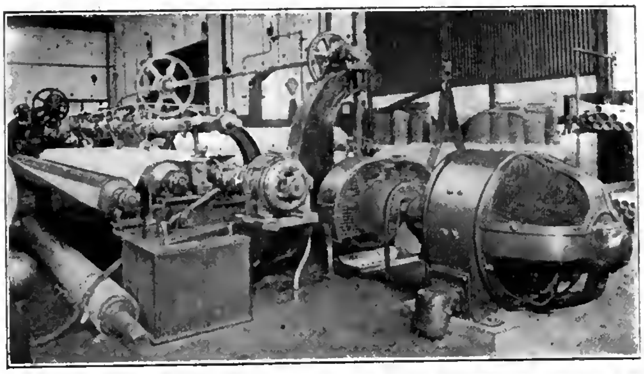
These synchronous motors are designed to allow for a large leading power factor even at fractional loads. As their load far outweighs all the induction motors combined, the power factor for the mill is exceptionally high and is under control through field regulation of the synchronous motors.

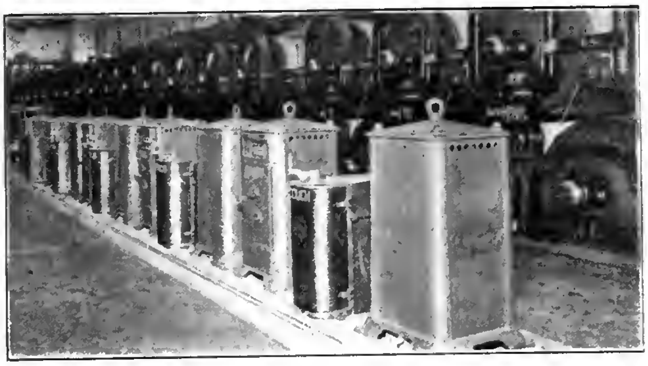


A 25-VOLT STORAGE BATTERY SYSTEM ENERGIZES ABOUT 4,800 CIRCUITS FOR TELEPHONES, FIRE ALARMS, WATCHMEN'S STATIONS, ETC.



AUXILIARIES IN THE SULPHITE ROOM MUST HAVE LEAD FITTINGS AND ACID-PROOF CONSTRUCTION TO PREVENT THEIR DETERIORATION





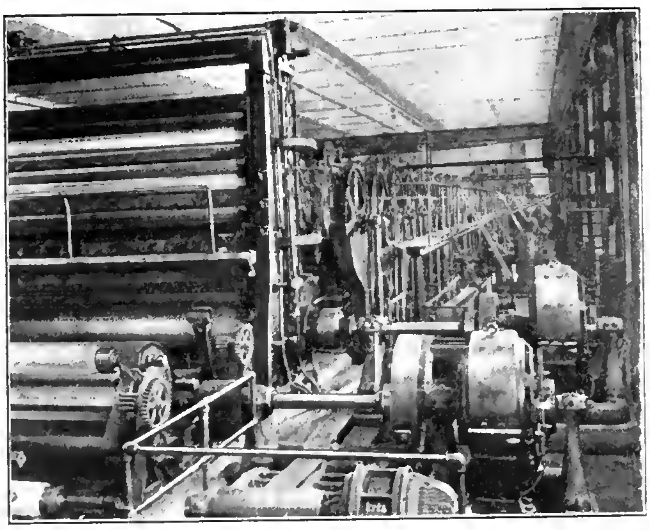
**Many Motors Operate the Paper Machine**

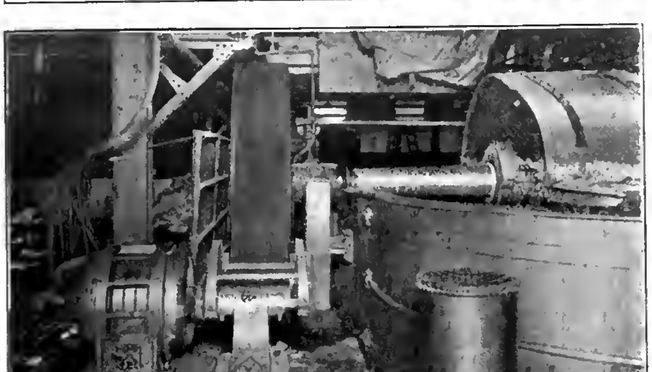
Upper view: An alternating-current motor drives the slitter and a direct-current motor with speed control is used on the rewinder.

Second view: Drum controllers and panel housings for wet end of a paper machine.

Third view: Each of the nine sections of the paper machine has its own motor drive.

Lower view: Motor-driven broke beater for two paper machines using Lenix belt drive.





Wood grinding furnishes an ideal load for synchronous motors as the grinders have light starting load when the pressure is relieved. They have a constant load characteristic regulated by an automatic device, and the total load is so great that the power factor for the whole plant is kept at unity. It is of interest to note that the induction motor load alone has a power factor of 72 per cent.

These synchronous motors are started by reduced voltage-tap compensators, and the power factor is controlled on the individual motors by their field rheostats. The motors are designed for 72 per cent leading power factor and 96.2 per cent efficiency at full load.

Each 2,400-hp. motor is direct-connected to the end of a shaft that carries two grindstones 60 in. in diameter by 54-in. face, thus making twelve stones in all. The seventh set, which will make fourteen stones, is being installed.

The grinders are of the Watrous magazine type—i.e., the wood is fed into vertical chambers that reach to the charging floor, where they are kept filled from wood bins that are in turn kept replenished by the conveyor system. The 4-ft. logs are laid in the magazine parallel to the shaft, making two compact stacks per stone in the magazines with the stone between them at the bottom. The logs that lie alongside the stone on either side are forced against the stone by hydraulic pistons until they are ground away. When the pistons have completed their strokes, they automatically withdraw, allowing more logs to fall into the vacant spaces, when the relentless forward travel of the pistons begins again. The withdrawal of the pistons is accomplished by the low-pressure 50-lb. water system, while the grinding pressure is applied by the 190-lb. water pressure, using, however, only about 150 lb. in service.

Without water the wood would burn and the stones would burst from heat; therefore some 6,000 gal. of white water is flushed over the twelve stones, serving to bring the ground wood away as pulp which is over 99 per cent water. Even so, the heat generated evolves a great amount of steam. This, however, is ejected by an ingenious system which leaves the department unusually clear. In the side of each magazine is a toothed wheel which is turned as the wood sinks toward the stone, and registers the cords of wood ground.

Provision is made for burring the stones at regular intervals by means of a built-in hydraulic burring lathe, without interfering with production, and a light burring at three-hour intervals is said to give very uniform results. Each stone, consuming about 900 hp., grinds 17 tons of air-dry pulp per twenty-four-hour day, and the pulp is of such high quality that refining processes usually resorted to are omitted in this mill.

The pulp after leaving the grinders passes through

inclined sliver screens having a large area, leaving the slivers on the surface, from which they are raked by chain-operated scrapers.

A tank holding 96,000 gal. receives the raw stock, together with the return of useful stock from the second screens further down the line. Still more white water is added in the knotter mixing box before the stock goes to the four improved Sherbrooke rotary-screen knotters. Fiber bundles and other overlarge units are washed off the upper inside surface of the drums and pass to the wrapper-machine system, as was the case in the sulphite department.

The stock now flows into long rifflers, which are fitted with submerged baffles to arrest sand from the stones and other heavy impurities. Four improved rotary first screens further refine the stock while they discharge undesirable matter to the second screens for a rescreening.

A battery of thirty deckers thickens the stock by removing all but about one-tenth of the water. This is done by rotating meshed drums partly submerged in the stock. The water runs into the drum and away to the ground-wood white-water tank, while the pulp left on the surface is scraped off and passes to the concrete cavelike ground-wood soft-stock tank, which holds 890,000 gal. A reserve tank can take 750,000 gal.

### Waste Water Leaves Mill Practically Clear

The white water extracted from the pulp in both divisions and the overflow from the circulating system in the paper mill proper go to their respective white-water tanks. The sulphite tank gets a great quantity from the paper-mill tank, and the ground-wood white water is augmented by a small quantity from the same source. This water all contains valuable pulp, and both divisions make use of "save-alls" to recover a major portion of it. The ground-wood "save-alls" discharge pulp to a "save-all" stock tank, thence to the main soft-stock tank. The water with reduced pulp content passes to the "save-all" white-water tank, thence back into the system by way of the grinders, the sliver screens and the first screens.

In the sulphite department the "save-alls" discharge the recovered pulp directly to the main soft-stock tank. The reduced white water goes in a small part to the mixing box, to the first and second screens, while the major part goes to the sewer at the rate of about 20,000 tons per day. This is practically the only outlet of any size from the system, and by this time the water is practically free from pulp.

### The Two Kinds of Pulp Are Now Mixed

The pulp from both soft-stock tanks as it starts on its way to the mixing system has its consistency regulated by an automatic system which continually samples the flow and admits white water in such quantities as are

needed to keep the flow at a uniform consistency of 96.5 per cent water for the sulphite and the same for the ground-wood stock.

The two streams meet in the mixing system, wherein uniform heads are held against adjustable orifices. The heads are automatically held so that the two streams add 25 per cent and 75 per cent, or whatever other proportion is desired, to the whole. Incorporated with this unit are the feeds for the solution of alum and for the blue color. Both the Trimbly and Allen consistency regulators and the mixing system mentioned above are highly ingenious machines controlled by continuous-running fractional-horsepower motors whose importance in the general process is much greater than their sizes would indicate.

### Another Screening Process Follows

The two machine chests that next receive the "stuff" hold 225,000 gal. From here the stuff is pumped to four constant-level stuff boxes which have return overflows.

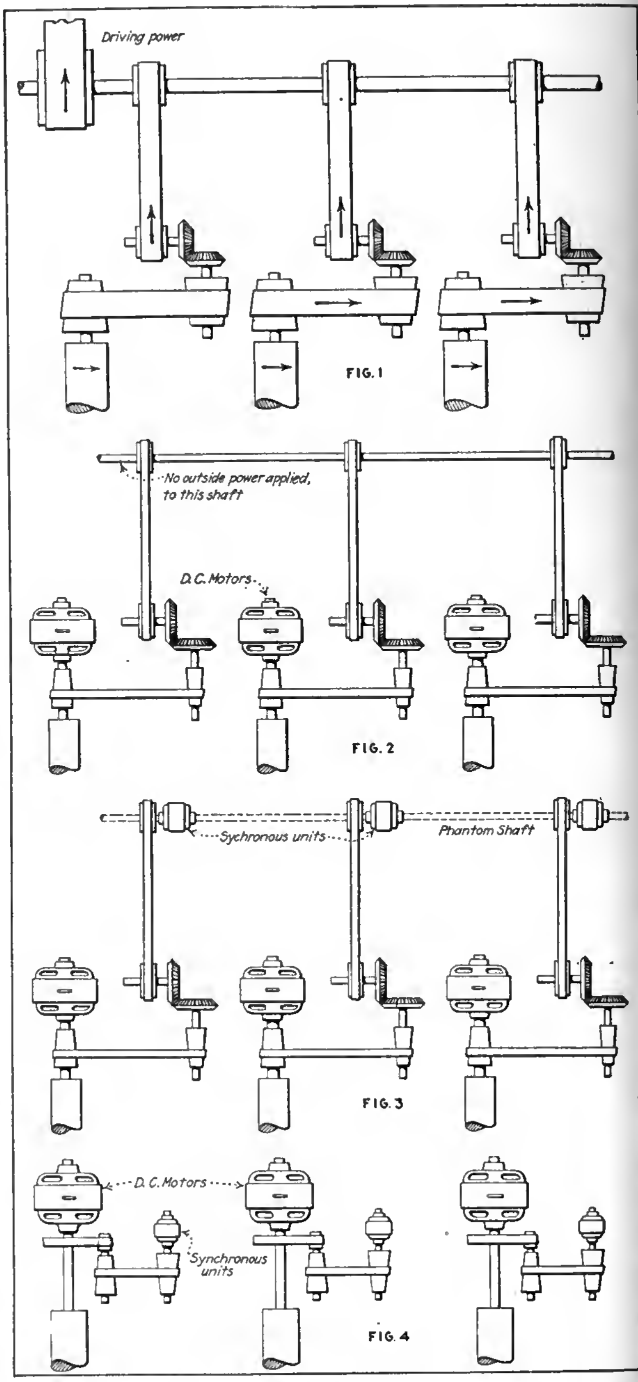
Next in order are the four mixing boxes, where the 1,600-g.p.m. flow is boosted to 14,000 g.p.m. by the circulating white water, about 64,000 tons being passed through the four machines every twenty-four hours. Each paper machine is preceded by three inward-flow rotating Bird screens which remove the last traces of undesirable matter and thoroughly agitate the fibers to insure a uniform quality of paper.

The tailings from the Bird screens go to second screens, where the rejected material is removed by hand and the material passed goes back to the paper machines.

The four Bagley & Sewell 164-in. paper machines are placed side by side in the machine room, which is 175 ft. wide and 320 ft. long. They are driven by the General Electric Company's sectionalized electric drive, using direct-current motors which take their current from a turbine-generator for each paper machine.

### Paper Machines Have Sectional Drive

One paper machine is made up of nine independent sections, which, however, are intimately related as to speeds in linear feet per minute. These speeds, though slightly different for each section, are required to be maintained in precise adjustment in order to produce an unbroken sheet of uniform quality. At a speed of 800 ft. per minute the "stuff," 99½ per cent water, is converted into specification paper containing 10 per cent water in forty-five seconds. It is a race between the



THE EVOLUTION OF PAPER MACHINE DRIVE FROM ALL MECHANICAL TO SECTIONALIZED ELECTRICAL

water content on the one hand and gravity, suction, pressure and heat on the other hand.

The first section is the Fourdrinier wire, an endless belt of fine brass mesh the width of the machine. It runs around two rolls about 50 ft. apart, one of which, the couch roll, is driven by a directly connected motor. The upper surface of the "wire" is supported by a number of small table rolls, and near the couch roll and inside of the couch roll as well are installed a number of suction boxes extending the entire width in which a vacuum of 10 in. to 16 in of mercury is maintained.

A uniform stream of stock about ⅝ in. deep the entire width of the wire belt is poured on with a velocity practically equal to that of the wire. During the three seconds that elapses while passing to the couch roll the greater part of the water falls through the wire mesh

and the fibers are left in a felted sheet, which is further compacted by the forcible extraction of water as it passes over the suction boxes.

At the couch roll the deposited fibers have become paper. This is still 75 per cent water, but it has sufficient strength to withstand the strain of being peeled from the wire, whence it passes over an open space unsupported to the wool-felt-carrying member of the next section, which is the first press.

It can readily be seen that the speeds of these two sections must be adjusted with microscopic accuracy in order that the delicate web may not be overstretched on the one hand or not be carried away fast enough on the other hand. Through the press sections, of which there are four in series (three in use), each with its motor drive, the paper is carried on wool-felt between rollers under heavy pressure. The top rolls are made of polished granite with the pressure further augmented by compounded levers carrying weights. The bottom roll of the first press is provided with a vacuum box. These presses reduce the water content from 75 per cent to about 66 per cent, during which process the strength of the sheet is very materially increased.

The next unit, by far the largest and heaviest of all, is the dryer section, which consists of forty-four finished revolving cast-iron drums each 5 ft. in diameter by 13½ ft. long and heated by the exhaust steam from the turbine. This steam still holds about 88 per cent of the heat that it contained as it came from the boilers. The drums are all geared together and are fitted with a canvas belt having a total length of more than 600 ft. and as wide as the machine, since it must carry the paper. Means are provided for extracting the condensate from the rolls and returning it for boiler feed. The rate and extent of drying is controlled by adjusting the back pressure on the turbine. This section requires two motor drives on account of the great length of the train of gears.

There is also provided an auxiliary alternating-current drive for this section with a large gear reduction which is used for convenience in starting or for low-speed operation of the drives. The combined weight of all the rolls in this section is 375 tons and the starting duty is very high, principally owing to bearing friction. About 15,000 lb. at 1 ft. radius is required to start the section after a shutdown of a few hours. The mass inertia prolongs the starting load, as the 375 tons of revolving parts are made up almost entirely of 5 ft. drums. The section can be started by the direct-current motors alone by a special switching arrangement which puts the two motor armatures in series, thus relieving the load on the turbine generator. The alternating-current motor for starting and running up to 80 ft. per minute allows for the adjustment and renewal of "felts" or repairs on Sunday without operating the 500-kw. direct-current turbine.

*Canadian Westinghouse. †General Electric. ‡Crocker-Wheeler. ‖Canadian Fairbanks.

The paper now goes to the calender, which is made up of ten polished steel rolls in a vertical stack, with a 100-hp. motor directly connected to the bottom roll. The paper goes to the top of the stack and passes in and out between the rolls to the bottom, where it emerges a bright, smoothly finished sheet of paper.

The reel just beyond the calender rolls up the product into units weighing about 1½ tons. While not affecting the nature of the paper, this unit has also to be intimately tied in as to speed with the other sections. The entire course through the paper machine takes about forty-five seconds.

These reels of paper are lifted by means of an electric parallel-motion hoist to stands, from which the paper is run through the slitter, which trims off the edges and slits the paper into two or more parts. The rewinder now rewinds the paper on paper tubes with metal ends that are adapted to the printing presses on which the paper will be used. It is usual to make two 73½-in. rolls, each weighing about 1,400 lb. The rewinder is driven by a 30-hp. motor with speed control by means of a rheostat in the field of an alternating-current-motor-driven direct-current generator in the basement. The trimmings from the sheet and other "broke" resulting from various causes are put through a beater in the basement, which reduces the wet or dry broke to pulp that can be returned to the system at the machine chest.

The commercial rolls are now taken to the finishing

room, where they are securely protected by heavy wrapping paper made from the rejections of the sulphite and ground-wood mill.

### SECTIONALIZED PAPER-MACHINE DRIVE AN ACHIEVEMENT OF NOTE

Sectionalized motor drive for a paper machine presents one of the most exacting and complex of the thousands of special applications of electric motors to industrial arts.

(a) In order to compete it must use less power, must save space and must cost less to maintain than the conventional mechanical line-shaft drive.

(b) In order to operate successfully it must allow for a wide range of speed in paper production. It must be easily adjusted for "stretch or draw" between the sections and must hold that adjustment unchanged either by creepage or hunting. It must enable the operator to slow down or stop any section without disturbing the others. All its members and attendant control features must be sturdy and self-reliant to operate where inspection is possible only at 160-hour intervals.

All these rigid specifications are met on these machines as they have been on many others.

### OPERATION.

The General Electric sectionalized drive is operated in the following manner. In the basement below each paper machine there is installed a 500-kw. direct-current-geared turbine-generator shaft. The line voltage determines the rate of production on the paper machines and is 185 volts for 800 ft. per minute, with a workable range from 500 ft. to 1,200 ft. per minute. This voltage is controlled from the machine room by a chain-operated rheostat in the 500-kw. generator field. The turbine speed and the exciter voltage are held constant.

The motors driving the various sections have their fields energized by the 125-volt exciter. They are large, low-speed units designed for about 150 r.p.m. at 245 volts so as to avoid the interposition of gears. The couch roll and calender stack each take a 100-hp. motor, while the presses each take a 50-hp. motor, the dryer two 100-hp. motors and the reel a 30-hp. and the rewinder a 35-hp. motor, all of the shunt-wound interpole type.

With the exception of the rewinder motor and the second motor on the dryer, each motor is accompanied by a 20-hp. synchronous motor—or generator, as the case for the moment may be—and these synchronous tie-in units are all connected to a common three-wire, three-phase bus to which nothing else is connected. Their fields are energized from the 125-volt exciter. These synchronous units are belted through cone pulleys to the direct-current motors, with the exception of the first dryer motor. In that case the cone pulleys are dispensed with as the speed of this unit is taken as par and the "stretch and draw" of the other sections are regulated to this base speed.

The effect of these synchronous units tied in as they are is similar to that of a great flywheel which can be neither delayed nor hurried. With all the motors running, any direct-current motor and the section it drives may be adjusted as to speed by moving the belt along on the cone pulleys. If the direct-current motor field strength is right, the synchronous unit will be simply idling, as indicated by its ammeter. Should the direct-current motor be inclined to run faster, the synchronous unit becomes a generator giving energy to the other similar units which for the time may be performing as motors. This puts a restraining load on the direct-current motor and effectually holds it in line. Conversely, if a direct-current motor is inclined to slow down, its attached synchronous unit would supply aid as a motor again, effectually holding the section in line.

These guide units can aid or hold back up to 40 hp. each, and by occasional hand adjustment of the direct-current motor-field rheostats these exchanges of loads can be kept near to zero. Little attention is paid to the loads on these units, however, and the meters bear only a center mark and outside limit marks. Any change in the load on one unit affects the other eight by only one-eighth of the change. The belt shifter is brought through to the front of the machine, and the machine tender can change the speed of a section by a fraction of 1 per cent with the assurance that it will hold that place until he makes a further change.

When it is necessary to slow down or stop an individual section, the ordinary drum controller is resorted to, and its first step disconnects the synchronous unit from the common bus. Thereafter the section is controlled in the ordinary manner. After the section is brought up to normal speed the synchronous unit is tied in by

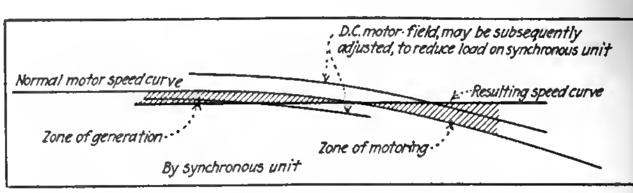
pushing a button at the controller. Should the motor-overload circuit breaker open, it also disconnects the guide unit.

After a complete shutdown, as, for instance, to put in a new Fourdrinier wire, all the sections can be restarted, brought up to speed and tied in as fast as the controllers can be handled. The tying in by the synchronous units does not require any special manipulation, as, being belted to their respective sections, they are always so closely in accord that there need be no delay on their account.

As previously mentioned, the wrapper machine takes the rejected material from the ground-wood screen room and sulphite screen room and converts it into heavy wrapping paper, making about 10 tons in eight hours. The stock passes through beaters and Jordans and then to the wrapper-machine room. The wrapper machine is of the cylinder type and is driven by two motors, one on the constant-speed line shaft carrying auxiliaries and one on the variable-speed shaft driving the paper machine itself. These are both direct-current motors operated by a turbo-generator set which carries 30 lb. back pressure in order that the steam may have sufficient heat to dry this very thick paper.

The shop machinery is driven both in groups through line shafting and with individual motors connected to machines. There are blacksmith, machine, pipe, carpenter and pattern shops and a roll-grinding room fully equipped to handle all routine work of mill maintenance.



RANGE OF MOTOR PERFORMANCE IN THE SECTIONALIZED PAPER MACHINE DRIVE

The lighting of this mill is particularly well distributed and was laid out with a view to economy without sacrificing light where light is needed. There are about 1,200 tungsten lamps averaging 100 watts and actually running from 75 watts to 200 watts. They are fed by open conduits, using condulets for outlets, and are all equipped where practicable with 18-in. white enameled reflectors. The lighting load is about 120 kw.

In this mill, the only one 100 per cent electrified mill in the paper industry, may be found practical applications of electric power in many forms. The pumping of water and stock forms a large percentage of the load, and the combined output of the pumps is about 140,000 gal. per minute. A reference to the diagram showing the water content in the materials as they pass through the various operations will indicate how important these units are. The grinding of wood on such a wholesale plan by electric motors, while not new, is so well worked out here that it is worthy of considerable study. Only in very recent years has it been considered feasible to grind wood other than by direct application of water power. The hundreds of wide scattered auxiliary units of every conceivable type could certainly not be located so conveniently or operated so economically with any other form of power transmission than electric motor drive. Finally, the sectional motor drive of the paper machines themselves is a very fine development of special industrial engineering and works out very much to the satisfaction of the trade.

# Lansing to Have Architecturally Uniform Lighting System

## Plan Whereby Every Paved Street Will Ultimately Be Lighted from Ornamental Underground-Fed Standards—Five Classes of Illumination Adapted to All City Streets

By OSCAR E. BULKELEY
*Superintendent Board of Water and Electric Light Commissioners*

LANSING, the capital of Michigan, will be the first city in the United States to have an architecturally uniform system of street-lighting units. A comprehensive scheme which will provide eventually for the illumination of every paved street by ornamental, underground-fed standards has been adopted, and the first 350 units are now being installed. The lighting plan was formulated by the writer in consultation with illuminating engineers of the General Electric Company and was an outgrowth of a general feeling of dissatisfaction with the existing boulevard lighting system, which is not only poorly designed but inefficient. It was realized that the time was opportune for a change, while the investment in the existing lighting system was still comparatively small, while no great loss would be involved in replacement, and before making a substantial additional investment for extending the system. This was especially true since the contemplated extensions included the most important thoroughfares in the city.

The scheme adopted divides the illumination into five classes according to types of streets and their lighting requirements, as follows: The principal business streets, the secondary business streets, the main boulevards and thoroughfares, the secondary residential streets, the parks, plazas and other open places.

The standards and lighting units on all streets will be of the same architectural family and will harmonize in design with one another and with their surroundings. Thus the distressing variance in types that is so often noticeable where a city's lighting equipment has been acquired piecemeal will be absent in Lansing. On the contrary, a novel and very pleasing uniformity in appearance will characterize the plan.

This installation will be the first in which the design, known by some as the Saratoga unit, will be produced in alabaster rippled glass, this pattern having heretofore been restricted to globes having a diffusing surface. This will give an added element of distinctiveness to Lansing's new system.

### INTENSIVE LIGHTING ON BUSINESS THOROUGHFARES

Intensive lighting will be used in the main business sections of Washington and Michigan Avenues. In these sections standards 20 ft. from ground to light source, carrying two form 12 "Novalux" units with medium alabaster rippled globes and canopies, each equipped with a 10,000-lumen (1,000-cp.), 20-amp. series tungsten lamp are proposed. In the bases of the standards will be installed type IL transformers with taps that will permit the future use of 15,000-lumen (1,500-cp.) lamps. This transformer raises the 6.6-amp. line current to 20 amp. Not only will this provide for the use of the more efficient high-current lamp, but it will effectively insulate the pole from the high voltage of the underground circuit and protect the lamp from line surges. The standards are to be spaced from 110 ft. to 135 ft. apart and opposite each other. At present the business district is inadequately lighted by obsolete cluster-type standards, although there are now installed nearly double the number of standards contemplated in the new lighting system.

Similar units to those just described will be installed along secondary business streets, with the difference that only one unit to a standard will be used. The standards will be approximately 15 ft. from the ground to the light source. On the more important secondary streets and on the principal streets beyond the two-light standards 10,000-lumen (1,000-cp.) lamps are planned. In other locations 6,000-lumen (600-cp.) lamps, with provision for the use later of 10,000-lumen lamps, will be used.

### SPACING OF UNITS AND STAGGERING OF STANDARDS CONFORM TO STREET WIDTHS

The spacing of the units on these secondary streets will vary with the width and importance of the street. On the narrow ones the standards will be staggered, with one every 55 ft. or 75 ft. On wide streets the standards will be placed opposite one another at intervals of from 100 ft. to 125 ft. as this staggering will produce better illumination.

The main boulevards and thoroughfares are the principal routes for incoming and outgoing traffic and hence demand lighting that will make it possible to drive an automobile through them at a moderate speed without the use of bright headlamps. In these installations 4,000-lumen (400-cp.) tungsten lamps in form 8 "Novalux" "Polycase" glassware will be used, mounted on a King Manufacturing Company's standard of French design, providing for a height of 13 ft. to the light source. The spacing will be approximately 100 ft. at street intersections, increasing to a maximum of 140 ft.

Pennsylvania Avenue is an example of a broad boulevard having a grass parkway in the center ornamented

LIGHT DISTRIBUTION CURVE AND DATA ON INTENSITIES FOR A TYPICAL UNIT

with shrubs and flower designs, on either side of which is a paved driveway. There will be a single row of the boulevard-type standards placed on the center line of this parkway. There is, however, a section of this boulevard south of Main Street where trolley tracks will be placed in the central parking. There the lighting standards will be installed along the sidewalk curb, for the reason that if the units were mounted on the double-bracket trolley poles in the parking, there would be an objectionable shadow on the street side of the

BOULEVARD-TYPE STANDARDS LEND ATTRACTIVENESS TO A CENTER PARKWAY WITH SHRUBS AND FLOWER DESIGNS

trolley cars, especially when a car stopped to discharge or take on passengers.

The IL transformer used with these standards will have a tap which will permit the use of a 6,000-lumen (600-cp.) lamp when increased traffic in certain locations necessitates such a change.

For the secondary residential streets the same standard as that to be used for the boulevard lighting, except that it will be a little shorter, will be employed. It will be equipped with the same lighting unit and a 2,500-lumen (250-cp.) tungsten lamp. The standards will be installed at intervals of from 100 ft. to 150 ft. of street.

### Boulevard-Type Lighting for Drives Will Be Utilized

The main park drives will be equipped with lighting of the boulevard type, and minor roads and walks with standards like those used in the residential districts. Plazas, playgrounds, etc., will be considered from the standpoint of their individual needs and requirements and will be lighted accordingly. Each will be treated as a special installation.

The details of this entire plan have been approved, although its realization in the business district will require the active co-operation of the merchants located there.

When the installation is complete Lansing will have more than a modern and highly efficient lighting system. On account of the uniformity of the types of standards and lighting units selected, the general appearance of the city will be greatly enhanced. Clearly, it will be a progressive step toward the "city beautiful" and will harmonize completely with the city plan which was recently developed for Lansing. Furthermore, the plan is elastic in that it provides for the use of more powerful lamps in any of the standards as the future needs of the city may require.

The installation on Pennsylvania Avenue has been completed and is shown in the accompanying illustration. Groups of ten standards each are connected to individual 2.4-kw. type SL transformers which are fed by existing series street-lighting circuits.

### Details of Cable Construction and Installation Costs

A single conductor No. 8 B. & S. boulevard lighting cable for 600 volts service is used. The cable has 1/16-in varnished-cambric insulation surrounded by a lead sheath of 1/16-in. thickness, which in turn is covered with 100-lb. jute yarn not less than 5/64 in thick, thoroughly impregnated with a hot asphaltum compound. Every length of cable was tested for five minutes on an alternating electromotive force of 3,000 volts, and a 15-ft sample of each length was subjected to a test of 6,000 volts. This is the specification for what is known as 1,250-volt cable.

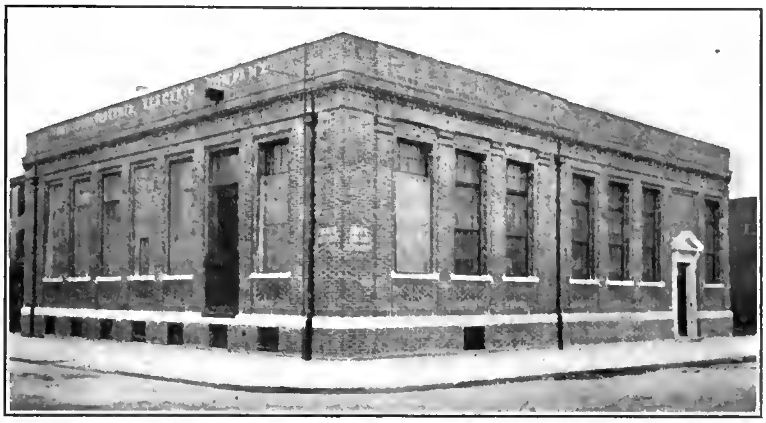
For the installation of eighty-seven of the 13-ft standards, equipped with 400-cp. lamps, the cost for labor is $28.60, material $81, a total of $109.60 per standard. This includes the standard, lighting unit underground cable, type SL transformer and their installation, but does not include any charge for the existing series circuits to which the SL transformers are connected or the constant-current transformers at the station. The cost is considered moderate for so excellent an installation.

# Alternating-Current Substation Design

## Method Adopted for Distribution at 13,200 Volts, Three-Phase, and 2,400 Volts, Two-Phase, Three-Wire—Ample Reserve Capacity and Simplicity in Layout Are Features

By R. A. HENTZ
*Assistant Engineer Electric Design and Construction, the Philadelphia Electric Company*

THE Philadelphia Electric Company has recently put in service two new alternating-current substations to meet the increasing load demand. One of these, known as the Race substation, supplies, along with two older substations, the load of the West Philadelphia residential district. The other substation, known as the Federal substation, supplies, together with an older substation, a combination industrial and residential load in South Philadelphia. These two new substations are very similar in their general characteristics, and a description of one would to a great extent apply to the other. Each is supplied from the generating stations at 13,200 volts, three-phase, 60-cycles, part of the energy being distributed at this voltage and the rest being transformed to 2,400 volts, two-phase, three-wire for other distribution circuits.



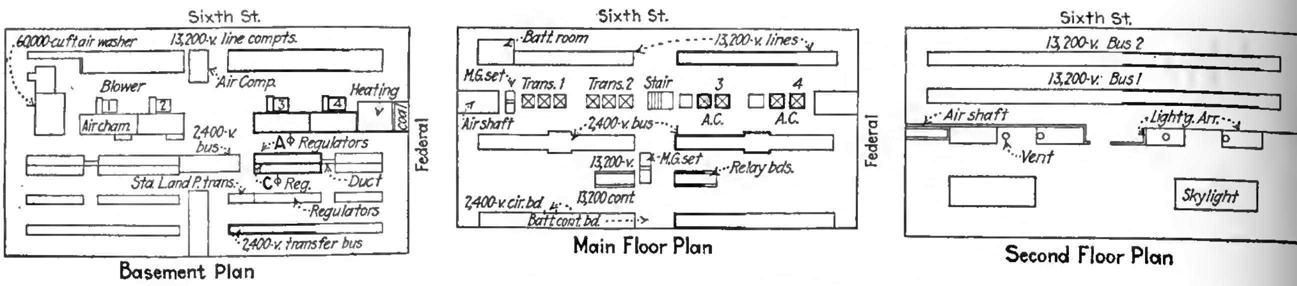
EXTERNAL APPEARANCE OF SUBSTATION HARMONIZES WITH SURROUNDING BUILDINGS

In each substation provision is made for the installation of four banks of transformers, each of 7,500 kva., two of which have been installed and supply the present load requirements. As one of these is a reserve bank, the ultimate rated station capacity is considered to be 22,500 kva. Provision is made in both of the substations for ultimately changing the distribution from 2,400 volts, two-phase, three-wire, to 2,400/4,150 volts, three-phase, four-wire, if it should ever be deemed advisable, at which time the station capacity would be increased 50 per cent by the addition of a third 3,750-kva. transformer to each bank.

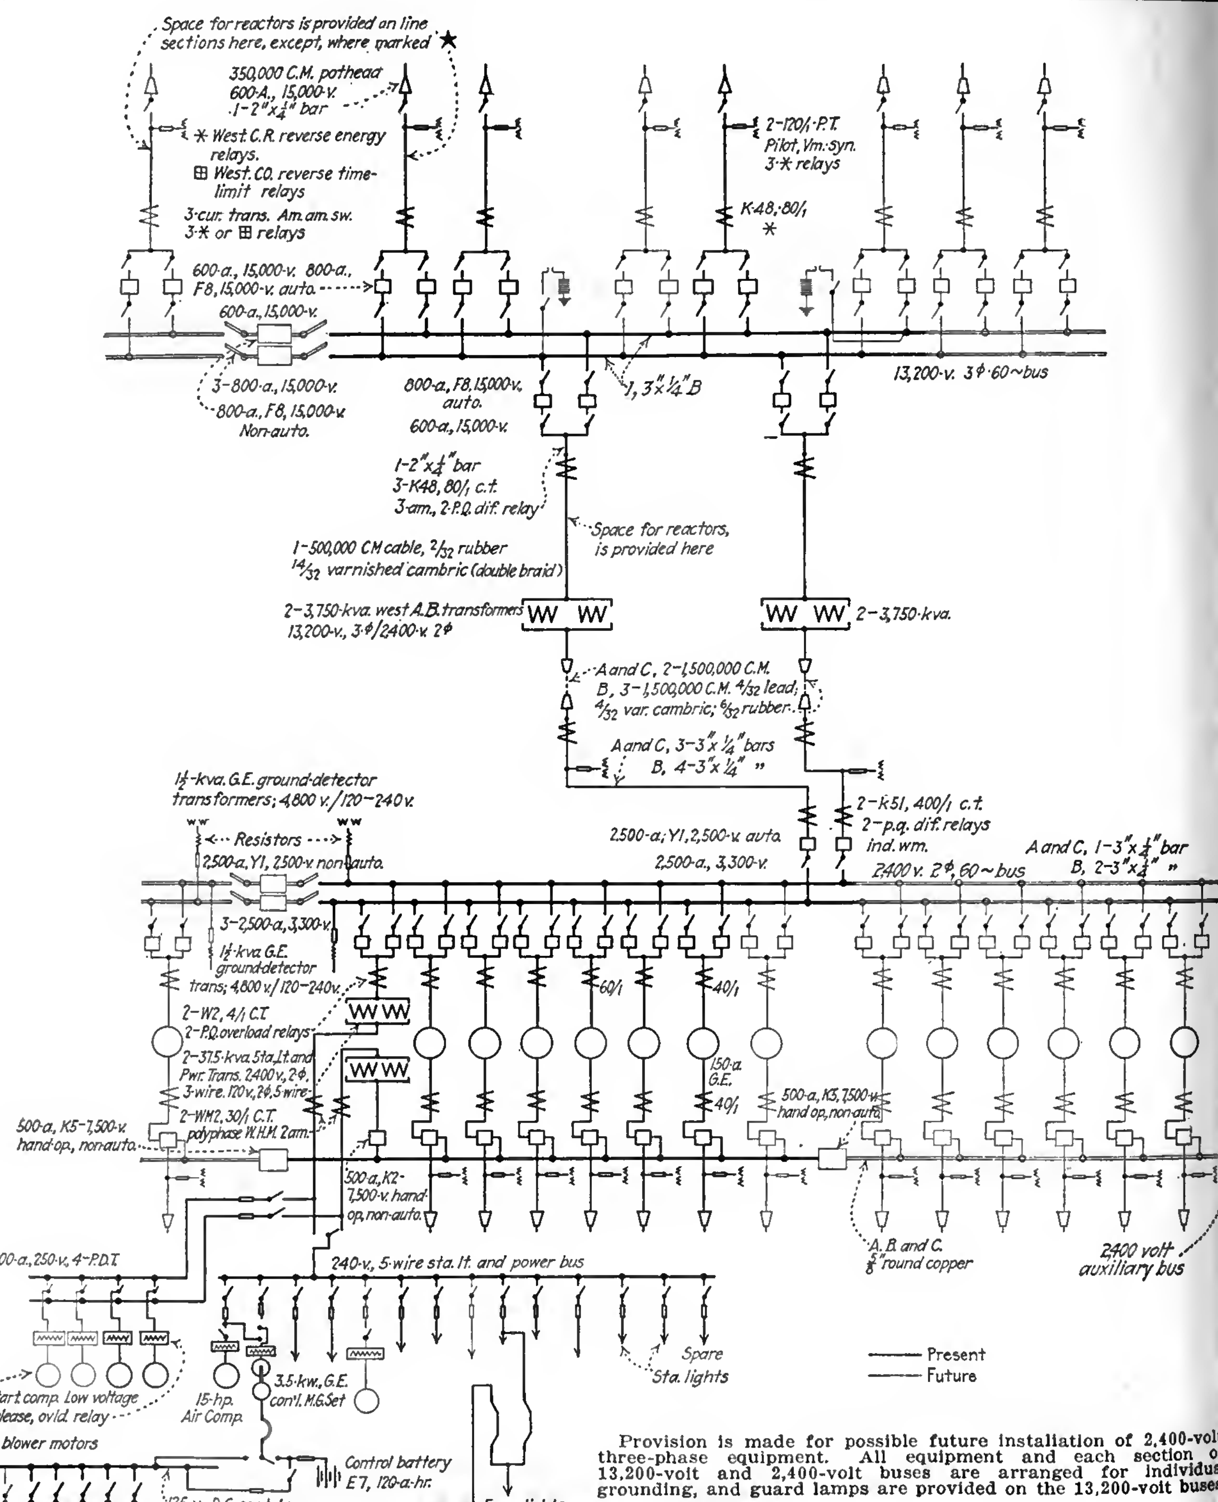
The accompanying single-line diagram and cross-sections indicate the general features of the design of this station. It will be noted that double sectionalized buses are provided on both the 13,200-volt and the 2,400-volt system, thus permitting the operation of the station in four entirely separate groups if desired. Provision is made for the installation of reactors on 13,200-volt lines, the Federal station being designed for reactors on any feeder (incoming or outgoing) as well as on the transformer banks. At the Race substation it was felt that reactors on outgoing distribution lines only would be required, and therefore such provision was made only on every third 13,200-volt section.

There are two oil circuit breakers (one for each bus) provided on each 13,200-volt circuit, switches of the

PLENTY OF CLEARANCE AND PRECAUTIONS TO PROTECT OPERATORS ARE FEATURES OF THE INSTALLATION



FLOOR PLAN OF SUBSTATION, SHOWING GENERAL ARRANGEMENTS



Provision is made for possible future installation of 2,400-volt, three-phase equipment. All equipment and each section on 13,200-volt and 2,400-volt buses are arranged for individual grounding, and guard lamps are provided on the 13,200-volt buses.

ARRANGEMENTS MADE FOR A DUPLICATION OF EQUIPMENT IN THE FEDERAL SUBSTATION

[C]ondit F-8 type being installed at Fed[e]ral and General Electric H-203 type [a]t Race. The incoming lines are pro[t]ected by Westinghouse CR reverse [e]nergy relays and the outgoing by [W]estinghouse CO overload relays.

## [S]COTT CONNECTION USED TO OBTAIN TWO-PHASE

The transformers, which were fur[n]ished by the Westinghouse company, [a]re Scott-connected for three-phase [t]wo-phase transformation and are [p]rotected by double-coil differential [r]elays. In line with the practice [o]f the company these transformers [a]re of the air-blast type. Condit-[t]ype "Y-1" oil circuit breakers rated [a]t 2,500 amp. are installed on the [l]ow-tension side of these transformer [b]anks, and 500-amp. Condit "D-13-B" [s]olenoid-operated oil-circuit breakers [o]n the 2,400-volt distribution circuits. [P]rovision has been made for the instal[l]ation on these circuits of 250-amp. 10 [p]er cent induction regulators. For the [p]resent units of both 150-amp. and [2]00-amp. are being used. Protection is [a]fforded these circuits by instantane[o]us overload relays, and in the Race [s]ubstation an experimental installation [o]f circuit reclosing relays is now being [t]ried out. It provides for the immedi[a]te reclosing of any circuit that has [t]ripped a given number of times (prob[a]bly three), after which the oil circuit [b]reaker will remain open. If the short-[c]ircuit current at times of initial or [a]ny subsequent opening is excessive, [t]he reclosing equipment will be ren[d]ered inoperative.

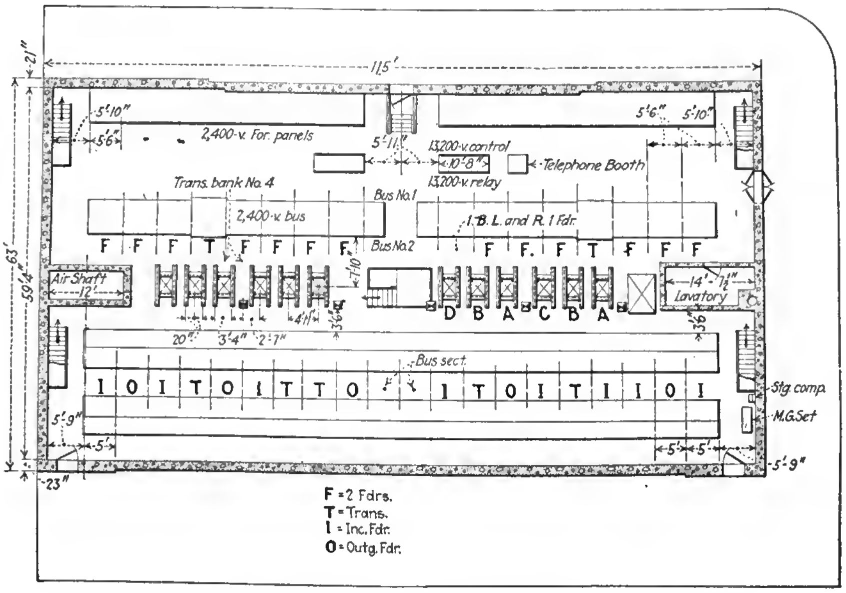
A transfer bus is provided whereby any distribution circuit can be transferred to the section supplying any other circuit in event of a failure of the oil switch or regulators of the first circuit. This transfer bus is sectionalized into four parts.

The station power and lighting supply is obtained through two 75-kva. transformer banks, one being a reserve. They supply the four motors driving the 12,000-c.f.m. Sturtevant No. 75 "Silentvane" blowers, a 100-c.f.m. Worthington air compressor, a 3½-kw. control motor-generator set, a sump pump and station lighting. The control, which is 125 volts, is supplied from the above motor-generator set which floats across a sixty-cell Electric Storage Battery Company "E-7 Exide" storage battery.

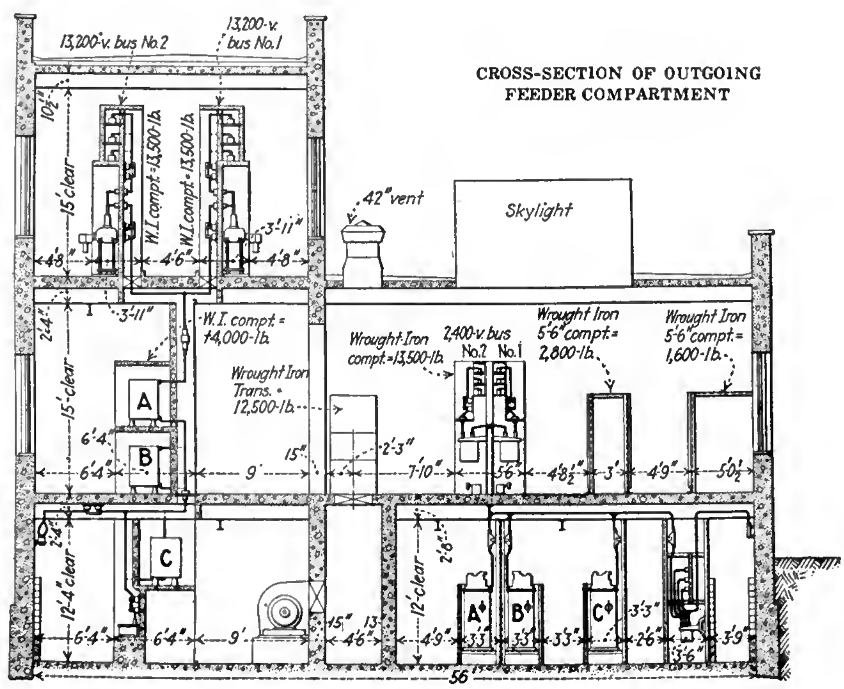
## SPECIAL FEATURES OF DESIGN

Among the features incorporated in the design of both of these stations may be mentioned the following:

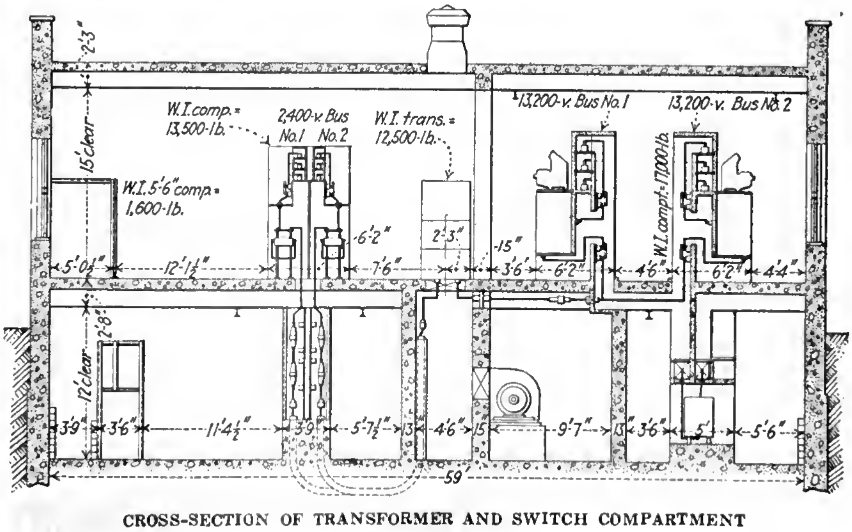
1. All 13,200-volt compartment doors



MAIN FLOOR LAYOUT WITH DIMENSIONS



CROSS-SECTION OF OUTGOING FEEDER COMPARTMENT



CROSS-SECTION OF TRANSFORMER AND SWITCH COMPARTMENT

are locked in order to make it impossible for any maintenance or construction men to get into any of these compartments without the knowledge of the station operator, who alone carries the key. When the particular compartment to be worked on has been blocked and opened, locks on all other compartments, which are exactly similar in appearance, prevent the unwary man from getting into them in error.

2. The 13,200-volt sections are provided with what are known as disconnecting switch guard lamps. These lamps, inserted in the compartment walls near the disconnecting switches, are controlled by the oil-switch mechanism and indicate by being lighted that the oil switch is open and that the disconnecting switches may be pulled, thus minimizing the chance of the operator accidentally opening a disconnecting switch under load.

3. A very effective system of marking the individual

RACE SUBSTATION WAS COMPLETED IN 104 DAYS

compartments, both 13,200-volt and 2,400-volt, is provided. This consists of small metal targets which project from the compartment barriers, indicating the line dividing one feeder section from another. The separation of circuits is further emphasized by painting broad red lines between sections.

4. Telephone drop signals are installed which indicate any occurrence that should be brought to the immediate attention of the operator, such as tripping of any transmission or distribution lines or transformers, failure of air pressure on transformers, etc. A small ball which normally shows a black face rotates so as to show a red one, at the same time ringing a distinctive bell which cannot be confused with the door or telephone bells.

5. All 13,200-volt and 2,400-volt lines enter and leave the stations underground, and where the circuits are aërial connections are made to the lines at nearby terminal poles. The ducts inside of the substation are flexibly arranged so that cable in any one of them can be brought to any compartment.

6. In order to facilitate the work of the underground department in installing new cables or repairing damaged ones, arrangements are made so that any of the three leads from the pothead can be very easily connected to either of the three jumpers which extend to the oil switches and bus, thus allowing the underground department to make its cables splices in the best possible way, irrespective of phases, the cables being finally phased out in the substation where the correct connections are made.

7. The psychology and economy of a bright, cheerful station is recognized in the design, and ample windows and skylights flood the entire station with daylight. The walls (above a man's height) and ceiling are painted dead-white.

### Future Expansion Made Possible

It may be of interest to note that work was started at the Federal substation by the demolition of an old church building on June 5 and the station finally put in operation on Oct. 22—118 working days being consumed from time of starting to completion. At the Race substation, which is slightly smaller on account of the fewer number of reactors provided for on 13,200-volt lines, work was started on June 26 and the station put in service Oct. 29—104 working days being consumed. As can be seen from the photographs, these stations are of a pleasing appearance and constitute a desirable addition to the neighborhood.

In both cases only about one-half of the ultimate building was erected, which allows for the installation of seven 13,200-volt lines, two transformer banks and fourteen 2,400-volt distribution circuits. These sections will care for the load served for a few years to come, thus postponing a heavier investment in building until such time as it is actually required.

## Bureau of Mines Cites Advantages of Electric Brass Melting

THE theoretical advantages of electric brass melting are summarized by the United States Bureau of Mines in one of its recent publications as follows:

1. Melting may take place in a neutral or reducing atmosphere, thus minimizing loss of metal by oxidation and improving the quality of the product through freedom from oxides.

2. Metal of crucible quality may be obtained without the use of crucibles.

3. Melting may take place in a tightly closed chamber, or at least in one free from the constant passage of the products of combustion of fuel, and thus losses of volatile metals such as zinc and lead may be reduced. Contamination by sulphur from fuel is avoided and a better product obtained.

4. In some types of electric furnaces the temperature may be more readily controlled than in fuel-fired furnaces.

5. In some types of furnaces the molten metal is thoroughly stirred, thus giving a uniform product, even with large heats.

6. There is no handling or storage of fuel, such as coke, coal or oil, and no ashes have to be removed. The cost of power can be accurately predicted over longer periods than the cost of fuel.

7. Working conditions about the furnaces are less dangerous to health and safety of workmen, provided that suitable types of furnaces are chosen.

8. The above advantages may be obtained in furnaces of larger capacity than can be used satisfactorily in the fuel-fired crucible types, with resulting greater uniformity of product, lower labor cost and increased production.

# How 2,214 Old Houses Were Wired

## Preliminary Survey of Territory — Formulation of Sales Plan — Organization of Employees Into Selling Force — Total Cost of Six Weeks' Intensive House-Wiring Campaign

By RALPH G. WEBBER
*Central Maine Power Company, Augusta, Me.*

IN A TERRITORY such as that served by the Central Maine Power Company, comprising more than 140 cities, towns and municipalities scattered over an area of several hundred square miles, there are bound to be a good many unwired houses along the lines. Last year it was decided to put on a campaign to connect these houses to the lines at the least possible selling cost and without making a heavy investment in extensions.

The company had no definite records of these unwired houses, and to see what sort of campaign could be worked out a survey was first made. The superintendent of each of the company's twelve districts was asked to make a close estimate of the number of unwired homes in his territory which could be reached by a service loop or by setting one pole. By riding around the streets and roads and in some cases making estimates it was learned that there were more than seven thousand unwired homes right along our distribution lines which were without electric service. What a splendid field for more and better business! Here were our logical customers burning odorous oil lamps right under our noses.

### The Plan of Attack

With this information it didn't take us long to decide that the main attack of our advertising plan would be "direct by mail." Inasmuch as the superintendents had proved to their own satisfaction that they had a lot of unwired homes in their fields, it was a fairly reasonable request to ask them to furnish the head office with the names of the occupants of these homes. Blank "prospect" cards were sent to every superintendent with the request to furnish the name of the occupant of each unwired house and to state whether he or she was the owner; also, the street and number of the house and whether the house could be served with a service loop or by setting one pole.

While this information was being gathered, we formulated the sales plan, devising ways to put our offers before the "prospects" and the most practical way to reach them by personal salesmanship.

In order to give a visual example of what could be bought for certain prices, four popular-priced combinations were made up to be installed by the company's own crews of inside wiremen. They were listed as follows:

1. *Combination at* \$15.—Flatiron outlet and ceiling outlet for kitchen; entrance, ground and complete installation ready to use. Easy terms of \$5 a month.
2. *Combination at* \$25.—Three fixtures, one each for the kitchen, dining room and sitting room, to be installed on one floor; all complete, ready to turn on the lights. Terms, \$5 down, \$5 a month.
3. *Combination at* \$33.75.—Single drop lights for kitchen and hall; two-light fixtures for dining room and sitting room. Terms, \$8.75 down, \$5 a month.
4. *Combination at* \$50.—Drop lights for kitchen, hall and two upstairs bedrooms; two-light fixtures for living room and dining room; complete equipment ready to use. Terms, \$10 down and \$5 a month.

These four combination offers were illustrated and described on a four-page folder (5½ in. x 8½ in.) folded twice to go into a standard No. 5 government envelope.

To drive home the message of electrifying the home, two series of three letters each were written. One series was worded for the home owner, the other for the renter. As the prospect cards carried information as to whether the occupant owned or rented the house, it was an easy matter to separate the cards and have the correct series mailed to each class of occupant. The home-owner series of three letters all emphasized the advantages of electricity, the low prices and the popular combinations.

The first letter was addressed to the woman of the house, the second to the head of the family, while the third did not particularize. With each letter a booklet or folder was inclosed. With the first letter a folder illustrating various electric appliance needs was inclosed, with the second the booklet "Electricity in Your Home" (issued by the N. E. L. A.), and with the third went the folder illustrating and describing the special offers. The series attempted to present a climax in buying appeal. The appliance folder portrayed the "by-advantages" of electricity in the home; the N. E. L. A. booklet showed the elegance, luxury and convenience of the home electric, and the third brought it "down to cases" and showed just how any family that could spare from \$15 to \$50 could have electricity.

To drive home the sales message with sledgehammer force the three letters were mailed out at intervals of every other day—the entire series in six days. Three letters on the same subject, from the same company, it was thought, ought to be enough to force favorable attention. They were. With the first and last letters in the series a return post card was inclosed which asked a representative of the company to call.

### Renters Present a Different Problem

In approaching the occupant of a rented house the sales problem was entirely different from that encountered in soliciting business from the occupant who owns his home. The landlord in Maine apparently figures on doing just as little as he can in the way of repairs or betterments and charging as much rent as the tenant can bear. The tenant appreciates the situation and is reluctant to approach his landlord, well knowing that \$50 worth of improvement may mean a \$5 raise in the monthly rent.

The series of letters aimed at this class of prospects was written with the idea of bringing the renter and owners together on some sort of a working basis. With the owner the point was made that vacant houses were

becoming more numerous and that the owner of improved property would be able to get first choice of tenants. One of these letters is reproduced.

### General Advertising

Although it was fully realized that newspaper advertising would shoot wide of the mark, it was thought best to tie in the direct mail campaign with general publicity. Accordingly, when the campaign opened, the fifteen-dollar combination offer was featured in the papers throughout the territory. Near the close of the campaign one other advertisement was used to remind prospects that they had only a few days more in which to take advantage of the cut in prices. In addition every window of our thirty-two stores in some way carried the message to electrify. All our motor trucks throughout the territory carried banners with appropriate slogans.

*(Form Letter Addressed to Landlords)*

**Isn't It Worth While to Keep Your Property "Up"?**

Have you noticed the general tendency toward increased building activity?

The opinion seems to be gaining ground that instead of a housing shortage we shall soon be facing a housing surplus.

Roger Babson, the famous business observer, feels that there is now a pronounced drift toward an oversupply of new "rents."

Under such changed conditions won't old and unimproved dwellings be hard to rent? Won't tenants be more apt to pick the improved buildings?

Shrewd landlords are apparently anticipating these conditions by improving old dwelling places so that they can compete with the new ones.

Electric service is one of the first improvements installed. Nothing else can add a like comfort to the home. One of the first questions that home renters ask is: "Has the house electric lights?" Electric service means not only lights but electric irons, fans, appliances for cooking and vacuum cleaners.

To the tenant these electric comforts mean satisfaction, convenience, a pride in the home and a willingness to pay the rent cheerfully.

To the landlord "electrified rents" mean improvement of property, keeping the property on a par with that of other "rents" that do have all such conveniences, a greater ease in renting, and the opportunity to ask a greater rental.

During the next few weeks you will have an opportunity to wire your property at special low prices—the lowest prices since 1916 or 1917.

If you wire up now, you will increase the value of your property and make your tenants too comfortable to think of moving.

The inclosed postcard will bring a representative to explain the special wiring proposition that we are now making.

Central Maine Power Company,
George S. Williams,
General Superintendent.

The fundamental secret in achieving success in the campaign lay not in the series of letters, not in the popular-priced offers, nor yet in any magic of the printed word, but in real "honest-to-goodness," face-to-face salesmanship. Left to their own fate, the letters would have made but a slight impression on the persons in the seven thousand unwired homes. Of the post cards inclosed with the letters only about 1 per cent were returned. No organized sales force was in operation, districts were widely scattered, employees knew little or nothing of the company plans. So, to make the publicity really forceful, a campaign of education had to be carried out among the employees themselves. Employees had to be "sold" on the campaign just as thoroughly as the prospects. To do this the company took every employee into its confidence, told exactly what the plans were and how it expected to proceed to achieve results.

First in the series of publicity matter directed toward the employees was an issue of the company house magazine, *The Exciter*, which was devoted almost entirely to an explanation of the campaign. In a straightforward story we told the employee that his success and that of the company were one and inseparable. We pointed out that his bread and ours were buttered on the same side. The machinery of the campaign was explained and a simple sales talk on house wiring was published.

By the time the issue of *The Exciter* was in the hands of the employees a series of district meetings was started. The superintendent of each district was asked by the general superintendent to assemble his metermen, inside wiremen, clerks and all others who could be spared for soliciting to listen to an explanation of the plan. At the district meetings the series of prospect letters was shown to the employees. The function of each letter was explained, as was the ease with which a sales talk could be made.

As part of every combination offer of $25 and more a free flatiron was included. The gift of the iron was reserved for the salesman to make. If, after the regular sales talk had been made there was any hesitancy to sign the contract, the salesman was instructed to say:

"Mrs. Jones, if you will take this combination now, I am authorized to make you a present of a regular 'six-seventy-five' flatiron." It proved to be a good "clincher" for the sale.

In a great many cases the contract could be closed without resorting to the offer of the iron. In such cases the flatiron was included as a gift of appreciation "in order that the new customer might more quickly learn some of the advantages of having electricity in the home."

### Quotas Promote District Pride

In order to get a fair basis of comparison of the work done by the different districts the number of unwired homes, as previously determined by the superintendents, was set up as a quota or bogey. Each district in this way was put on as near an equal footing as an accurate count of unwired homes could make it.

Pride of district in most companies is as potent a stimulus to sales as pride of country is to patriotic effort. And nothing stimulates sales effort more than a few prizes. As a final incentive to action, three prizes were offered—$50, $30 and $20—for the three districts which should score in one-two-three order in percentage of quota sold. Fifty dollars was also put up for reward of individual selling records.

When the series of letters had been mailed to prospects and when all the employees had received their instructions real action began. A telegram or telephone message was sent to every superintendent to start his work of solicitation. Every district started at scratch on a given date.

The campaign was scheduled to continue for a month. The big problem was to see people as fast as the letters were mailed. Speed was urged and in part maintained by frequent bulletins, telephone messages and telegrams to all districts showing the progress of the campaign

The standing of each district was figured, and at times various sales suggestions were incorporated in the bulletins. Interest and enthusiasm were thus kept at a high pitch.

It would not be true, however, to say that every district jumped into a run at the start. On account of lack of solicitors some districts lagged behind. Help was sent to these districts in the form of a flying wedge of salesmen. Ex-wiring solicitors and salespeople recruited from other departments were routed from district to district, as the need required, to stimulate and help the campaign.

At the end of four weeks the campaign had netted 1,200 contracts and showed no signs of diminution. The time was accordingly extended two weeks, by the end of which a total of 2,214 contracts had been obtained. This represented sales of 34.9 per cent of the possible estimated business. The district selling the greatest percentage of its quota reached 66.6.

At the close of the campaign the company had nearly two thousand contracts on its books. This condition presented still another sales problem. No matter how long a person had lived without electricity, as soon as he had decided to buy he wanted the lights instantly.

In order to hold the business a letter was sent about a month after the close of the campaign to customers whose wiring would be delayed. In this letter it was explained that the company's offer had been so popular that wiring crews were swamped with work. As a result of this letter and with a little explanation on the part of the local superintendent not a contract was canceled.

In giving 2,214 as the total number of contracts obtained it is only fair to say that in it is included the ordinary growth that would come without extra solicitation, as well as a few contracts brought in by contractor-dealers.

### CAMPAIGN COST ABOUT $1,800

The cost of advertising, soliciting, prizes and all other expenditures of the campaign was less than $1,800. The contracts for wiring which the company executed brought in gross business of $80,000 and put an added load on the company lines that will bring in an annual revenue of not less than $25,000. In passing it might be noted that most customers selected the fifty-dollar combination plus additions which would average $60 or more.

In the plan of campaign as outlined here there is nothing that any central-station company with a number of unwired houses along its lines ought not to be able to do with good results. Every company has meter readers, stock clerks, wiring solicitors and stenographers. They can be made into an efficient sales force, if it is made easy for them to sell, by offering attractive prices, and by paving their way with advance advertising matter. About all that was new in the Central Maine campaign was the application of old ideas to a new selling plan. Intensive use of the mails, low-priced combination offers, personal selling under a quota basis, easy time payments and the free gift of a flatiron were the outstanding points.

# December Output Over 5,000,000,000 Kw.-Hr.

## Total Gross Revenue from Sale of Energy During Last Month of 1922 Was $107,600,000, an Increase of 6 per Cent for Twelve-Month Period

REPORTS received by the ELECTRICAL WORLD for the month of December from central generating and distributing companies representing 77 per cent of the installed generator rating of the country indicate that four new records were established by the industry during the month. The total sales of energy during the month was 5,200,000,000 kw.-hr., which exceeded the former high monthly figure, set during November, by 5.4 per cent. In addition, the average daily output was 167,958,000 kw.-hr., which exceeded the previous record, also made during November, by 4,738,000 kw.-hr. The second set of record figures reported by the industry for the month of December is to be found in the revenue received from the sale of energy. The total gross revenue from the sale of energy was $107,600,000, which exceeded the former high monthly revenue, reported during November, by 6.3 per cent. Moreover, the average daily revenue from the sale of energy during the month was $3,474,000, which exceeded the former record, made during November, by $101,000.

It must be remembered in studying these data on central-station output that they do not represent the actual amount of energy consumed during December, but the amount of energy actually sold by various distributing companies, some of which was sold to other public utilities for resale and so is counted twice in the resulting tabulation. Similarly, the gross income does not represent the amount paid to the central-station companies by the actual consumers of electrical energy generated during the month, but includes also payments made by one public utility to another public utility for energy which was in turn resold to the actual consumer. Both these transactions are necessarily included in the ELECTRICAL WORLD tabulation as representing the actual operations within the industry.

Expressing the financial phase of the returns in terms of the operating ratio, or ratio of operating expenses to gross revenue from sale of energy, shows that the net earnings per dollar spent for operation and maintenance were less than reported for December, 1921. The operating ratio reported for December, 1922, by companies having steam plants only, taken in the aggregate, was 49.3 per cent, against 48.3 per cent for De-

TABLE 1—CENTRAL STATION RETURNS FOR THREE MONTHS

cember, 1921. This increase is undoubtedly due in large measure to the higher cost of coal this winter than last winter. Although in July, 1922, the operating ratio for the same companies was 55.3 per cent and in August was 56.6 per cent, such a decrease in operating ratio between winter and summer months is to be expected on account of the relatively higher percentage of low-revenue industrial energy sold during the summer months.

Every section of the country except the South Central States reported energy consumption over that of November. In New England the cotton mills reported a record number of active spindles, calling for increased energy consumption. The Atlantic Section reported by far the largest increased energy consumption over November. This was probably a reflection of the continued growth in pig-iron production, which during December was almost double the production reported for December, 1921. A high degree of activity in the Southern cotton mills also added to the energy consumption of the Atlantic section. Energy demand in the North Central section appears to have been almost the same as during November, despite the advancing season and consequent increased lighting requirements.

## Great Susceptibility to Electric Shock in Panama

ONE of the peculiarities of Panama is the deadliness of electricity in that region. Voltages of 110 to 220 in former days repeatedly caused fatal accidents. Since construction days on the canal the Government has provided ample safety appliances, and few deaths now occur notwithstanding that all operating equipment on the canal except the Panama Railroad is electrically driven.

The reason for the abnormal susceptibility to shock, explains R. Z. Kirkpatrick, president of the Engineers' Club of the Canal Zone, is probably climatic. Almost daily precipitation keeps shoe soles moist and standing places are likely to be damp. Again, the temperature and humidity of the air are such that perspiration is almost constant, giving an excellent chance for the full transmission of current on contact. Another point is that physical vitality is lower in the tropics and electric shock is therefore more easily effective in stopping the action of the heart.

In four cases of electrocution Mr. Kirkpatrick personally saw in the Canal Zone, with no voltages above 500, prompt efforts at resuscitation failed.

TABLE II—CENTRAL-STATION RETURNS BY SECTIONS OVER A THREE-MONTH PERIOD

## Letters from Our Readers

A Place Set Apart for Suggestions, Comments and Criticisms, to Which All Men of the Electrical Industry Are Cordially Invited to Contribute

### National Aspects of Niagara Falls Developments

*To the Editors of the* ELECTRICAL WORLD:

It is a fortunate thing that the complexity of electrical engineering problems is so generally recognized that there is little danger of the disastrous results which would ensue were those who had not given the subject sufficient study to undertake their solution. It is unfortunate that the far greater complexity of the problems of economics and sociology is generally ignored. This tendency is well illustrated in an otherwise able article by Frank G. Baum in the ELECTRICAL WORLD of Jan. 27, 1923, by the following extracts:

"To attempt to find a local demand for the whole of these large [hydro-electric] powers, as was done at Niagara, . . . is uneconomic and unsound for the industry and from a standpoint of national stability. For to be stable we should have the industries of the country diversified and spread out over the country as much as possible, building up the smaller communities as well as the large centers. At present places like Niagara . . . have much cheaper power than obtains in the smaller cities and towns. This does not make for a healthy growth of the states and nation. We need a transmission system which will take the power from the large producing centers and more nearly equalize power conditions in small and large cities. . . . It is not sound practice to allow all the water powers of Niagara to be used locally to the advantage of a few industries, but part of the power should be required to flow out into the smaller cities to help them prosper. . . . In that way we will spread out the advantages of water power among more people, and this will in turn create a more favorable opinion for the logical development of water power and transmission systems to meet the needs of the states and the nation."

Passing over the rather absurd implication that there are no transmission lines in the Niagara district and without attempting to analyze Mr. Baum's solution of the complex economic and sociological problems involved in the use of hydro-electric power, it may be worth while to point out a few elementary facts which must be considered before even an approximation of the true solution is arrived at.

Starting with the assumption that it is desired to "spread out the advantages of water power" as widely as possible among the people, the problem is: How can this be done? A superficial view might lead to the solution offered by Mr. Baum—the building of transmission lines which will distribute the hydro-electric power over as large an area as possible. But the recognition of the complexity of a problem of this kind should serve as a warning that a superficial study will not yield the true solution. Now, while it may be perfectly true that the solution of the problem found by the Pacific Gas & Electric system in California is a good one, it does not follow that a different solution at Niagara Falls is a bad one, because the conditions are by no means the same in the two places. Indeed, a study of the results shows that the Niagara Falls hydro-electric development has been more successful in finding a way to spread out the advantages of water power than has the system in California. This does not by any means mean that the Californian development is subject to adverse criticism, because the more widespread distribution of the benefits which can be derived from Niagara Falls is due in great part to geographical conditions. While a large proportion of the water power of Niagara—not by any means all, as Mr. Baum implies—is used locally in the form of electrical energy, the ultimate advantages of this use are spread all over the United States, and indeed the world, and are not confined, as the superficial investigator might suppose, to a few industries.

The mischief is that many farmers, dwellers in small towns and villages, and even some electrical engineers, cannot see how the energy of Niagara Falls can be made to benefit the people except by an electrical transmission line. These critics do not complain of the concentration of the blast furnaces about the great coal fields of the United States, they do not deplore the use of coal by the blast furnace as an unsound practice followed for the advantage of a few local industries. They realize that it would be the height of folly to insist on the distribution of the coal over the country so that every village and small town could run its own blast furnace, for they know that it is to the advantage of the whole country that iron and steel should be produced where they can be manufactured most economically. But our critics do not realize that the country needs ferro-alloys, abrasives, fertilizers, chlorine and the hundreds of derivatives of electrochemical and electrometallurgical industry which cannot possibly be manufactured as cheaply as they are now unless they are near the source of a great hydro-electric plant, and that this in turn must be within economical distance of the places where the products are used. In other words, they are unable to see any method of distributing the advantages of a water power like Niagara Falls except by means of a 220,000-volt transmission line. Yet when the fruit grower of California is destroying insect pests, which otherwise would ruin his crops, with cyanide; when the cotton grower is fertilizing his fields with cyanamide; when the health statistician files his figures showing the enormous decrease in typhoid fever throughout the United States or in the Panama Canal district due to the use of chlorine in purifying drinking water; when the farmers in all our great farm lands drive their tractors and the passengers travel in coaches, running on rails, drawn by locomotives, all built in great part of steel manufactured with ferro-alloys and fashioned with artificial abrasives; when the miners going down into the mines, and thousands of families in isolated places where there is no gas and no electricity, light their acetylene lamps—they are realizing consciously or unconsciously the advantages of Niagara Falls.

It would be impossible in a short space to consider even briefly the economic and sociological reasons which fully justify the large use of hydro-electric powers like that of Niagara for electrochemical and electrometallurgical industries and to show that this use does not involve fostering a few favored manufacturers at the expense of the states and the nation; but this brief note may at least do something toward arresting dangerous misconceptions which are apt to be formed in the minds of the people by a careless *obiter dictum*.

Niagara Falls, N. Y. FRANCIS A. J. FITZGERALD.

# Central Station and Industrial Practice

Installation, Operation, Maintenance, Test and Repair of Generation and Distribution Equipment, and Methods of Economically Utilizing Electric Service in Large Industrial Plants

## Economy in Furnace Wall Construction

MODERN boiler-room practice imposes duties on furnace walls and linings that were formerly considered impracticable. Consequently the quality and manner of installing these linings is receiving well-merited attention. The purchase of high-grade refractories is a good investment, but the conditions under which different parts of the furnace will operate should be studied.

For example, a survey of the interior of a furnace in active operation, which may readily be made with the aid of an optical pyrometer, will disclose certain "hot spots" that explain why some grades of firebrick do not stand up well under service. One such survey recently made on a furnace disclosed a temperature in excess of 3,000 deg. F. over a horizontal zone, about in the center of the side walls of the combustion chamber and the rear bridge wall under the mud drum of a Stirling boiler. The temperatures shaded off to about 2,400 deg. on either side above and below this point. Other parts of the same furnace at the same time were operating at temperatures below 1,800 deg. This furnace will be relined with at least two grades and possibly three grades of firebrick.

Considerable trouble is sometimes experienced with chipping or spalling. This may be caused by unequal expansion of the brick, especially in stand-by steam plants on a hydro-electric system where rapid changes of temperature due to sudden changes in load are encountered. The writer has had experience with a number of Dutch-oven furnaces in the steam stand-by plants of the Portland Railway, Light & Power Company, where sawmill refuse is burned. In these large flat-arch tiles are hung. These tiles were laid about ¼ in. apart with high-temperature cement between them, but only in the outer half of the joint, the inner half next to the fire being left open. Since the inner face of the tile was subjected to more rapid changes in temperature, it expanded and contracted more rapidly than the outer portion. The open joint permitted this expansion to take place freely, with the result that after two years' use under the most extreme conditions of stand-by service only one tile has lost its edge, and this was caused by the careless handling of a firing tool. The accompanying halftone shows the appearance of this arch when first installed and indicates quite clearly the open joints between the faces of the tile.

CHIPPING AND SPALLING OF FURNACE BRICKS PREVENTED BY LEAVING ¼-IN. OPENING BETWEEN FACE OF BRICKS IN FURNACE ARCH

Another detail in connection with this arch construction has resulted in lower maintenance costs. The main I-beams holding up the arch extend beyond the brick side walls and are supported by steel channel columns erected against the outside furnace walls. These channels bear the entire weight of the arch, relieving the outside walls from any stresses except those due to their own weight. The two years' service from these furnaces have shown the side walls to be in a much better state of preservation than is the case with furnaces where the side walls carry the entire weight of the arch. This form of construction also permits any part of the side walls to be removed for repairs without disturbing or shoring up the arches.

H. S. BASTIAN,
Assistant Engineer.
Portland Railway, Light & Power Company,
Portland, Ore.

## Motors and Appliances in Dusty Places

SEVERAL important revisions of clauses in the National Electrical Code relating to the protection of motors and appliances in dusty locations have been recommended by the electrical committee of the National Fire Protection Association. These proposed changes after final revision are to be incorporated in the 1923 edition of the code and are given in part below:

Rule 8 (f), amend to read:

"Motors having brushes or sliding contacts exposed to combustible dust must be placed in separate dust-tight rooms, or non-combustible housing pro-

vided with effective ventilation from a source of clean air.

"In places where combustible dust is thrown into suspension in the air in sufficient quantity to produce explosive mixtures, such as in flour mills, grain elevators, etc., or where it is impracticable to prevent dust or flying materials collecting in dangerous quantities on or in motors, all motors shall be either of the totally inclosed type or shall be placed in separate dust-tight rooms or non-combustible housings. Such rooms or housings shall be effectively ventilated from a source of clean air."

Rule 31 (a), amend to read:

"In places where combustible dust is thrown into suspension in the air in sufficient quantities to produce explosive mixtures, dust-tight fixtures inclosing lamps and sockets shall be used. Such fixtures should be supported by conduit hangers or chains to prevent any strain on the wires. Wires should have rubber insulation not less than $\frac{3}{64}$ in. thick."

Rule 25 (a), paragraph to be added: "Electric heaters shall be so located that dust or flying material will not collect on them in dangerous quantities."

## Automatic Voltage Regulation for Generators

THE type KR system of automatic voltage regulation employs a booster which can be inserted in the circuit between the generator field and the individual exciter or the excitation bus. The field of this booster is supplied from a booster exciter, whose field in turn can be varied automatically not only in strength but in direction, having a continuous range from a maximum positive to a maximum negative value.

The booster-exciter voltage, and consequently the booster voltage, will vary in accordance with the strength and direction of current in the booster-exciter field; and the booster voltage will either buck or boost the excitation voltage and so give double the range of regulation for the same capacity of regulating machine. By means of a Tirrill regulator the alternating-current coil of which is connected to the bus whose voltage is to be regulated, together with suitable resistors and other auxiliary apparatus, the booster-exciter field current is varied in such a manner that the proper boost or buck is applied to the generator field circuit to maintain the desired bus voltage.

When it is desired to change from automatic to non-automatic regulation on a generator equipped with this system, it is essential to close the booster short-circuit breaker before opening the booster circuit breaker to prevent opening the generator field circuit. Below are given the directions for starting a booster, changing from one booster to another, changing regulators and taking a booster out of service, as outlined in the operating code prepared by the Philadelphia Electric Company:

### STARTING A BOOSTER TO OPERATE ALONE

1. Start the booster motor-generator.
2. Start the booster-exciter motor-generator.
3. Close the booster circuit breakers.
4. Open the booster short-circuit circuit breaker.
5. Close the double throw alternating-current potential switch to the bus whose voltage is to be regulated.
6. Select, by means of the direct-current potential plug, the booster which is to supply direct-current potential for the regulators.
7. See that the switch marked "differential relay" is closed.
8. Examine the regulator and see that all the switches connecting the booster exciter field, selected in No. 6, to the regulator are closed.
9. Close selector switch of regulator.
10. Close the field switch of the booster exciter.

### STARTING A BOOSTER AFTER ONE OR MORE ARE IN OPERATION

1. Start the booster motor-generator.
2. Start the booster-exciter motor-generator.
3. Close the booster circuit breakers.
4. Open the booster short-circuit circuit breaker.
5. Examine the regulator and see that the switches connecting the incoming booster to the regulator are closed.
6. Close the field switch of the booster being put into operation.
7. If necessary, make a slight adjustment in the value of the R-3 resistance to permit satisfactory parallel operation.

### CHANGING FROM ONE BOOSTER TO ANOTHER

1. Open the field switches of all booster exciters in service, opening last the switch of the booster to which the direct-current potential plug has been connected.
2. Change the direct-current potential plug to the booster from which it is desired to supply the control potential.
3. Close the field switches of all booster exciters in service, closing first the one to which the direct-current plug is now connected.

### CHANGING REGULATORS

1. See that the differential relay switch of the incoming regulator is closed.
2. Examine the incoming regulator and see that the switches connecting it to the booster-exciter field which is to supply the direct-current potential are closed. (See Rule No. 6, "Starting a Booster to Operate Alone.")
3. Open the field switches of all booster exciters in service, opening last the switch of the booster-exciter field to which the direct-current potential plug has been connected.
4. Change the selector control switch of the regulator in service to the incoming regulator.
5. Close the field switches of all booster exciters in service, closing first the one to which the direct-current potential plug is connected.

### TAKING A BOOSTER OUT OF SERVICE

1. Adjust the generator field rheostats so that the booster voltage is reduced approximately to zero.
2. Open the field switch of the booster exciter.
3. Close the booster short-circuit circuit breaker.
4. Open the booster circuit breakers.
5. Shut down the booster-exciter motor-generator.
6. Shut down the booster motor-generator.

# Redesigning Furnaces for Iowa Coal

OWING to an increased demand for power during the war central stations using high volatile Iowa coal were forced to consider improved methods of increasing their boiler ratings. Since Iowa coal has a volatile content of 36 per cent as against 16 per cent for Virginia coal, it is evident that a furnace designed for Virginia coal cannot successfully burn coal from Iowa. Fortunately a bulletin* had been published which showed that the furnace volume depended upon the excess air, the rate of combustion and the kind of fuel used. It also showed that since the rate of combustion or the number of pounds of fuel per square foot of grate surface per hour increases, the volume of the furnace must be increased proportionately.

The first stoker installation investigated followed generally the stokers designed for Illinois coal, but the ignition rates were low with consequent lower efficiencies. The first arch in the Cedar Rapids plant of the Iowa Railway & Light Company cleared the bridge approximately 24 in. in the center of the furnace and

*Bulletin No. 135 of the Bureau of Mines, entitled "Combustion of Coal and Design of Furnaces," by Henry Kreisinger, C. E. Augustine and F. K. Ovitz.

about 10 in. on the sides. Since the boilers were set approximately 8 ft. from the floor to the lower row of tubes, a limited combustion volume resulted. The only virtue of the peculiar installation of flat arches parallel to the grate was that it was cheaper to construct than the older sprung arch and that the maintenance was also lowered.

As a result of these combustion-area investigations the arches at the rear end of the stoker were raised slightly. This immediately resulted in increased boiler ratings and improved evaporation rates. Then, as these arches wore out in service, the angle between the arch and the grate was increased step by step until finally the rear row of arch tiles was tangent to the bottom of the boiler header. Since it was not possible from an economic standpoint to tear down the boilers and raise them up, other means had to be devised to increase the furnace volume. A modified form of bridge wall was designed to deflect the heat from its surface forward to the feed grate of the stoker.

The next step was to build an "L"-shaped arch, the long portion of the "L" being parallel to the grate and as high up from the grate as the physical dimensions of the boiler would permit. The vertical portion of the "L" was extended downward until it cleared the grate by approximately 18 in. It was made only long enough horizontally to meet the feed grate in order to secure sufficient surface of highly heated firebrick to assist in the ignition of the coal.

Before this arch development occurred evaporation rates of 5 lb. of water per pound of coal and boiler ratings not exceeding 110 to 125 per cent of nominal capacity were prevalent. Today the evaporation has increased to 6 lb. or 7 lb. of water per pound of Iowa coal while the boiler ratings have risen to 200 per cent and 250 per cent of rating.

Along with these changes the gas velocities have been lowered, thereby reducing the amount of ash carried in suspension from the fuel bed and with a corresponding reduction of trouble from slag formation on the tubes. The larger furnace volume with lower gas velocities gives less blowpipe effect on the boiler tubes, with a resulting reduction in the boiler tube maintenance.

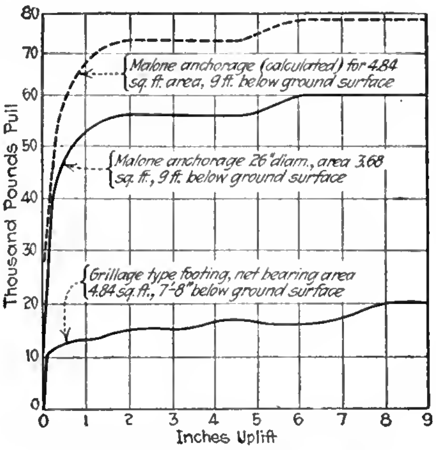
Cedar Rapids, Iowa.

## Anchorage for Overhead Line Structures

A METHOD has been developed in connection with a new type of footing for the anchorage of transmission towers and other overhead supports which not only materially increases the security and life of such anchorages over those made of wood or steel buried immediately in the ground without concrete protection,



RESISTANCE TO UPLIFT OF MALONE FOOTING COMPARED WITH ORDINARY GRILLAGE

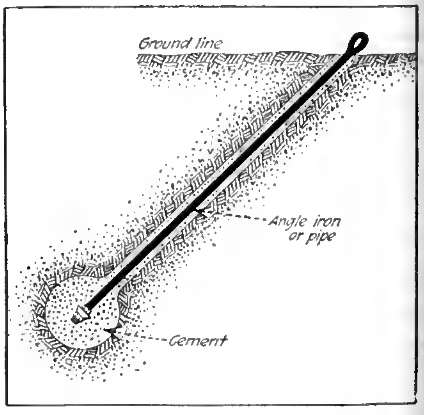
but also largely reduces the construction expense. This new anchorage, although a rather radical departure from past practice, has been sufficiently tested, both as to method and type, to assure its success, at least under the earth conditions that are usually encountered.

In May of last year the writer was assigned to take charge of the construction of a heavy steel-tower transmission line, 110 miles long, to connect two sections of the transmission network of the Kansas Gas & Electric Company in central and southeastern Kansas. Soil explorations were immediately started to determine the conditions to be met in designing tower anchorages. This survey developed the fact that over about 80 per cent of the entire ground to be traversed by the line there would be encountered formations of flint bearing limestone of sufficient hardness to make excavations for earth grillages difficult and expensive, but, on the other hand, of such an erratic and faulty nature as not to be reliable for the grouting of anchor bolts into drilled holes. With the aim of making an asset of this liability, efforts were directed to the development of an efficient tower anchorage which would successfully meet all of these rather unusual conditions and at the same time be adapted to any other conditions likely to be encountered, such as dirt, rock, boulders or combinations of these materials, and capable of being cheaply and quickly installed even in frozen ground.

A series of experiments developed the method and type of anchorage called the Malone anchorage. The installation of this anchorage is simple, the first operation consisting of boring a relatively small hole, or drilling this hole if in rock, and discharging within the hole at the desired depth below the ground surface a selected quantity of explosive. This expands a cavity in the dirt or rock of a size dependent upon the quantity of explosive and density of the material. An experimental hole, permitting inspection, is shown in one of the accompanying illustrations.

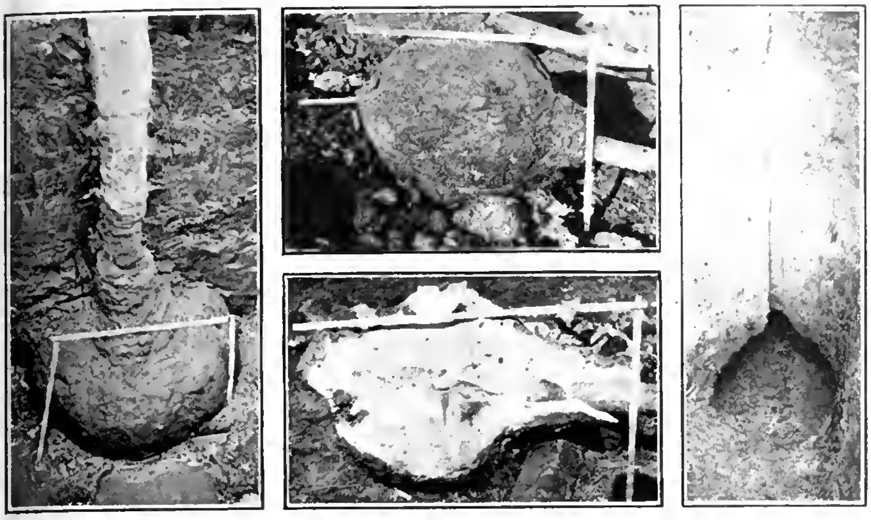
A specially designed column or tension member (frequently formed from angle iron or pipe) is inserted in the hole in correct position, with concrete poured or forced around it in the hole up to the ground surface or to any other desired height. When the concrete is sufficiently set up, the anchorage is ready for the attachment of the structures.

Some of the novel characteristics of the Malone anchorage result from the fact that the force from the explosion subjects the walls of the cavity to a high pressure which compresses the soil immediately adjacent, thereby greatly increasing its strength and resistance.



CONCRETE ANCHORAGE USES VARIOUS STEEL FORMS FOR CENTER

Beginning in June, a series of uplift and compression tests were conducted upon about fifty experimental anchorages. These experiments were sufficiently diversified to establish for the entire range of ground conditions encountered along the transmission line the sizes and types of anchorages required to carry the



VIEWS OF MALONE CONCRETE ANCHORAGE AS IT APPEARS IN PLACE, BROKEN OPEN AND HOLE WITH BULB WITHDRAWN

requisite loads both in tension and in compression. Analysis of the results of these tests brought out many features pertinent to this method of anchorage of which advantage is taken in its application. Among these, as applied to steel transmission towers, the following are of particular interest:

1. Extensive economies resulting from lower cost of material, lower cost of hauling and assembly, reduction in labor requirements, reduction of time element with attendant savings, and lessening of damage to crops and of injury to or loss of live stock sometimes caused by animals falling into open holes excavated for grillage footings.
2. The safe bearing value with this anchorage in compressed soil is well in excess of the accepted practice with undisturbed soil.
3. The rigidity of the column member is materially in excess of that which would be expected from the application of formulas developed for unsupported columns.
4. The earth being highly compressed during the process allows the application of a large percentage of its ultimate load before any movement of the anchorage occurs.
5. Essentially the same values are obtained for uplift and for compression, showing that the effective resistance to uplift is determined by the penetration of the "bulb" through the compressed earth rather than by lifting the conventional "cone of earth."

The accompanying curves show the results of comparative uplift tests upon a Malone anchorage with "bulb" 26 in. in diameter and a steel grillage tower footing of the usual type having an area more than 30 per cent greater. There is also shown a calculated curve corrected to the basis of equal areas. This test was made in clay ground that is normally firm, but saturated, and the grillage footing curve brings out the reduced holding power and tendency to flow of this class of ground when disturbed and tamped.

To give a comparative idea of the material and labor required for the Malone anchorage versus the usual grillage tower footing set in dirt, figures are given in table above.

| | Malone Anchorage | Grillage Footing |
|---|---|---|
| Quantity of earth excavated, cu.yd. | 0.04* | 4 |
| Quantity of steel, lb. | 60 | 220 |
| Quantity of concrete, cu.yd. | 0.25 | 0 |

*Hole 5 in. in diameter and 8 ft. deep.

While a comparison on the basis of actual cost is not available, it is estimated that on standard towers the saving will run from one-third to one-half the cost of the grillage footing as installed by the open excavation method.

Applications of this anchorage are already being made in permanent construction as footings for steel transmission towers and guy anchors for wooden poles and other flexible supports used in transmission work.

Construction Manager.
Phoenix Utility Company,
New York, N. Y.

## Cable Test Equipment Placed on Motor Trailer

HIGH-VOLTAGE dielectric tests on cables and insulators are made in the field by the Edison Electric Illuminating Company of Boston with the equipment shown in the accompanying illustration. The motor truck at the left carries an induction motor which can be operated at 2,300 volts or 4,000 volts, driving a 100-kva., single-phase generator with a voltage range of zero to 2,300, besides the necessary control-panel installation. It is connected by cable with the trailer truck, which carries an 800-kva. transformer and an 800-kva. reactor in parallel with the low-tension side of the former. The transformer secondary range is zero to 30,000 volts. By this equipment the capacity load of the cable under test can be balanced, with corresponding reduction in generating requirements. Four to six men including chauffeur are required on tests.

## Inspections for Better Service

### At Small Cost, Service Has Been Improved by Adjustment of Minor Causes for Complaints, Repairs to Appliances and Suggestions for More Economical Operation

WITH a large system extending over a wide area, such as that of the Consumers' Power Company in Michigan, service to the residential customer frequently does not receive the same attention as that of the commercial or industrial customer because the operation of household equipment is not of a complicated nature. Quite often, though, because of some local condition, the service may not be entirely satisfactory to the customer, or some of his appliances may be out of repair, and yet he will neglect to call upon the company to remedy the trouble. Such conditions mean decreased revenue for the company and sometimes result in misunderstandings and loss of the customer's good will.

With this in mind the Consumers' Power Company has inaugurated a plan of house-to-house inspection to uncover dissatisfaction on the part of the customer, make repairs and adjustments to household appliances and suggest ways of improving the use of the service. The method of conducting the inspection is interesting, and its results are particularly significant as they typify conditions which may exist among the customers of any central-station company. The Consumers' company operates both electric and gas utilities, and the reports of the inspection of gas installations are also included because of their value to combination companies.

Preliminary to making the house-to-house canvass of customers the inspectors were first thoroughly schooled in the various departments, such as meter trouble, appliance repairs and billing, in order that they might be familiar with various conditions which arise and be capable of making repairs or adjustments or answering questions or complaints. As the term implies, an inspection was made of every house adjacent to the gas or electric distribution system. The primary function of the inspection was to render a service to the customer and not to sell appliances or equipment, and the inspectors were instructed that they should not attempt to sell anything even if it was specifically asked for by the customer. In the latter case a salesman is notified of the "prospect."

The inspector presents to the customer a card of introduction with his personal signature. This card explains fully his mission and introduces him as a representative of the company. While this may seem to be a formality, it was greatly appreciated by the customers in that it was a means of identification and they had the name of the inspector if they desired to ask for additional information.

In order to simplify the work of the inspector, cards were prepared which listed the chief appliances to be inspected, repaired or adjusted if necessary, and a record was made of the conditions found. The electrical inspection card is shown here.

Upon entering the house, after presenting his card of introduction, the inspector records accurately the name and address of the customer, noting the general type and use of the building. The service is inspected, low-hanging wires, loose brackets and number of customers supplied being noted, and anything needing repair is reported immediately to the service department. The standard safety cabinet, if any, and the meter are then inspected, with particular attention to the safeness of the installation, open wiring or anything that might prove to be a hazard. The meter number and index readings are recorded.

Fuses are removed and inspected to make sure that the customer is properly protected. Many cases have been found in which coins, nails and heavy wire have been used for fuses. Customers' comments are also reported, whether favorable or unfavorable. These comments, if they are unfavorable, and any direct complaints are either investigated and the trouble corrected at the time by the inspector or are referred to one of the departments, which issues an order for the necessary work to be done. An inspection is also made of all appliances, and minor repairs, such as to broken cords, sockets and loose conections, are made where nec-

FORM OF CARD USED FOR ELECTRIC INSPECTION

essary. In the event that the appliance must be taken to the shop the nature of the trouble is explained and the approximate cost given. Then with the customer's consent the repairs are made.

Each day the inspection cards are turned over to the district manager, and he or some one delegated by him checks them over carefully, noting condition of meters and services and seeing that all major repairs necessary are made. The chief clerk next checks the cards with the ledgers, noting whether the name, address, meter number, meter reading and other ledger records are correct. The cards are then filed in permanent card files for future reference, particularly by the commercial department in laying out sales plans and building up "prospect" lists for new business.

It has been found that the inspection is rendering a great service to many of the customers, in that low-voltage conditions have been improved, service wires repaired, dangerous meter conditions corrected, gas and electric appliances repaired and adjusted, fuses of proper capacity installed and complaints of various conditions answered.

Out of the 35,230 inspections made, there were 13,590 individual repairs or adjustments made or complaints answered. Many of these were of minor importance. However, it is evident that the results being obtained fully warrant the expenditure and that from 20 to 25 per cent of the customers are receiving a service which is a direct benefit to them in the use of gas and electricity.

The accompanying summary shows in detail the result of the inspection as of Dec. 1, 1922.

SUMMARY OF HOUSE-TO-HOUSE INSPECTION

Total number of inspections made 35,230

| | Combination Properties | Straight Electric Properties |
|---|---|---|
| Number of inspections made | 18,835 | 16,395 |
| Number of inspectors working | 15 | 7 |

**Inspector's Introduction Card**

TO OUR CUSTOMERS:

The bearer will present to you credentials showing his name, company badge and his photograph, identifying him as a representative of this company.

With your permission, he will examine your gas and electric appliances and make, without charge, the minor repairs and adjustments that may be necessary to make their use more satisfactory to you.

His call is solely in the interest of better service. He is not a salesman and has nothing to sell.

If you will give him the opportunity, we feel sure the adjustments he will make and the advice he will give you will be helpful to you.

CONSUMERS' POWER COMPANY.

Presented by ..................

## Cost of Electric Pumping in Oil Fields

COMPARATIVE data prepared by the San Joaquin Light & Power Corporation on the use of electricity in the oil fields of Kern County, California, show that the cost of electric pumping is much less than by any other method. With 3,000 wells being pumped electrically from the lines of this one power company, the figures cover a wide range of possible variation in conditions and represent a true comparison of electric, gas and steam engine drive.

The lump operating costs without details for individual oil-well installations for one division of a large oil-producing company are per day per well as follows: Electric drive, $1; gas-engine drive, $2.16; steam-engine drive, $5. These figures are based on the installation of individual electric motors or gas engines at each well, or the installation of one steam boiler serving fifteen individual steam engines, each driving one well.

The motors used in oil-well operation are two-speed, rated at 15 hp. or 30 hp., the lower rating being used for pumping and the higher rating for pulling, casing and drilling. The average load when pumping in one particular district is about 6 hp. At present prices of oil, the operating cost of steam installations is the same whether oil or natural gas is burned under the boiler.

## Cleveland, 1922, Appliance Sales Were $15 per Customer

CONCRETE evidence of the value of co-operation between the central station and the contractor-dealer in building up a large volume of appliance business is revealed in a survey recently made in Cleveland. While the Cleveland Electric Illuminating Company does not engage directly in merchandising, it gives its whole-hearted support to all of the activities of the city's electrical interests. As has been noted from time to time in the ELECTRICAL WORLD, the company has participated in electrical home exhibits and has joined with the dealers and electric shops in formulating and carrying out sales programs. How well this has worked out is shown in the accompanying tabulation of information concerning eighty-five electric shops in Cleveland.

Analyzing these figures briefly, G. E. Miller, sales manager of the Cleveland Electric Illuminating Company, says:

"The data given cover only so-called electrical shops—that is, contractor-dealer stores—and do not include or make any allowance for sales made by our large stores, hardware stores, drug stores or automobile supply houses, all of which sell more or less electrical merchandise; in fact, the large stores are selling large quantities. I have just had a report of one of the stores which, in a special sale, sold 243 washing machines in one day and on another day sold fifty-nine mangles. Another large store had special sales on washing machines running as high as from fifty to sixty washing machines per day.

"I have made the statement, which I believe is very conservative, to the effect that the sale of domestic appliances in Cleveland in 1922 was in excess of $3,000,000, not including in that figure lamps, electric fixtures, wiring material, sockets and so forth. That is approximately $15 per residence consumer in the territory and approximately $3.40 per capita.

DATA ON APPLIANCE SALES IN CLEVELAND ELECTRIC SHOPS*

| | |
|---|---|
| Number of appliance dealers | 85 |
| Total space devoted to display of electrical merchandise, sq.ft. | 53,095 |
| Number of display windows | 145 |
| Frontage of all dealers' windows, ft. | 1,592 |
| Number of salesmen—in stores | 145 |
| Number of outside appliance salesmen | 254 |
| Total number of appliance salesmen | 399 |
| Average number of appliances sold each month | 7,039 |
| Total for one year | 84,468 |
| Value of appliances sold in 1922 | $2,765,406.00 |

*Not including department-store sales or sales made by other than electrical stores.

"You will note that the total number of appliance salesmen is given as 399, in addition to which it is safe to assume that there are probably fifty more, or say a total of 450 men, whose entire time is devoted to the retail sale of electrical equipment in Cleveland and its suburbs. To get another picture of what this sales effort means—if we were to assume that these men were working at the ridiculously low figure of $125 per month, this represents a payroll of $675,000 per year. Obviously, they would have to sell much more than $3,000,000 worth of merchandise to warrant any such outlay for sales effort."

## Operating Costs of Municipal and Private Plants

ANALYSIS of the operating costs of privately owned and municipal utilities in Indiana, compiled from annual reports filed with the state Public Service Commission, show that the operating costs of the municipal utilities is far greater than that of the other class, according to a statement made at the commission offices.

In the statistics compiled private and municipal electric utilities are compared. The disposition of each $100 of revenue is shown. The municipal utilities pay much more for coal than the private concerns. More also is paid for wages and salaries

| | Private | Municipally Owned |
|---|---|---|
| Salaries | $3.41 | $3.68 |
| Wages | 14.35 | 18.58 |
| Material used on repairs | 3.82 | 6.09 |
| Fuel, current, steam | 25.94 | 36.24 |
| Other operating expense, including depreciation | 16.41 | 8.85 |
| Total above | $63.93 | $73.44 |
| Taxes | 7.68 | *000 |
| Total operating expense | $71.61 | |
| Balance applicable to interest, dividends, surplus, etc. | 28.39 | 26.56 |
| Total | $100.00 | $100.00 |

*Municipally owned utilities do not pay taxes, these being an added tax burden to the citizens of the city served.

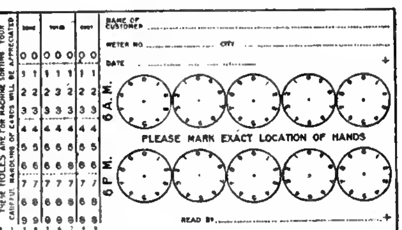
by the municipal utilities, which are to some degree mixed up with politics.

Out of each $100 of revenue received by electric utilities the privately owned company spends $63.93 for operating expenses, whereas the municipally owned utility spends $73.44. The figures are based on the reports for 1921.

The accompanying table shows the difference in costs for various items. It will be noted that very little has been set aside by the municipal plants for depreciation.

## A Check on Registration of Power Meters

ON AN extensive system like the Southern Power Company's, which serves industrial loads, it is very important that some check be kept on the registration of meters between the regular monthly calls of the meter readers, otherwise the failure of a meter to record may entail serious loss to the company. Furthermore, since the company sells



POST CARD USED FOR RECORDING METER INDEX

both primary and secondary power (primary power being power for twelve months of the year and secondary power that which may be provided for less than twelve months upon proper notice), it is desirable to ascertain whether a consumer is complying with his contract. Consequently the Southern Power Company has required (by contract) all its industrial consumers to mail their meter readings regularly on a post card like that reproduced herewith. When these are received they are punched on a Hollerith machine according to zone, substation and consumer number for automatic sorting. After being sorted the readings are transferred to permanent records for the purposes formerly mentioned.

While these cards may not be used in exactly the same way by all companies, it is possible that they can be used by companies serving sparsely settled teritories to reduce the cost of meter reading. With these readings received monthly it might be necessary only to send a meter reader around every three months to consumers whose bills are comparatively small. It is possible too that the punching system might be arranged to permit using the cards for directly billing the customers; that is, for stamping the amount due on the customer's bill.

## What Other Companies Are Doing

**Oklahoma City, Okla.**—To facilitate the supervision of its properties west of Oklahoma City, a western division of the Oklahoma Gas & Electric Company was established on Jan. 1, to take in all the properties in the Enid and El Reno divisions. The Oklahoma City division will comprise the properties in Oklahoma City, Moore, Norman, Britton, Bethany and Yukon.

**Boston, Mass.**—Utilities operated by Charles H. Tenney & Company sold electrical appliances in 1922 to the amount of about $420,000, the total gas and electric appliance sales being approximately $700,000. As a slogan for 1923 on total appliance sales, these companies have adopted the phrase "A Million or More—Before '24." Cyrus Barnes is general sales manager.

**Louisville, Ky.**—The Kentucky Utilities Company's lighting-fixture sales during the year 1922 amounted to $30,191.77. The fixtures were sold under a consignment arrangement for twenty-two of the company's offices. This business was done with a stock of $6,000 in fixture samples. Selling assistance was also furnished by the fixture jobber.

**Chicago, Ill.**—Plans for a series of active campaigns dealing with electric appliances in familiar use are being perfected by the retail merchandise sales department of the Public Service Company of Northern Illinois. It is intended to continue the policy of arranging in advance every detail of the advertising and publicity which will characterize the sales, extending this to the point of arranging in each salesroom a prominent display of the article or articles involved. The idea which was followed out last year aided materially in obtaining results in 1922, which showed an increase of 66 per cent over the sales of the year previous. The advantage of pushing appliances most in use at the particular season has been demonstrated and the lesson learned will be heeded.

# Digest of Electrical Literature

Including Brief Abstracts of and References to Important Articles Appearing in the Scientific and Engineering Press from All Parts of the World

## Hydro-Electric Development and Steam Equipment

*Siphon to Maintain Constant Water Level.* — F. HEYN. — The author describes a siphon which automatically takes care of the maintenance of a steady and predetermined water level in a dammed river. Because of the peculiar shape of the cross-section of this siphon it fills itself with water and starts to operate without any attendance. It would appear that such an apparatus could be used only on very small water plants, but the author states that one of these siphons will be installed at a new Bavarian hydro-electric station capable of passing 110 cu.m. of water per second.—*Elektrische Kraftbetriebe und Bahnen,* Dec. 24, 1922.

*Development of Stokers.*—The January issue of the *A. S. M. E. Journal* contains three papers dealing with the various types of stokers that have been developed for the firing of boiler furnaces and that were presented at the annual meeting of the society. They are "The Development and Use of the Modern Chain Grate," by T. A. Marsh; "Overfeed Stokers of the Inclined Type," by G. I. Bouton, and "The Design and Operation of Underfeed Stokers," by H. F. Lawrence. A fourth paper, "Tests of a Large Type W Stirling Boiler," by P. W. Thompson, is also included. Abstracts of these four papers may be found in the convention report published in the ELECTRICAL WORLD for Dec. 9, on page 1288. —*Mechanical Engineering,* January, 1923.

*Electric Drive for Turbine Auxiliaries.*—J. M. DRABELLE.—The author gives the rating of the electrically driven turbine auxiliaries in the Iowa Railway & Light Company's power station, describing their automatic features and giving operating data from the results obtained. He strongly advocates driving power-house auxiliaries with electric motors in preference to any other method.—*General Electric Review,* January, 1922.

## Generation, Control and Switching

*Paralleling Troubles.*—J. GEIGER.—The author reports two rather unusual experiences with the parallel operation of alternators. In one case where a steam turbine-generator was operating in parallel with a belt-driven generator the pointers of the ammeter and wattmeter of the latter were swinging periodically between normal values and twice normal values, and this was found to be caused by a resonance phenomenon of the instrument systems with the periodic knock of the belt lock upon the generator pulley. In the second case a Diesel motor power plant, with units of 100 kw. to 1,000 kw., operated in parallel with a 1,000-kw. steam turbo-generator. The instruments of the Diesel plant indicated periodically very heavy overloads, while the meters of the steam plant were quiet. The cause was found in the totally different character of the speed regulators used in the two plants. The regulator of the turbine was rather sluggish, while the oil motors had very sensitive regulators. In case a slight increase of load came on, the combustion motors responded much more quickly than the steam turbine and carried therefore temporarily a much higher load. An addition of oil dash pots to the regulators of the Diesel motors brought complete remedy for this trouble.—*Elektrotechnische Zeitschrift,* Jan. 4, 1923.

## Transmission, Substations and Distribution

*New Disk-Type Insulator.*—A. VAUPEL.—A cap-type chain insulator is described, very similar in outer shape to the recently developed "sphere-head" insulator. But the fastening of the rod within the head of the insulator is accomplished by means of a number of peculiarly arranged small iron pieces, assembled obliquely and concentrically around the rod. No cement is used. Comparative data for four types of insulator are given in the table. —*Elektrotechnische Zeitschrift,* Jan. 18, 1923.

| | Hewlett | Cemented-Cap Type | Sphere-Head Type | New Type |
|---|---|---|---|---|
| Puncture under oil, in kv.. | 100 | 130 | 160 | 180 |
| Mechanical strength, in kg. per sq.cm....... | 3,500 | 3,500 | 5,000 | 5,830 |

*Cement Bases for Wooden Poles.*—T. PANSERT.—This paper describes a method developed by M. Ponsolle of providing cement bases for wooden poles. The base consists of a cylindrical cement tube, conical on the inside and about 3 m. in height. The pole rests with its tapered end within the conical part of the tube, and its outside diameter is somewhat smaller than the inside diameter of the base tube, so that there is free access of air and ready drainage of water, both tending to prevent premature decaying of the pole butt. Wedge-shaped spacers hold the pole concentrically. A similar but two-part cement tube is described, to be used on poles already set. The method has been tested since 1908 and has been found to be both cheap and effective.—*Revue Générale de l'Electricité,* Jan. 20, 1923.

*Static Condensers for Power-Factor Correction.*—R. E. MARBURY.—Correction of power factor with static condensers, fundamentals of condenser design, factors of safety adopted and the application of static condensers to power lines are the main subjects discussed.—*Electric Journal,* February, 1923.

## Units, Measurements and Instruments

*Simplified High-Potential Test of Insulating Materials.*—G. J. MEYER.—To permit quick routine testing of pieces of insulating material a small handle with two point contacts spaced 5 mm. apart is described. The points are connected to a source of 3,500 volts to 4,000 volts, and are placed upon different parts of the piece under test. Perfect material will stand the test without any sparking or burning, while defective or moist pieces will cause a surface arc between the points. It is explained how the character of the burn gives a clue as to the nature of the defect in the material. The method has been used successfully for several years by the Dr. Paul Meyer Company in testing insulating materials intended for use on 500-volt work.—*Elektrotechnische Zeitschrift,* Jan. 4, 1923.

## Motors and Control

*Small-Capacity Synchronous Motor.* —L. SCHÜLER.—A series of small self-excited synchronous motors, in capacities from 3 kw. to 22 kw., is described. The motors have a wound armature, to which is connected a commutator for the direct current excitation and three collector rings. The armature receives the line current through the slip rings, while the stator is connected to the starter. The commutation is claimed to be sparkless even at high overload start or run. The motor starts under full load as an asynchronous motor, synchronizes quickly, and runs then as a synchronous motor with all the advantages of that type. At a load exceeding the normal rating the rotor falls out of step and runs as an induction motor until the load decreases, when it assumes synchronous speed again. This change is not noticed save for a drop of the power factor from unity to about 80 per cent. The advantages claimed are that the efficiency is slightly above that of an equivalent induction motor, the current consumption is about 15 per cent less, the iron losses are lower and the cost is about 20 per cent to 25 per cent higher. The latter item is partly compensated by the higher output which the motor gives when running as a synchronous unit.—*Elektrotechnische Zeitschrift,* Jan. 4, 1923.

*Maintaining Electric Railway Motors.* —J. S. DEAN.—Particular care should be used when replacing field coils in motors to insure that they are connected properly and that the correct

polarity is obtained. Various methods for testing are given.—*Electric Railway Journal*, Jan. 20, 1923.

### Illumination

*Use of Artificial Illuminants in Kinema Studios.*—L. A. JONES.—The subject is treated under the following two divisions: (a) the study of the characteristics of photographic materials and their response to different forms of radiation, and (b) the effect of light and radiation on the human eye. The first part is given over to a definition of photographic terms and units and an estimation of the effect of various illuminants in photographic work. The second part is devoted to the possibilities of injury to the eye of workers in kinema studios through radiation of harmful qualities or excessive intensity.—*Illuminating Engineer*, Vol. 15, Nos. 9 and 10.

*Specifications Governing the Acceptability of Electric Tail Lamps for Motor Vehicles.* — Specifications have been drawn up by the committee on motor-vehicle lighting of the I. E. S. and the lighting division of the standards committee of the Society of Automotive Engineers. They have been drawn to apply only to illumination by electric lamps of opaque registration number plates for use on automobiles, trucks, and motor cycles.—*Transactions of the I. E. S.*, February, 1923.

### Heat Applications and Material Handling

*Electric Heating of Rivets and Forgings.*—J. SAUER.—This paper describes the latest types of stationary and portable rivet heaters, with interesting curves on the efficiency, the power factor and the energy consumption of the apparatus. To estimate the energy required to heat a certain piece of steel, the author gives the formula $Q = 0.11 \times G \times t$, wherein $Q$ denotes heat energy in kilogram-calories (1 kw.-hr. = 864 kg.-cal.), $G$ is the weight of the piece in kilograms, $t$ is the desired temperature, and 0.11 is the specific heat of steel at 1,000 deg. C.—*A. E. G. Mitteilungen*, December, 1922.

*Arc Welding.*—O. H. ESCHHOLZ.—The author reviews the recent progress of arc-welding activities. Fusion welds, mechanical working, arc phenomena, penetration and high-speed welding are considered. Tables included give the rate of metal deposition, maximum welding speed for ½-in. plate using butt joints, and maximum welding speed for ½-in. plate using lap joints.—*Journal of American Welding Society*, January, 1923.

### Electrophysics, Electrochemistry and Batteries

*Durable Insulating Oils.*—C. J. RODMAN.—In searching the entire field of inorganic and organic liquids only a few liquid dielectrics were found to be adapted to insulation purposes, such as the use of oil in transformers, switches, lightning arresters, etc. Those compounds most nearly meeting the requirements are a small number of mineral oils, known as paraffine and naphthene hydrocarbons. The best commercial oils are derived from petroleum crudes and have very good physico-chemical characteristics.—*Electric Journal*, February, 1923.

*Apparatus for Determination of Magnetic Properties of Short Bars.*—M. F. FISCHER.—A description is given of the apparatus and methods developed for the magnetic testing of single specimens 10 cm. long and 0.6 cm. in diameter. As the magnetic properties of small samples are difficult to measure directly, a method has been adopted which involves the comparison of the test bar whose properties have been previously determined by calibration with several standard bars. The accuracy attainable with this method is entirely satisfactory, the errors in most cases being less than 5 per cent.—*Scientific Paper, No. 458 of the Bureau of Standards.*

### Traction

*Reducing Lubrication Costs.*—H. M. ROBINSON.—Methods of lubrication and amount of lubricant used on various types of motor and journal bearings on the rolling stock of the Northern Texas Traction Company and Tarrant County Traction Company, Fort Worth, Tex., are recounted. Cost of rolling-stock lubrication per thousand car-miles, amount of oil needed for car and regular inspection, oiling schedule for cars, etc., are given in tabular and curve form.—*Electric Railway Journal*, Jan. 20, 1923.

*Electric Railways Crossing Swinging Bridges.* — G. VALLECCHI. — When an electric railway crosses a swinging bridge the continuity of the line must be assured at all times. This article explains how the author solved this problem recently in Taranto, Italy, by feeding the contact wire and rails exactly to the two shafts where the two parts of the bridge swing. These two points are permanently connected together and in contact with the two branches of the railroad on either side of the river by means of cables. Swinging contacts, flexible or shiftable, are absolutely avoided, and no special assistance is required.—*Elettrotecnica*, Nov. 15, 1922.

### Telegraphy, Telephony, Radio and Signals

*Alternating-Current Telegraphy* with *Acoustical Frequency.*—F. LÜSCHEN.—The unreliable operation of single-wire telegraph lines and the inductive interference caused by high-voltage lines, and specially railway feeders, made it necessary to rebuild the telegraph lines for double-wire cable, as has been done with telephone lines. The considerably increased cost of such double lines was counteracted by their multiple use. A new system of multiple telegraphy with alternating currents of different frequency is described. This system permits "Pupinized" lines, such as are used for telephone service, to carry simultaneously six telegraphic messages with six different frequencies between 400 cycles and 1,700 cycles per second. Specially adapted electron tubes act as oscillators, amplifiers and rectifiers at voltages equal to those customary in telephony. The Siemens rapid machine telegraph, with perforated paper ribbon, gives a speed of six hundred to seven hundred letters per minute for each of the six messages. At the receiving end the usual band filters, each tuned for its particular frequency, separate the six codes again. The author enlarges upon the many difficulties which had to be overcome to make this system operate reliably. It is installed on the cable between Berlin and the Rhineland.—*Elektrotechnische Zeitschrift*, Jan. 4 and 11, 1923.

### Miscellaneous

*Developments in the Electrical Industry During* 1922.—JOHN LISTON.—Although progress in the electrical industry was mainly along established lines, there was a well-defined tendency in practically every phase of construction of electrical apparatus to concentrate the generation, transformation and distribution of electrical energy in units of greater capacities and with higher guaranteed efficiencies than in previous years. This is illustrated in one instance by the increase in transformer sizes, as shown in the accompanying table.

AVERAGE UNIT SIZE OF POWER TRANSFORMERS IN KVA.

| Year | Self-Cooled | Water-Cooled | All Types |
|---|---|---|---|
| 1919 | 1,175 | 4,325 | 2,150 |
| 1920 | 1,325 | 3,175 | 2,175 |
| 1921 | 1,575 | 4,150 | 2,750 |
| 1922 | 1,700 | 6,000 | 3,750 |

The maximum rating for steam-turbine generator sets was advanced to 62,500 kva. and that for waterwheel generators to 65,000 kva. The first electrically propelled ferryboat was placed in service last summer. Automatic station practice made further technical and commercial gains, with a steady increase in the unit capacities of the equipments and improvements in the design of the small-sized but very important devices which make automatic operation not only feasible, but fully as reliable as hand operation. Among other items of interest in widely varying fields were a new type of induction furnace for melting non-ferrous metals, the production of a highly efficient steam generator for use where surplus electrical energy is available, the "pallophotophone" for recording and reproducing sound, the 30-kw. incandescent lamp, radio and power tubes of unprecedented capacity, and further development of the million-volt testing set for commercial and research work. The review is forty-five pages long, amply illustrated. — *General Electric Review*, January, 1923.

Chronicle of Important Events and General Activities, Announcements and Reports of Association Meetings, Court Decisions and Commission Rulings and News of Electrical Men

## Lieb on Coal Situation

**How the Threatened Harm to Utility Operation from Fuel Scarcity May Be Combated**

SPEAKING before the regular monthly luncheon of the New York Electrical League on Wednesday of this week, John W. Lieb, vice-president New York Edison Company and chairman of the joint fuel committee representing the national electric light and power, electric railway and gas associations, which has been an active factor in obtaining fair treatment for the utilities during and since the coal strike, gave a comprehensive résumé of the whole fuel situation as it affects the utilities and especially the central-station companies dependent on steam operation. After sketching the importance of these utilities in the life of the nation, Mr. Lieb dwelt on the imperative necessity of their obtaining an adequate supply of good coal if their service to the public is to be maintained. Such a supply, he pointed out, has been placed in jeopardy by the changes recent years have brought in the coal-mining industry. From 1910 to 1920 there was an increase of 154 per cent in the number of mines, with only 37 per cent increase in output. As a result, in 1921 the average number of days in which individual miners worked was only 149. This whole condition not only increased overhead and hindered efficient collection and distribution of coal by the railroads but led directly to the strike. The strike was speedily complicated by the troubles with the railroad shopmen. The ultimate result to the utilities has been scarcity of fuel supply, enormous increase in cost and deterioration of quality, with attendant injury to furnaces, lessening of efficiency and forced reduction of storage. With 20 to 40 per cent of the total operating cost and 70 to 80 per cent of generating cost due to coal, the steam-electric utilities were harder hit by the situation than any other industry. Their coal contracts have proved of little value during emergencies unless they are protected by priority orders.

### What Are the Remedies?

Mr. Lieb then turned to the remedies for the grave ills to which the fuel situation has given rise. He advocated more extensive storage by the railroads and at the mines themselves, which would permit the miners to work with greater steadiness. The more general use of electric machinery by mines would also be of much benefit; at present only half of them use electric coal-cutting machinery and the total mine power supplied by central stations is only 880,000 hp. The value of generating stations at the mouth of the mine when sufficient water can be had, the feasibility of pumping coal to market and the advantage that would follow the construction of superpower transmission lines were dwelt upon in turn, and the high economy of great central stations like the one at Hell Gate, which produces a kilowatt-hour on 1.35 lb. of coal, was alluded to.

Expressing his determined opposition to government ownership and operation of mines, Mr. Lieb declared himself in favor of continued private ownership with government regulation such as utilities are subject to.

Mr. Lieb spoke to a large gathering, including many prominent executive officers of public utilities.

## Fight to Abolish the Utah Commission Fails

A determined fight made by stageline companies and other opponents of the Utah Public Utilities Commission to bring about its abolition was frustrated this week, when a bill to accomplish that end was killed in the Legislature. A number of other bills concerning the duties and powers of the commission are now before the Legislature.

## Rumored Merger of McKinley and Studebaker Interests

Persistent and apparently well-founded rumors in the financial district of New York point to a change in the control of the Illinois Traction Company and its consolidation with the so-called Studebaker group of utilities into a two-hundred-million-dollar company. The Illinois Traction Company, of which Senator William B. McKinley is president and H. E. Chubbuck vice-president executive, is one of the largest holding companies in the United States, operating—besides 600 miles of electric railway—light and power companies and gas plants in cities of Illinois, Iowa and Kansas. The Studebaker properties are embraced in the system of the North American Light & Power Company, of which Clement Studebaker, Jr., of South Bend, Ind., is chairman of the board and William A. Baehr of Chicago president and general manager. The company, incorporated in Maine in 1915, owns and controls subsidiary operating companies in the light and power field serving a population of more than 300,000 in 104 communities in Missouri, Ohio, Illinois and Oklahoma.

## Culminating New York Bill

**New Administration Measure Meant to Insure City Control of Utilities Within Boundaries**

AN ADMINISTRATION bill embodying sweeping "home rule" provisions for the regulat..n of public utilities and held to be even more significant than the measures described in the ELECTRICAL WORLD last week (page 467) was introduced in the New York State Legislature on Tuesday of this week. This measure has been drawn in accordance with recommendations contained in the Governor's first message and confers almost mandatory jurisdiction upon all cities of the state to regulate their own public utilities—mandatory in the sense that every city will assume such jurisdiction unless by a resolution of its governing board approved by the Mayor it shall elect to have the public utilities within its border regulated by the Public Service Commission of the state. The newly created bodies are to be called "city public utilities commissions." Their term of office and compensation are left to the judgment of the governing board of each city, which may, if it see fit, require an existing city body or officer to act as such a commission.

### Liberal "Home Rule" Provided

This is the measure giving to upstate cities power to deal with local transit, gas and lighting companies. It applies to all public service utilities in New York City except transit. The bill has twice been withdrawn for amendment, once at the suggestion of corporation counsels from the upstate cities. Now it is said to be in such shape as to be satisfactory to the larger upstate cities, especially Buffalo and Syracuse. Its notable feature is that it allows local regulation of all of that portion of a utility lying wholly within a city, with power reserved to the State Public Service Commission to establish and enforce rates or charges for through services rendered, whether alone or in conjunction with any other corporation, by any utility not wholly within a city; to prescribe a uniform system of accounts, to require the filing of schedules and tariffs, or to approve the issuance of stocks or bonds by all public utilities.

The political possibilities of the application of the proposed law are said to be many, and it is predicted by competent critics that, if the bill becomes law, there will be much conflict of jurisdiction between the state body and the local utility commissions, much that

the companies affected will place their own interpretation on and much that the courts will be called upon to determine. It is even said that, instead of the problem being solved, there is a possibility that in many cities the upshot will be no real regulation at all.

The public service committee of the State Senate will on March 14 hold a hearing on the bills previously introduced for the regulation of public utilities.

# New Central-Station Use for Radio

**Commonwealth Edison Company Broadcasts Its Annual Report—Fifteen Hundred Stockholders at Meeting—Dividends and Surplus for 1922 More than $6,250,000**

WITH an attendance of approximately 1,500 stockholders, overflowing into the corridors, and a radio audience of unknown proportions comprising stockholders, customers and any others who cared to "listen in," the Commonwealth Edison Company destroyed all chances of charges of secrecy at the annual meeting of its stockholders held last Monday afternoon at 5 o'clock. The entire proceedings of the meeting were, in accordance with advertisements in Saturday and Sunday newspapers, broadcasted from the Westinghouse Electric & Manufacturing Company's radiophone station on the Edison Building. It is not yet known over how wide a territory outside the city the proceedings were heard. The matter sent out included the formal proceedings of the meeting and the address of President Samuel Insull. This is believed to be the first instance in which any attempt has been made to broadcast such matter.

President Insull said that there were 600,000 shares of stock entitled to vote at the meeting, of which 451,906, or slightly less than 80 per cent, were represented personally or by proxy. Of these 90 per cent are owned in Chicago and another 5 per cent in Illinois outside of Chicago. Ninety-six per cent of the stockholders own 90 per cent of the outstanding stock. Mr. Insull gave the number of stockholders as 28,489. Of 7,098 employees, 1,129 of whom were added last year, Mr. Insull said that one in three is a stockholder.

The revenue of $43,107,955 for the year 1922 shown in the company's annual report is an increase of nearly $6,000,000 over 1921. Mr. Insull gave the budget for plant expenditures for the coming year as $23,000,000. Approximately $3,500,000 is to be spent on the new Crawford Avenue station now under construction, $7,500,000 in finishing the Calumet station and $500,000 to $600,000 on other stations. It is estimated that the following approximate amounts will be spent on other items: Substations, $3,000,000; conduits, $2,000,000; underground cables, $1,250,000; overhead construction, $3,000,000; meters, $1,300,000 to $1,400,000, and miscellaneous items, $800,000. Mr. Insull estimated that the total expenditure for the coming five years would be in the neighborhood of $100,000,000. He prophesied that the company would have almost 1,000,000 kw. in plant capacity by 1925.

*Attention!*

**Commonwealth Edison Company Stockholders and Customers**

*Radio to Broadcast Stockholders Meeting, 5 P. M., Monday, February 26, 1923*

The annual meeting of the stockholders of the Commonwealth Edison Company will be held at 5 p. m., Monday, February 26th, in Customer's Hall, Edison Building, 72 West Adams Street.

We have today approximately 27,000 stockholders as well as 615,000 customers. Because of the great growth in number of stockholders and the desire of the management that all be as closely informed as possible in regard to the company's affairs, the radio will be utilized to broadcast the proceedings of the annual meeting of stockholders.

This will be good news particularly to those stockholders who will be about their housework at five o'clock or who may be out of the city and unable to attend.

The entire proceedings will be broadcasted from Station KYW of the Westinghouse Electric & Manufacturing Company located on the roof of the Edison Building.

Promptly at 5 P. M., Central Standard Time, the meeting will open. The annual address of Mr. Samuel Insull, President, will directly follow the formal reading of minutes of the previous meeting, the counting of stockholders' votes and disposal of formal motions.

Customers of the Company are also invited to "listen in" as Mr. Insull will undoubtedly have something interesting to say about the future.

This is the first time in the history of any corporation that a meeting of the stockholders has been thrown open to the general public via radio. The Commonwealth Edison Company will be pleased to hear from stockholders, particularly those living at distant points, as to the success of this undertaking.

*Commonwealth Edison Company*

| Dividends paid.......... | | 4,602,416.00 |
| Balance carried to surplus. | | $1,673,958.77 |

### THE ANNUAL REPORT

The electrical operating revenue of the company, the annual report showed, totaled $43,107,955.71, with electric operating expenses (including amortization and depreciation of $3,287,311.67) amounting to $28,418,946.77. The net income available for dividends after all interest items were paid was $6,276,374.77, of which $4,602,416 was paid out for such purposes and $1,673,958.77 carried to surplus. An increase of $1,600,000 in the cost of operation due to the coal strike during the year occurred, but was more than offset by the profit derived from the very large increase in operating revenue. In all 73,321 consumers were added to the company's lines in 1922, making a total at the end of the year of 610,303. The total energy generated in 1922 was 2,225,443,000 kw.-hr., as against 1,928,272,000 kw.-hr. in 1921. The maximum load was 600,000 kw., as against 526,000 kw. in 1921, or an increase of about 14 per cent. The free delivery of lamps, which had been curtailed during the war, was resumed last February.

The issuance of $12,000,000 additional capital stock and the action of the board of directors in recommending the authorization of an increase in capital stock from $80,000,000 to $100,000,000 were reported, and the latter recommendation was acted on formally.

## Prosperous Year for Illinois Public Service

The annual report for the fiscal year ended Dec. 31, 1922, shows that both the operating revenue and the net income of the Public Service Company of Northern Illinois were substantially increased over 1921. With an increase in customers from 118,304 in 1921 to 133,600 in 1922, the gross operating revenues also increased from $12,213,315.93 to $13,712,094.90. Last year's net income available for dividends was $1,835,470.27 against $1,579,535.65 in 1921. The surplus for 1922, after deducting dividends, a depreciation account of $670,660 and other charges, amounted to $446,372.52, as against $275,262.65 in 1921. The company's total operating revenues from gas, electricity, heating and water service showed an increase of $1,498,778.97 over the year 1921. The report contains details of plant extensions, which are to include the new plant at Waukegan and 30,000-kw. additions at the Joliet station and a review of the new substations and transmission lines constructed during the year.

At the stockholders' meeting on Feb. 26 it was voted to increase the capital stock of the company by 50,000 shares of 6 per cent preferred stock, par value $100, and 100,000 additional shares of common stock without par value, to be on a parity in all respects with the present outstanding stock of the company. This will be issued as needed during the coming year.

## Standard Gas & Electric Has Best Year

Figures given out by H. M. Byllesby & Company show that the Standard Gas & Electric Company in the twelve months ended Dec. 31, 1922, had the most successful year in its history. A preliminary earnings statement for the period indicates that the company had a balance of earnings of $1,386,457 after deduction of all expenses, interest charges, taxes, preferred dividends and amortization and other reserves. This is the equivalent of 13.07 per cent on the common stock of the company outstanding. In the previous year the balance for the common shares, after all charges, was $1,080,980, or 10.19 per cent.

## New Trial Ordered

### Litigation Between Southern Power Company and North Carolina Mills Sent Back to County

THE power-rate case in which North Carolina cotton mills are fighting the Southern Power Company, which has attracted great attention in that territory, was last week remanded by the Supreme Court of North Carolina to the Cleveland County (N. C.) court for retrial. This case hinges on the reasonableness of the rates prescribed by the North Carolina Corporation Commission, and the controversy started in November, 1920, when the power company applied to the commission for an increase of rates and abrogation of existing contracts and received permission to charge 1.25 cents a kilowatt-hour for primary power in the amount of 50,000 kw.-hr. a month, with an increasing or diminishing charge for less or greater amounts, and 1 cent for secondary power on the same basis.

A large number of cotton mills accepted the ruling of the commission, but appeals were taken to the county court by twenty-three of them, divided into three groups holding long-time contracts which had been set aside. One of these groups subsequently sought to withdraw from the suit, a mistrial resulted, and the case was brought before the Supreme Court. This body in ordering a retrial declared the appeal to it to be "fragmentary and premature," but went on record to the effect that the rate question involved is intrastate and not interstate, that no discrimination lies in the fact that the Southern Power Company may sell power cheaper in South Carolina than in North Carolina, and that there is no valid objection to the Corporation Commission's basis for rate fixing.

## Ohioans Discuss Lighting Problems

Conservation of school children's eyesight is one of the greatest present-day illuminating engineering problems, according to Prof. H. B. Dates, Case School of Applied Science, Cleveland, who read a paper on public-school lighting before the new-business co-operations committee of the Ohio Electric Light Association at Columbus on Feb. 21. Although the average cost of good school lighting would not run over one-half of 1 per cent of the total school expenses, this expenditure would do much to allay defective vision in pupils, he said. He told of the installation of six units 16 in. in diameter in the 900-sq.ft. schoolrooms in Cleveland, where 150-watt bulbs are used. Professor Dates found this type of equipment to give the best average results with an intensity of 5 to 8 foot-candles.

Prof. F. C. Caldwell, Ohio State University, felt that more attention should be given to the esthetic values of school lighting.

Dr. M. Luckiesh of Cleveland lamented the fact that fixture designers are too ambitious in selling designs rather than the idea of illumination itself. With most of the present-day equipment copied after antique designs, he declared that there was not a single 1923 model which would serve effectively as an illuminating medium.

Progress in rural service was discussed by D. L. Gaskill, Greenville, who saw a growing tendency on the part of the farmer to prefer the minimum charge for service rather than a fixed charge added to the cost of energy at urban rates. This seems to be due to the fact that with the minimum charge the farmer can use as much energy as he desires, whereas the fixed charge leaves a doubt in his mind as to what kind of service he is paying for.

A meeting to adopt plans governing rural-line rates will be held in Columbus on March 29.

## Hoover for Nitrate Production at Muscle Shoals

Secretary of Commerce Hoover, appearing recently before the appropriations committee of the House of Representatives, announced that he favored development of Muscle Shoals for making nitrates, although he was against government operation.

"I should like to see Mr. Ford do it if that would suit anybody," the Secretary said. "I do not know whether Mr. Ford's terms are the terms Congress ought to adopt. I could not speak as to that, but I would like to see anybody who has capital take Muscle Shoals and turn nitrates out of it tomorrow."

It was brought out that the United States has paid nearly $1,000,000,000 for Chilean nitrates since the Civil War, and the Secretary said that as a protective measure "we ought to do something for our own relief." He added that there was 4,000,000 hp. on the Colorado River in Arizona that he "would like to see turned into the manufacture of nitrates."

## Public Relations Program for New England Men

Seven addresses bearing upon public relations are scheduled for a luncheon and afternoon meeting of the New England Division of the N. E. L. A. at the Hotel Vendome, Boston, March 8. The luncheon will be served promptly at 12:30, after which the following program will be carried out: "Public Relations in Theory and Practice," by R. H. Newcomb, executive assistant Boston & Maine Railroad; "Co-operation by and with Our Educational Institutions," by M. S. Sloan, president Brooklyn Edison Company; "Employees' Clubs," by H. T. Edgar, Stone & Webster; "Women's Public Information Committee," by Miss G. M. Thibodeau, Malden Electric Company; "Publicity," by C. L. Edgar, president Boston Edison Company; "Knowing Your Contractors and Dealers," by George W. Hurn, resident manager Haverhill Electric Company.

## Nebraska Legislature Wants Ford to Develop Power

A resolution passed on Feb. 16 by the House of Representatives of Nebraska requested Henry Ford to make an industrial survey of the hydro-electric power of that state and to engage in its development, "pledging him the most cordial support from our government, state and municipal, and from our people." The resolution continued: "Resolved, That we urgently request the members of Congress from the State of Nebraska to support the passage of the Ford tender for Muscle Shoals before March 4, 1923, so that a precedent can be set for similar developments in Nebraska."

In response to this resolution United States Senator G. W. Norris, conspicuous for his opposition to the Ford proposal, sent a reply containing this among other statements:

"The resolution frankly states that the reason why you want the Nebraska members of Congress to support the Ford offer as to Muscle Shoals is 'so that a precedent can be set for similar developments in Nebraska.' The reason you give for the support of the Muscle Shoals proposition is one of the many reasons why I have been opposed to the acceptance of Mr. Ford's offer for Muscle Shoals. The acceptance of the Muscle Shoals offer, as you truly state in your resolution, would be a precedent which would be used as a basis for similar action all over the United States, and as a result we would give the control of the development of hydro-electric energy from our navigable streams over entirely to corporations of wealth without retaining any control or regulation whatsoever for the benefit of the people at large."

## Wisconsin Utility Men Get Ready for Convention

Nearly a thousand public utility men are expected to gather in Milwaukee on March 21 to March 23, when for the first time in the history of Wisconsin electric light and power representatives will unite with street railway and gas company delegates in a convention to be held by the Wisconsin Utilities Association, founded a year ago. The joint session will be addressed by President J. P. Pulliam, Milwaukee; C. R. Phenicie of Green Bay, chairman of the Electrical Section; B. W. Arnold, Oshkosh, chairman of the Electric Railway Section; James P. Barnes of Louisville, Ky.; John B. Malig of New Haven, Ind., and others.

Subjects already arranged for the electrical sessions include the safety code, rural extensions, automatic substations and inductive co-ordination. The sales and accounting sections will hear W. T. Bracken, Beloit, on "Selling the Commercial Department to the Employees"; W. E. Derwent on "Manufacturers' Relations to the Sales Department," and Inman P. Marking on "Customers' Meter Reading."

## New England Tie Lines

### Hartford and Springfield Soon to Be United by a 66,000-Volt Line—Large Energy Contracts

RAPID progress toward the wider interconnection of New England central-station and power systems is under way notwithstanding the severe winter conditions lately experienced. One of the most important tie lines to be built in the near future will interconnect the South Meadow station of the Hartford (Conn.) Electric Light Company with the 66,000-volt system of the Turners Falls (Mass.) Power & Electric Company at Agawam. This line will also tie the plants of the Hartford company and the United Electric Light Company of Springfield, Mass., together. As the Turners Falls system is interconnected with the New England Power Company's system, and the latter with the Boston Edison and Narragansett (Providence) systems, and as the Hartford company is interconnected with the Connecticut Power and Connecticut Light & Power systems, the completion of the Hartford-Agawam line will close the gap between various central stations in southern New Hampshire, in Vermont, on the Atlantic seaboard and in central New England and the properties in southwest Connecticut, leaving Maine as the only New England state pursuing a policy of isolation in electrical generation and transmission.

Important contracts for the sale of energy have lately been closed in the eastern Massachusetts region involving either the enlargement of existing facilities or the provision of new supplies. The Eastern Massachusetts Street Railway has arranged to buy local energy from the Lynn Gas & Electric Company, and the Edison Electric Illuminating Company of Boston has agreed to supply 10,000 kw. to the Eastern Massachusetts Electric Company, instead of the previous 3,000 kw., the latter company operating a tie line between Revere, Malden and Salem, Mass., and serving various Tenney companies at the north of Boston. An interconnection will shortly be made between the Salem Electric Lighting Company and the plant of the Beverly Gas & Electric Company, recently acquired by the Tenney interests, with probable early curtailment of generating functions at the small and less efficient Beverly station.

At a recent hearing in the Boston Edison rate case it was stated that an investigation is being made by the Boston Edison company and the Boston Elevated Railway Company relative to the feasibility of purchasing Edison service in case the proposed electrification of the Shawmut branch of the New York, New Haven & Hartford Railroad is undertaken. Another interconnection about to be effected is between the Boston Edison system and the Cambridge (Mass.) Electric Light Company, with an initial supply of 3,000 kw. to the latter.

## Europeans Impressed with Boston Lighting Bureau

So impressed were the members of the European "lighting mission" to the United States with the equipment and work of the Bureau for Better Illumination maintained in Boston that the establishment of an enterprise of this sort under the auspices of one or more technical societies in Great Britain will be taken up on the return of the vistors. The mission, which came to the United States late in January, is composed of W. E. Bush, British Thomson-Houston Company, London; H. Maisonneuve, Cie des Lampes, Paris; K. J. Corkery, China General Edison Company, Shanghai, and C. F. Johnston, International General Electric Company, London.

EUROPEAN LIGHTING MISSION VISITING IN BOSTON AND THEIR GUIDES

Left to right, front row—W. E. Bush, British Thomson-Houston Company; K. J. Corkery, Shanghai, China; H. F. Wallace, Boston; H. Maisonneuve, Paris. Back row—J. Danielson, Boston; H. H. Magdsick, Cleveland; G. L. Alexander, Schenectady.

# Electricity in Southern Cotton Mills

MORE than 60 per cent of the cotton-mill spindles in the territory served by the Southern superpower system—and there are nearly fourteen million in that territory—are operated on purchased power, according to a survey made recently by J. E. Sirrine & Company, engineers, Charlotte, N. C. Another interesting thing is that 5,250,000 of these spindles are served by the Southern Power Company. The 8,369,300 spindles which are operated on purchased power are owned by five hundred mills having an annual energy consumption of 683,233,000 kw.-hr. and an indicated load of 296,625 kva. From 80 to 100 per cent of the power for spindles is sold on a primary basis, while from 4 to 20 per cent is sold when power is available.

SURVEY OF CONDITIONS ON SOUTHEASTERN SUPERPOWER SYSTEM, WHICH SUPPLIES POWER TO 8,369,300 COTTON SPINDLES
(Made by J. E. Sirrine & Company, Engineers, Charlotte, N. C.)

## Hell Gate Still Grows

**A 35,000-Kw. Generator and a 35,000-Kva. Frequency Changer Will Augment Installation of 150,000 Kw.**

WITH the placing in service on Feb. 3 of a fourth turbine at the Hell Gate station, the initial installation at the United Electric Light & Power Company's ultra-modern generating plant on the East River, New York, was completed. This made a total installed capacity of 150,000 kw., which is one-half of the 300,000 kw. ultimate capacity. Already it is found necessary to increase the equipment further, and in the fall of this year an additional 35,000-kw., 25-cycle unit will be added. This unit is similar in a general way to those of the same frequency now in service and is being supplied by the General Electric Company. It will operate at 1,500 r.p.m. and will supply energy at 11,400 volts. This turbine will be arranged to bleed steam at two points to heat the feed water through the use of closed heaters. It will exhaust into a 50,000-sq.ft. Worthington condenser of the same general type now in service on two of the units. To drive this turbine there will be installed three boilers of 15,500 sq.ft. heating surface each, to be furnished by the Springfield Boiler Company. A change from the first installation of boilers furnished by this company has been made in the tube arrangement to allow for the addition of economizers. In the present installation a drop leg in the header allows for the superheater to be placed above the lower six rows of tubes. In the new installation the tube bank, instead of being twenty rows high, will be sixteen high with the superheater on top. A 13,824-sq.ft. economizer will be installed for each boiler. The economizers and the superheater are being furnished by the Power Specialty Company.

The stoker arrangement is also being changed from that of the original installation. The present boilers are each fired by two fourteen-retort, seventeen-tuyère stokers discharging into a central clinker-grinder pit. Each of the new boilers will be fired by a single fourteen-retort, thirty-three-tuyère stoker. The present sluicing arrangement of taking care of the ashes will be retained. These stokers are furnished by the same company that supplied the original installation, the American Engineering Company. Certain minor changes will be made in this new equipment as compared with the present installation, keeping pace with the advance in the art during the past year. For the new boilers it will be necessary to build another smokestack, the steel foundation for which has already been laid. The building was originally built for the complete installation of 300,000 kw., except that only that part of the electrical gallery was built which was necessary for the present equipment. This electrical gallery building at present consists of a service building at one end with four switch sections and one control gallery section. Each of the switch sections houses the switching equipment for one generator and twelve feeders. There will now be installed and equipped three more switch gallery sections of the same general design.

In order to make available the reserve generator capacity of the 60-cycle system for the 25-cycle system, and vice versa, a 25,000-kva. frequency changer has been purchased. This unit will run at 300 r.p.m. and will consist of one 60-cycle, 13,800-volt, three-phase alternator and a 25-cycle, 11,400-volt, three-phase alternator on a single shaft and with four bearings. On the same shaft will be installed a 25-cycle, 11,400-volt wound-rotor induction starting motor and a 115-kw., 250-volt direct-current exciter. A 17,000-kva., 14,000-volt, three-phase, 25-cycle transformer is connected between the stator of the 25-cycle unit and the rotor of the 60-cycle unit. This is the largest unit of its type that has been built, and its operation is looked forward to with interest. It is approximately large enough to act as reserve for the loss of the largest generator on either system. A separate building is being built to house this unit together with its transformers and oiling equipment.

A further addition to the equipment at Hell Gate station will consist of a bank of five three-phase, 12,000-kva. outdoor transformers which will be used to supply service to territory in Brooklyn and elsewhere.

# Refunding Figures in February Financing

ELECTRIC light and power public utility issues of bonds and stocks during the month of February amounted to $57,811,600, representing an increase of more than 88 per cent over February, 1922, but a decrease of more than 19 per cent as compared with January of the present year. Two ten-million-dollar issues swelled the month's total, a large part of which was for the purpose of acquiring or redeeming stocks or bonds already outstanding. Only nine of the eighteen securities listed represent applications for strictly new capital. The rise in popularity of preferred stock, which was one of the features of the trend of financial affairs in 1922, is still apparent. Long-term securities continue to predominate, and the rate of return yielded the investor, 6.25 per cent, though higher than in January, is still low.

SECURITY ISSUES OF ELECTRIC SERVICE COMPANIES IN FEBRUARY

| Name of Company | Amount of Issue | Period, Years | Class | Purpose | Interest Rate | Price | Per Cent Yield |
|---|---|---|---|---|---|---|---|
| Connecticut Light & Power Co. | $4,500,000 | .. | Cumulative preferred stock | To retire floating debt and for construction | 7 | 100 | 7 |
| Southern Indiana Gas & Electric Co. | 1,000,000 | 24 | First lien and refunding mortgage gold bonds, series B | Refunding and to reimburse for expenditures | 6 | 92 | 6.65 |
| Alabama Power Co. | 4,700,000 | 28 | First mortgage lien and refunding gold bonds | Additions, to retire floating debt and other purposes | 5 | 89½ | 5.75 |
| Ohio State Power Co. | 290,000 | 12 | First mortgage gold bonds of 1915 | Construction | 6 | 97½ | 6.30 |
| Southern Minnesota Gas & Electric Co. | 1,275,000 | 19 | First lien and refunding mortgage gold bonds, series A, sinking fund | To retire bonds and reimburse for expenditures | 6½ | 98½ | 6.60 |
| Monongahela-West Penn Public Service Co. | 6,770,000 | 5 | First lien and refunding convertible gold bonds, series A | To retire bonds | 6 | 97.89 | 6.50 |
| Charlestown Gas & Electric Co. (Mass.) | 200,000 | 20 | First mortgage gold bonds, series A | Refunding | 5 | 104½ | 4.65 |
| Electric Bond & Share Co. | 1,000,000 | .. | Cumulative preferred stock | General corporate purposes | 6 | 97½ | 6.15 |
| Pacific Gas & Electric Co. | 10,000,000 | 30 | First and refunding mortgage gold bonds, series C | Additions and extensions | 5½ | 98½ | 5.60 |
| St. Maurice Power Co. (Que.) | 9,026,600 | 30 | First mortgage sinking-fund gold bonds | Additions and extensions | 6½ | 99½ | 6.55 |
| Pennsylvania-Ohio Pwr. & Lt. Co. | 1,000,000 | .. | Cumulative preferred stock | To reimburse company for property expenditures | 7 | 93½ | 7.49 |
| Lake Sunapee Power Co. (N. H.) | 200,000 | 20 | First mortgage sinking-fund gold bonds | Additions | 6 | 94½ | 6.50 |
| Oklahoma General Power Co. | 1,000,000 | 29 | First mortgage gold bonds, series A | Additions | 6 | 92 | 6.23 |
| Continental Gas & Electric Co. | 2,000,000 | 25 | Refunding mortgage bonds, series A | Additions and extensions | 6 | 95 | 6.40 |
| West Missouri Power Co. | 1,350,000 | 20 | First mortgage gold bonds, series of January, 1923 | Refunding and new capital | 6 | 98½ | 6.13 |
| Philadelphia Co. | 10,000,000 | 15 | Convertible debenture gold bonds | Refunding | 5½ | 92½ | 6.25 |
| East Penn Electric Co. | 2,500,000 | 30 | First mortgage and refunding lien gold bonds | Additions | 6 | 97 | 6.20 |
| Indiana Service Corp. | 1,000,000 | 27 | First and refunding mortage gold bonds, series A | Additions and extensions | 5 | 88¼ | 5.88 |
| Total | $57,811,600 | | | | | | |

## Growth of Niagara Falls Power Company Continues

The annual report of the Niagara Falls Power Company puts its total output of electrical energy for 1922 at 2,252,248,525 kw.-hr., placing the company once more in first place among American power companies in production of electrical energy. This output compares with 1,855,120,000 kw.-hr. in 1921, when the company occupied second rank, and to its peak output of 2,328,326,000 kw.-hr. in 1920.

Earnings applicable to dividends after all charges including amortization were $2,394,407, an increase of $415,814 over 1921. There was no remarkable change in the current assets or liabilities as compared with 1921, the former being $6,789,174, an increase of $398,813 over the previous year, while current liabilities increased $282,757 to $1,831,379, leaving net liquid assets, as of Dec. 31, $4,957,789. Accumulated surplus amounted to $2,136,761.

During the year under the customer ownership plant the company sold to employees and consumers $3,664,300 7 per cent cumulative preferred stock.

The transforming station at Echota, which forms the center of the upper Niagara River power territory, was completed during the year and has a capacity of 200,000 kw. The new transmission line to Buffalo, which is carried across the Niagara River in two places on high steel towers, was also completed and the tunnel which is to supply water from the upper river has been bored through in full size for more than three-quarters of a mile. Other additions made to the plant during the year consist of three hydro-electric units, each of 70,000 kw. capacity, placed in the gorge of the lower river, which will be operated with water brought from the pool above the falls. It is expected that one of these units will be put into service in time for the seasonal peak load this coming autumn and the other two early in 1924.

## Niagara Falls Power Tunnel Almost Completed

Official announcement has just been made that the pressure tunnel from Port Day to the edge of the high bank of the Niagara River at Niagara Falls, N. Y., is nearing completion. This tunnel will carry the water for the new extension to the power development of the Niagara Falls Power Company, and it is expected that water will be admitted by the first of April. The tunnel is believed to be the largest water-power tunnel ever constructed, and the company wishes to afford engineers an opportunity to inspect it before it is put into service. With the co-operation of the Read-Coddington Engineering Company, which is the contractor for the work, an opportunity will therefore be given to engineers to visit the tunnel at any time between March 20 and April 1. It is requested that those desiring to make this inspection will send their names to the Niagara Falls Power Company, mentioning the date on which they would like to visit the work.

## Maryland Utilities Association Organized

Permanent organization of the Maryland Utilities Association has just been effected at Baltimore by a gathering of utility men numbering 170. Electrical, gas and water-supply men took part in the movement, which is designed for the interchange of ideas, discussion of problems and education of the public.

Officers of the new organization are as follows: President, Emory L. Coblentz, Frederick; vice-president, Charles O. Culver, Salisbury; secretary and treasurer, H. T. Connolly, Annapolis.

## Chamber of Commerce Takes Vote on Trade Bodies

Trade associations were the subject of a referendum submitted to its membership on Tuesday of this week by the Chamber of Commerce of the United States. Organizations representing practically all industries and branches of commerce form an important part of the chamber's membership, and a "yes or no" vote was taken on whether because of "their numerous useful and important functions of obvious propriety" trade associations should exist for each important branch of industry and commerce and on various subsidiary propositions affecting their control and functions.

It is pointed out in the committee report accompanying the ballots that "there is a long list of functions which trade associations perform in the interest of their members and of the community at large. These functions are illustrated by the standardizing and safeguarding of the quality of goods, the reducing of waste in manufacture and distribution, the promotion of trade, both domestic and foreign, and the upbuilding in scores of other ways of industry and commerce." In its report the committee opposes government control of trade associations.

## Coal Commission Asks More Funds to Finish Work

Although it still had $85,000 on hand, the President's fact-finding coal commission applied to Congress last week for a further appropriation, asserting that since the sum just named would be entirely inadequate to carry its investigations to a conclusion the commission was prepared to suspend its work on March 4 unless further funds were granted and to return the amount unexpended. The commission held that too many inconclusive investigations of the coal industry have already taken place and that unless the present one could be made thorough there was no use in going on with it. The sum desired by the commission and for which it guaranteed real results was $400,000. With this sum it proposed to send 250 men and women investigators into the coal fields to gather first-hand information on living conditions and everything affecting the fuel situation at the source.

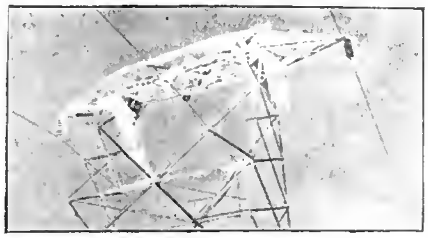
The coal commission has been made the recipient both of much matter in the nature of propaganda and of a great mass of helpful data. Among other things, its attention has been called to a widely held belief that coal operators have not made sufficient use of engineering skill. The record is said to be clear that expenditures for engineering talent and advice represent an insignificant portion of the expense of coal-mine development—very much in contrast with the amount expended for engineers in metal mining.

## Lightning-Arrester Committee in Steinmetz's Workshop

Left to right—E. R. Seymour, L. T. Robinson, D. W. Roper, F. L. Hunt, M. G. Lloyd, J. B. Taylor, E. E. F. Creighton, J. R. McFarlin, V. E. Goodwin, A. H. Sweetnam, F. B. Davenport, W. F. Hudson, R. T. Wagner, A. H. Perham, J. P. Fish, H. H. Bailey, E. H. Burger, members of A. I. E. E. committee and General Electric officials.

## Fog-Ice Deposit on Transmission Line Over Cascade Range

THE transmission line which Stone & Webster, Inc., are building across two mountain ranges to supply the Wenatchee Valley with power from the Puget Sound Power & Light Company's system is not yet complete, but some sections of the line have already withstood severe weather conditions. The accompanying picture was taken where the line crosses the Cascade Mountains at an elevation of 3,900 ft. A series of cold clear days last November were accompanied by moist winds blowing up from the lower canyons. When this moist air reached the cold zone at the higher elevations the moisture instantly congealed on contact with any solid object. The fog-ice hung from the conductor in icicles as long as 24 in. and several inches thick. When the picture was taken the ice had fallen from the conductors, but the peculiar formation of low-density ice on the tower can be plainly seen. The picture was furnished by W. D. Shannon, under whose supervision the line is being built.



FOG ICE ON TOP OF TRANSMISSION TOWER

## Engineering Foundation Re-elects Rand Chairman

Announcement has been made by the board of directors of the Engineering Foundation, which is directing a national program of industrial research in co-operation with the National Research Council, of the re-election as chairman of Charles F. Rand of New York, who is treasurer of the American Institute of Mining and Metallurgical Engineers. Other officers elected are: First vice-president, Edward D. Adams; second vice-president, Frank B. Jewett; treasurer, Joseph Struthers; assistant treasurer, Henry A. Lardner.

Alfred D. Flinn was re-elected a director of the Foundation. Dr. W. F. M. Goss was elected to the board to succeed George M. Basford, and Col. Arthur S. Dwight was named a director to succeed Edwin Ludlow. Other members of the board for the ensuing year are George H. Pegram, Bancroft Gherardi, Silas H. Woodard, Prof. Arthur L. Walker, John H. Barr, H. Hobart Porter, David S. Jacobus, Prof. Herbert M. Boylston, E. Wilbur Rice, Jr., Elmer A. Sperry and J. Vipond Davies.

## General Electric's New Plan for Employee Investment

To further investment by employees of the General Electric Company in the securities behind which the company stands a new plan has been worked out and the General Electric Employees' Securities Corporation has been organized. The new corporation will issue 6 per cent bonds to employees on the installment plan, paying an additional 1 per cent on them as long as the holder remains in the employ of the company. Seven of the fifteen members of the board of directors will be representatives of the employees, elected by the bondholders. Each $10 par value of such bonds of the new corporation will have one vote for these directors. Eight directors will be named by the company. The new corporation will issue $5,000,000 of 6 per cent fifty-year bonds and 10,000 shares of no-par-value capital stock. The proceeds from the sale of the stock and the bonds will be invested by the company in the securities of light and power companies and of holding companies in which the General Electric Company itself is financially interested. In other words, the idea of the investment trust will be followed, with the employees as participators in the profits through their holdings of the securities of the trust itself.

## Brief News Notes

**"Home Rule" for Fort Wayne Defeated.**—The Indiana State Senate has defeated by a vote of thirty to thirteen a bill designed to remove from the jurisdiction of the Public Service Commission all utilities owned by the city of Fort Wayne, introduced at the request of the city officials.

**St. Louis Bond Issue Carried.**—St. Louis will soon enter into an era of physical transformation and development as a result of the voters' approval on Feb. 9 of twenty of the twenty-one proposed items of the municipal bond issue for civic improvement. The sum voted aggregates $87,372,500 and includes $8,000,000 for a city-wide electric lighting system.

**"Home Rule" for Wisconsin Cities.**—The judiciary committee of the Wisconsin State Senate has, without a dissenting vote, recommended for passage a bill calling for submission to the people of a proposed constitutional amendment to give all cities of the state home rule in the control of public utilities. The amendment has already passed one session of the Legislature and if again approved will be submitted to popular vote next year.

**Annual Report of Metric Association.**—At the recent annual meeting of the American Metric Association, held at the Massachusetts Institute of Technology on Dec. 30, 1922, and reported in ELECTRICAL WORLD for Jan. 6, page 59, the name of the association was changed to Metric Association. The report of the meeting has now been published and is procurable from the association's office at 156 Fifth Avenue, New York City.

**Plant at Perryville (Mo.) Sold.**—The electric light plant at Perryville, Mo., a town of 2,000 people, which has been operated under the outlying-plants division of the Union Electric Light & Power Company, has recently been sold to Felix B. and Preston T. Holcomb, who also own and operate the Pike County Electric Company at Bowling Green, Mo. The purchasers will increase the capacity of the Perryville plant from 50 kw. to 100 kw.

**To Boost Washington Electrically.**—Ambitious plans to make the nation's capital also the electrical industrial center of the country are being advocated by the Electrical Contractor-Dealers' Association of Washington. Interests representing an approximate investment of $100,000,000 are involved, and the announced plan is to have Washington's electric interests stand as a co-operative unit devoting its efforts to "electrifying America."

**Another Pennsylvania Merger.**—The Northwestern Electric Service Company of Pennsylvania, with headquarters at Erie, has acquired by merger the People's Incandescent Light Company of the same city as well as three electric railway companies—the Northwestern Pennsylvania Railway, the Northwestern Connecting Railway and the Crawford County Railways. The new consolidated company is capitalized at $2,000,000 and will supply light, heat and power as well as trolley service.

**Proposed Tax of 10 per Cent on Oklahoma's Electrical Utilities.**—A tax of 10 per cent on the gross receipts of all companies engaged in the transmission or sale of gas or electricity is one of the provisions of a measure to tax public utilities recommended to the Oklahoma Legislature by Governor Walton. Telegraph and telephone companies he would tax to the amount of 15 per cent and street railway companies 10 per cent. The California law which Governor Walton cites in support of his plan taxes electric and gas utilities only 7 per cent.

**Muskogee Construction Proceeding Rapidly.**—Construction work on the new Muskogee plant of the Oklahoma General Power Company is being rushed in order to complete the intake condensing-water tunnels before the spring rise of the Arkansas River. If these tunnels can be completed and ends walled in before this period, the completion of the entire project by Aug. 1 is assured. The excavation for the tunnels is about 35 per cent completed, according to George F. Phythian, construction superintendent, and construction work on the foundation about 25 per cent. The capacity of the new plant will be 22,500 kw., divided between a 15,000-kw. and a 7,500-kw. unit. The 15,000-kw. unit will have a condenser cooling surface of 31,000 sq.ft., with a pump capacity of 40,000 gal. of water per minute.

**Municipal Plant Reduces Rates.**—A flat reduction of 20 per cent in the rate for electrical energy supplied to Bellefontaine, Ohio, by the municipal plant has been authorized by the City Council, effective March 1. The new rate for lighting purposes will be 8 cents flat; for power, a sliding scale from 5 cents down to 3 cents, with the 10 per cent discount for payment before the tenth of the month retained. The reduction was authorized after the report showed that the plant could be operated at a profit on these rates, based on earnings in 1922.

**Cedar Falls Turbine Shows High Efficiency.**—Tests on the 20,000-hp. Pelton single-overhung reaction turbine at the Cedar Falls extension plant of the city of Seattle have just been completed. This plant was placed in service in June, 1921, but for reasons beyond the control of either the city or the manufacturer final testing was delayed until a week or two ago. Notwithstanding that it has been in service for more than a year and a half, the unit was found to be in perfect operating condition, the absence of vibration being particularly noticeable. Water measurements were made by a weir installed permanently as a part of the power-plant equipment. A very satisfactory efficiency curve was obtained, the maximum exceeding 92 per cent.

**A Memorial to Niagara Power.**—City Engineer W. B. Bennett of Niagara Falls has advanced the idea that a suitable power memorial should be built on the state reservation at Niagara Falls to portray to the millions of visitors that come there yearly the importance of the hydro-electrical development now under construction. It is proposed to erect a duplicate of a section of the big water tunnel which the Niagara Falls Power Company is carrying a mile under the city of Niagara Falls. This tunnel reproduction would be about 100 ft. long, 32 ft. high and 32 ft. wide across the horseshoe, the height and width of the actual tunnel. The face of the memorial would be ornamental, representing the face of a cliff, but inside the tunnel would be lined in the same manner as the real one. The plan is to lead one of the reservation roadways into the model tunnel so that tourists could drive through it.

**H. P. Davis Has Broadcasting Plan.**—H. P. Davis, vice-president of the Westinghouse Electric & Manufacturing Company, who has been called the "father of broadcasting," has suggested a plan for the establishment of a national broadcasting service. He thinks that a federal regulating body should be formed along public service commission lines, and that two classes of broadcasting stations should be recognized—national and local. In the first class Mr. Davis would include a limited number of stations of considerable power with wave lengths arranged so that they will not interfere at any point and located where program material will always be available. These stations could transmit on the present wave lengths of 360 m. or 400 m. and also on a wave length that can be relayed. To the local stations should be given wave bands that will permit existing receiving apparatus to tune in on them, but these wave bands should be separated sufficiently from the national stations to allow no interference.

**Los Angeles Utility's Earnings Increase 31 per Cent in 1922.**—In a report to stockholders just issued by the Pacific Lighting Corporation, of which the Los Angeles Gas & Electric Company is a subsidiary, an increase in electric sales in 1922 of 31.1 per cent over 1921 is shown. During the year there was a net gain in electric meters of 12,875 and 487 miles of wire was added to the system. The large increase in both the gas and electric departments necessitated large additions to the manufacturing and distribution systems. The net capital expenditures amounted to $10,908,476. The Pacific Lighting Corporation at the end of the year had neither a floating nor a bonded debt. The Los Angeles Gas & Electric Corporation had a net bonded debt of $23,905,500, an increase for the year of $6,937,500. It had floating liabilities, practically all of which were for current items, of $2,405,931, and had current assets amounting to $3,573,499. On the same date there were cash and bonds in its sinking funds amounting to $1,059,912.

# Associations and Societies

**Middle West Division, N. E. L. A.**—The annual convention of this geographic division has been set for St. Louis April 11 and 12.

**Canadian Electrical Association.**—This association will meet for its thirty-third annual convention at the Mount Royal Hotel, Montreal, on June 20.

**American Electrochemical Society.**—H. W. Gilette of the United States Bureau of Mines will give a talk on "The Electric Furnace in Non-ferrous Metallurgy" at the meeting of the Pittsburgh Section of the American Electrochemical Society on Thursday evening, March 8.

**Missouri Men to Hold Convention on River.**—The Missouri Association of Public Utilities will hold its next convention on May 24-26 on a Mississippi River steamboat starting from St. Louis at 8 p. m. May 23, going up the Mississippi and Illinois Rivers to a point above Peoria, Ill., and reaching St. Louis on the return trip at 5 p. m. May 26.

**Columbus Forms Illuminating Section.**—The first meeting of the newly formed Columbus Section of the Illuminating Engineering Society was held at the Engineers' Club on Feb. 20. Ward Harrison, president of the national organization, spoke. The officers of this section are: Chairman, G. F. Evans; secretary, R. C. Moore; members of the board, Prof. F. C. Caldwell, G. A. Sulzer and K. A. Piez.

**Next Foreign Trade Convention to Be Held in New Orleans.**—The tent national foreign trade convention of th National Foreign Trade Council wi be held this year in New Orleans May 2 to May 4, according to offici announcement. As in former year leading foreign traders from every pa of the United States and every line industry, as well as a considerable nur ber of business men from foreig countries, will be in attendance at th convention. The main theme of th convention will be "European Cond tions as Relating to World Trade."

**Southwestern Division, N. E. L. A.**—Among the speakers scheduled for th convention of the Southwestern Ge graphic Division of the N. E. L. A., be held at Oklahoma City on March to 16, are Executive Manager Ayle worth and W. J. Canada, of N. E. L. headquarters; A. K. Baylor, chairm of the national wiring committee; Bri Gen. G. H. Harries, vice-president H. Byllesby & Company; J. W. Gleed, re resenting the Bell telephone interest Earle W. Hodges of Arkansas, a possibly S. M. Kennedy, vice-preside Southern California Edison Compa Governor Walton of Oklahoma wi make the opening address.

## Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

Oklahoma Utilities Association—Oklahoma City, March 12-14. O. D. Hall, 1106 F t National Bank Bldg., Oklahoma City.

Southwestern Division, N. E. L. A.—Oklahoma City, March 14-16. S. J. Balling, San Antonio Public Service Co., San Antonio, Tex.

Illinois State Electric Association—Chicago, March 14-15. R. V. Prather, 305 Me Workers' Bldg., Springfield, Ill.

Wisconsin Utilities Association—Milwaukee, March 22-23. John N. Cadby, 445 Washington Bldg., Madison.

Tri-State Water and Light Association—Birmingham, April 17-20. W. F. Stieglitz, Columbia, S. C.

American Physical Society—Washington, April 21. D. C. Miller, Case School of Applied Science, Cleveland.

American Institute of Electrical Engineers—Spring convention, Pittsburgh, April 24-26; annual convention, Swampscott, Mass., June 25-29; Pacific Coast convention, Del Monte, Cal., Sept. 25-28. F. L. Hutchinson, 33 West 39th St., New York.

Middle West Division, N. E. L. A.—St. Louis, April 11-12. H. M. Davis, Bankers' Life Bldg., Lincoln.

American Electrochemical Society—New York, May 3-5. Colin G. Fink, Columbia University, New York.

Southwestern Public Service Association—Fort Worth, Tex., May 15-17. E. N. Willis, 403 Slaughter Bldg., Dallas, Tex.

Electrical Supply Jobbers' Association—Executive committee and general meeting, Hot Springs, Va., May 21-25. Franklin Overbagh, 411 S. Clinton St., Chicago.

Missouri Association of Public Utilities—River boat from St. Louis to Peoria, May 24-26.

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

Electric Power Club—Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

Pacific Coast Electrical Association—San Francisco, June 19-22. S. H. Taylor, 27 Rialto Bldg., San Francisco.

Canadian Electrical Association—Montreal, June 20. Louis Kon 65 Mill College Ave., Montreal.

## Commission Rulings

**Invasion of Territory.**—Under this eading there was printed in this column st week an account of a dispute beveen the Morris & Somerset Electric ompany and the Commonwealth Elecic Company which was adjudicated the Board of Public Utility Commisoners of New Jersey. By an inadertence the facts of the case were just eversed. It was the Commonwealth lectric Company which brought the omplaint against the Morris & Somerst Electric Company, the latter comany being the one which had a contract ith the Millburn Electric Company, nd the decision of the utility commison was in favor of the Morris & omerset company, the complaint of e Commonwealth company being disissed. The trend of the commission's ecision was correctly given.

**Oregon Commission Orders Adoption Parts of National Electrical Safety ode.**—The Public Service Commission f Oregon has determined that "all les previously adopted by it governing verhead and underground construction hould be annulled and canceled, and at the 'Definitions of Special Terms' Sec. 1), 'Rules Covering Methods of rotective Grounding' (Sec. 9), 'Rules or the Installation and Maintenance f Electrical Supply Stations and quipment' (Part 1) and 'Rules for the nstallation and Maintenance of Overead and Underground Electrical Suply and Signal Lines' (Part 2) of the lectrical Safety Code are in all repects adequate, just and reasonable nd should be adopted in lieu thereof." t has therefore ordered all public tilities within its jurisdiction which re affected by the sections of the code ited to comply with their provisions.

**Close Account of Utility Expendiures Maintained by California Comission.**—In line with its policy of eeping a close account of the expenitures of all public utility corporations n the state, the California Railroad ommission has ordered that utilities ith a gross annual operating revenue f $100,000 or more shall report the ames and titles of all officers or emloyees receiving a yearly salary of 5,000 or more, together with the mount of their expense accounts and ny contingent fees and a statement of heir duties. The same rule is applied o utilities whose gross income is beween $25,000 and $100,000 except that he minimum salary to be reported is ade $3,000. All utilities in these two lasses must file a statement showing or each of the years 1920, 1921 and 922 the total of donations, subscripions and contributions of all kinds and he total payments to attorneys, both of aid totals to be distributed to acounts as charged on the utilities' books uring 1920, 1921 and 1922. In addition they are ordered to file a statement showing the amount of cash they had for all purposes on Dec. 31, 1922, the names of banks or other financial institutions with which such cash was deposited and the rate of interest received, and the amount of cash in the treasury.

**No Universal Rule to Apply to "Going-Concern" Value.**—Declaring that the "going-concern" value of every business and of every utility depends on the features of that particular utility, the Alabama Public Service Commission, in its recent valuation of the property of the Alabama Power Company, declared: "If it has cost the company nothing to produce its business, if it has no valuable organization of employees or established credit, if it has not gone to any expense in advertising, soliciting or demonstrating for the purpose of educating the public to the use of the company's facilities, its going-concern value is bound to be affected thereby. The commission cannot therefore accept as sound a percentage basis of arriving at the going-concern value of this company."

**Falling Prices as They Affect Rates.**—Denying a petition of the Central Illinois Light Company for increased gas rates, the Commerce Commission of Illinois said: "These are abnormal times and we are dealing with rates for the future. The commission must therefore take cognizance of the fact that since the filing of the application for increased rates there has been a material reduction in the price of commodities that enters into operating costs." Holding that, with the exception of fuel, the trend of operating costs for material and labor is downward, the commission went on: "Moreover, the burden of making up the losses brought about primarily by the world war ought not to fall wholly on the company's patrons; in other words, part of this loss ought to be borne by the company. . . . Present economic conditions are temporary, are constantly varying toward pre-war levels, and therefore it would be inexpedient to predicate rates thereon."

**Getting at Value of Flowage Rights and Dam Site.**—In its valuation of the property of the Wisconsin-Minnesota Light & Power Company to be taken over by the city of Rice Lake, Wis., and run as a municipal electric plant the Wisconsin Railroad Commission found the valuation of the water-power development, including dam site and flowage rights, one of extreme difficulty as the range of estimates was very wide and was further involved by the operation of storage reservoirs on the headwaters of the river. For the company, a total value of the water power, including storage and land, as high as $237,000 was claimed. The city engineer pointed out that it was assumed that the storage reservoir above Rice Lake would be entirely filled and emptied once a year and called this a very doubtful assumption. He also alleged an unsatisfactory condition of the dam. Rejecting a steam-plant comparison and using one based on oil-burning equipment, he arrived at a water-power value of $35,000, including flowage rights and dam site. On a basis of purchase of energy on transmission lines from another company he reached a value of $20,000. His final conclusion was that $30,000 was adequate for the water-power value, including flowage and dam site. The commission finally concluded that the water-power value, including flowage rights and dam site, should be placed at $55,000. Severance damages to the power company running from $12,000 to $15,000 were found proper by the commission.

## Recent Court Decisions

**Commission Order Requiring Installation of Water Meters Overruled.**—In Elizabethtown Water Company vs. Board of Public Utility Commissioners of New Jersey an order of the board requiring the water company to install meters was overruled as unreasonable, because, the court said, the undisputed evidence showed that the company was financially unable to purchase the meters and that it could not procure the necessary money. (119 At. 284.)*

**Appeals from Oklahoma Commission.**—Proceedings by the Quinton Relief Oil & Gas Company to review an order of the Corporation Commission of Oklahoma revoking without notice a former order have been dismissed by the Oklahoma Supreme Court on a question of procedure. The court points out that under the constitution and laws of the state appeals from commission proceedings must be taken in the same manner as appeals from district courts; i.e., by petition in error. (211 Pac. 493.)

**Overflow Damages, Temporary or Permanent.**—In Bennett vs. Louisville & Nashville Railroad Company, an action for damages because of the overflowing of crops through the alleged faulty construction of an embankment, the Court of Appeals of Kentucky found that whether temporary or permanent damages resulting from overflow are allowable is dependent on the nature of the structure causing it. If a permanent structure properly built, a single recovery in permanent damages is allowable; if intended as permanent and unlawfully or negligently built, or if a temporary structure, temporary damages are recoverable as injuries occur, the question of whether construction was negligent in any event being for the jury. Where the cost of repairs necessary to remedy negligent construction is in excess of any damage to the property involved, the court should instruct that such cost is unreasonable and permit damages for permanent injury. (246 S. W. 121.)

# Men of the Industry

Changes in Personnel
Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry

## Medal for Lee de Forest

Dr. Lee de Forest, inventor of the audion or three-electrode vacuum tube for the amplifying of minute electrical currents and pressures, received the Elliott Cresson medal on Wednesday, Feb. 21, awarded to him by the Franklin Institute of the State of Pennsylvania. The presentation address was made by Dr. Walton Clark. A special committee, headed by Charles E. Bonine, appointed to investigate the audion reported that the invention of the three-electro vacuum is one of the most important ever made in the field of electrical transmission of intelligence and through its development has worked a profound revolution in the art of radio communication. Dr. Lee de Forest has been a pioneer in radio activity. He was born in Council Bluffs, Iowa., in 1873 and was graduated from the Sheffield Scientific School of Yale University in 1896.

**C. A. Bigelow** of Stone & Webster, Inc., has returned from Japan, where he has been associated with the Shogawa water-power development.

**S. Barfoed,** chief engineer for F. G. Baum, consulting hydro-electric engineer, San Francisco, is at present in Europe, visiting large hydro-electric developments.

**H. S. Walker,** former member of the sales force of the Denver office of the Westinghouse Electric & Manufacturing Company, has been transferred to the Salt Lake office of the company.

**Col. Charles H. Tenney,** of Charles H. Tenney & Company, Boston, was decorated with the distinguished service medal Feb. 21 at Springfield, Mass., by Assistant Secretary of War Wainwright, in recognition of his services in the Ordnance Department during the world war. The citation accompanying the decoration was read by Brig.-Gen. W. S. Pierce, assistant chief of ordnance, U. S. A.

**Eugene A. Yates,** who recently succeeded W. N. Walmsley as general manager of the Alabama Power Company, was elected vice-president and general manager of the company and was added to the board of directors at the annual meeting of the board held in Birmingham on Feb. 20. The following officers were re-elected: President, Thomas W. Martin; vice-presidents, R. A. Mitchell and W. N. Walmsley; treasurer, Robert M. MacLetchie, and secretary, Lamar Aldridge.

**William McClellan** and **Peter Junkersfeld,** consulting engineers of New York City, left on Saturday, Feb. 17, for Porto Rico to make final arrangements relative to the completion of the electric railroad which the firm has been building on the island. The railroad, which is virtually completed now, extends from San Juan to the outlying mountainous regions. In connection with this construction work Mr. McClellan made two previous trips to Porto Rico during the last few months. His present trip is partly one for rest.

**C. T. Jones,** formerly of the engineering department of the Northern Texas Traction Company at Fort Worth, is now in the engineering department of the El Paso Electric Company as distribution engineer.

**William Q. Gallaher,** formerly chief engineer for the West Virginia Public Service Commission, has taken charge of the "frigidaire" department of the H. & S. Electric Company in the Charleston district.

**P. I. Robinson,** formerly manager of the Fort Madison Electric Company, has been appointed manager of the Baton Rouge Electric Company, and Walter M. Bird, formerly of the Savannah Electric & Power Company, has been appointed manager of the Fort Madison Electric Company.

**G. J. Newton,** who has been associated recently with the Philadelphia Electric Company on underground distribution work, has joined the engineering department of the George Construction Company, Inc., of Philadelphia. Mr. Newton has been associated with underground distribution work for more than twenty years. He will have charge of the designing department.

**James Orr** has been appointed superintendent of power for the Hartford (Conn.) Electric Light Company, succeeding F. M. Wilbraham, who recently resigned the post to act as consulting engineer for the company. Mr. Orr has been in the company's service for more than a year, having previously been on the staff of Stone & Webster, Inc. Mr. Wilbraham is widely known in central-station power-plant circles and has been with the company many years.

**John W. Carpenter** of Dallas, vice-president and general manager of the Texas Power & Light Company, was recently appointed by Governor Neff to the board of regents of the new Texas Technological College. Mr. Carpenter is active in a widespread effort for the construction of cotton textile mills in Texas. He has made thorough studies of textile-mill conditions in New England and the Carolinas and has brought mill men to Texas to look over the situation, with the result that several such mills are now in process of organization, most of the proposed plants being designed to operate with central-station electric power.

**F. D. Knight** has been appointed superintendent of construction of the new power station of the Edison Electric Illuminating Company of Boston at Weymouth.

**Charles P. Dunn,** formerly connected with the city of Seattle's Skagit development in the capacity of hydraulic and structural designer, has become head of the drafting department of the Portland Railway, Light & Power Company.

**George W. Saathoff,** construction engineer for the Cities Service Company, which operates the Denver Gas & Electric Light Company, recently arrived in Boulder, Col., from New York, to inspect the site for the four-million-dollar steam plant which the Denver utility plans to erect near that city.

**K. W. Kissick,** chief engineer of the Sheridan County Electric Company for the past two and a half years, has been appointed manager of the Deming (N. M.) Ice & Electric Company, succeeding R. E. Thompson, who resigned to become manager of the Springfield (Mo.) Gas & Electric Company.

**A. Strauch,** formerly electric heating specialist for the Pacific Gas & Electric Company, has opened offices in the Rialto Building, San Francisco, as an electric heating engineer. Mr. Strauch was in charge of the development of electric heating and cooking for the Pacific Gas & Electric Company for eight years.

# Obituary

**Guilford S. Wood,** president of the Southern Sierras Power Company, died recently. Mr. Wood was one of the original incorporators of the Nevada California Electric Corporation, which is the parent company of the Southern Sierras Power Company.

**Arthur M. Leacock** was killed by gas on Thursday morning, Feb. 22, in a room occupied by him at the plant of A. M. Leacock & Company, manufacturers of electrical appliances. Mr. Leacock, who was president of the company, was accustomed to devote time in the evenings to the study of improvements on electrical appliances, using the room fitted up by him for that purpose. It is believed that when he entered the room he turned on the jets in a small gas heater but failed to ignite them.

**Dr. John Trowbridge,** professor of physics at Harvard University for many years and for twenty-two years director of the Jefferson Physical Laboratory in that institution, died at Cambridge, Mass., Feb. 18, at the age of seventy-nine. Professor Trowbridge became an assistant in mathematics at Harvard in 1866, was assistant professor of physics at the Massachusetts Institute of Technology 1869-70 and taught physics at Harvard from 187[illegible] to 1910, when he was made professor emeritus and honorary director of the Jefferson Laboratory.

# Prices or Profits on Electric Ranges?

**Lapse of Marsh Patents Will Not Change Market Conditions—The Opportunity Calls for "Quality" Goods and Prosperous Dealers, Not Cheap Ranges**

By L. D. Smith

Secretary and General Manager Standard Electric Stove Company, Toledo, Ohio

THE twelve or fifteen years' experience I have had in the electrical cooking business inclines me to believe that all range manufacturers have tried to make their respective appliances as good as possible. Considering the magnitude of the undertaking and the resistance in the market, I think that the general acceptance of the electric range idea has made wonderful progress.

So far I presume that most observers will agree. But we now see an unwise and uninformed element coming into the business with the idea that the public can absorb a cheap electric range. Even some of the oldest of the present manufacturers are advising their trade to "wait and see what we are going to make for $99—something that every workingman can buy," and more along similar lines.

It happens that 54 per cent of our families have average incomes of $920 per year. I do not believe that these families can afford to use electricity for cooking purposes at any rate for which the lighting company can distribute it today, and to my way of thinking it would be an "unwise service" to the customer and an "unwise investment" to the lighting company to install an electric range in these homes on any easy-payment plan. Homes of this class too often have "wasteful ways," and the after-sale service alone would in too many cases be a hardship which the dealer could not long endure.

In giving the best service to a customer the customer's capacity to use the article should be considered. I see no present market possibility for a cheaply made electric range. Being cheaply made, it would quickly be out of order, it would consume more energy, bills would be higher and the user be correspondingly dissatisfied.

L. D. Smith

A user's dissatisfaction entails additional expense on the lighting company for service, repairs, apologies and out-of-use conditions, all involving again an increase in rates. I think the lighting companies have in the main been wise in guarding their users against the shoddy in electrical appliances and that it is supremely to their interest to discourage any attempts to dazzle the blind with poor quality electric ranges.

### Market Is for Quality

If memory serves me rightly, about 20 per cent of American families have incomes of $3,000 to $10,000 per year, and it is to this class of families that the electric range makes its first appeal. These families include the thrifty, discriminating class, and when they buy they select carefully with an idea of permanency and beauty. They want the best and cleanest finish and the most durable construction. They never have absorbed and never will absorb the low-priced article. They are always buyers of the best and take the best care of it, prize it most highly and pay for its repairs.

The lighting company, the jobber and the dealer ought in self-protection to saturate this 20 per cent market with the best the most experienced manufacturers can make before they experiment with what might be done by some one "proceeding along new lines" with a low-price rainbow to catch the workingman demand. I take it that when this is done there will be time enough to sell ninety-nine-dollar ranges.

### Profit Means More than Price

One need not disparage the ambitious gas-range manufacturer who finds his gas-stove business declining and wishes to go into a better thing. But up to date such advance as the electric range business has made was not made by him but in spite of him. He has not as yet merited the confidence of the electrical trade in any instance that we know of. If he can give the electrical public a convincing demonstration of better value, we certainly want it no matter who makes it; but we certainly do not want to load the public up with unsatisfactory appliances from any source. One must also remember that satisfaction to the user means many things. It means first a fair return to the manufacturer, a fair return to the distributing sales force and a full measure of return for the dealer service rendered. Otherwise none of these remain to render it and it is not given or received.

We are all here because each supplies, and has supplied, a want not possible to fill otherwise. The "Three Graces" cited above are just as essential to trade as faith, hope and charity are to morals, and I for one do not like to see one trying to strangle the other in the interest of low prices, or all gasping for breath in the interest of low prices on some gas-stove manufacturer's departure.

A "low-priced" range is an invitation to do business below cost. It encourages bad practice in the factory and poor service from the

dealers, who should be in a position to give the best. A poorly conceived electric range will be thrown back on the lighting company no matter who makes it. We have sufficient evidence of this in localities where the lighting companies have in previous years established cooking rates as low as 2 cents per kilowatt-hour in order to move them. In these localities the interest in and use of the electric range is not so great today as in many other localities where rates are 100 per cent higher. The lighting company must have a sufficient return from its range customers to justify the service they receive and must give a certain service not to be secured otherwise.

We have never urged a low rate in order to sell electric ranges. The range load is a profitable load to the light company, provided the range they install is a "bang-up," well-conceived and well-made article and installed in that class of homes that we classify as housing 20 per cent of our population. Something like four million ranges can find useful employment in these homes, and when all are filled and satisfactory service is rendered we can begin all over again. I should like to see the electric range become "class conscious" and the electrical trade united to discourage the efforts of any manufacturer who tries to make something competitive in price with gas or gasoline stoves.

### Prices of Ranges Should Go Up

A great many of the trade are under the impression that since the Marsh patent contracts have expired electric ranges will be considerably reduced in price. It must be remembered, however, that the licensers derived their income from royalties paid by manufacturers and they really were interested in a substantial remittance. The royalties depended on the sales and hence it appeared to be expedient to offer the user as low a price as was at all consistent in order to get the maximum royalty. Therefore, in the past, the jobber's margin of profit has been fixed very low. The dealer likewise was given a short discount and the manufacturers' lists were less than they should have been on a nominal volume.

The manufacturers who are selling at licensers' lists at regulated discounts have had no funds for publicity, the jobber has had no margin of profit for special sales work, and the dealer has not felt that his margin was sufficiently large to permit him to give reasonable service.

We do not know what action others are taking, but our list prices are being increased, and we feel that it is distinctly for the good of the range business.

# The Gypsum Case as a Guide

## Why This Decree Means Nothing to the Trade Association Member—A Simple Rule of Conduct for the Observance of Business Men

By Franz Neilson
Counsel Association of Electragists International

Wide publicity has been given to the "consent" decree in the "gypsum case" under the mistaken belief that for the first time a concrete case has been decided in the courts furnishing a "yardstick" by which to judge just what can be done by trade associations and what cannot be done by them under the seemingly puzzling anti-trust laws. The district attorney in this case is credited with the remark that "this decree is a death knell to the trade association." On the other hand, Samuel Untermyer is reported to have said in effect that, so far from being the death knell of the trade associations, it marks the passing of the Sherman anti-trust law.

### Decree No Guide Whatever

When doctors so eminent disagree what shall be done about it? For one thing, it may be well to recall a few fundamentals and do some thinking for ourselves to see whether or not it is all a tempest in a teapot. In the first place, there is no "decision" by any judge in this case. Decisions are rendered by the court on litigated questions of law or fact. Decisions deliberately arrived at on matters in dispute are entitled to great respect, especially when accompanied by opinions stating the important facts found and the conclusions of law. Counsel and laymen in other cases with similar facts will find such decisions helpful as indicating what rulings of law they may confidently expect in their own cases.

But this is a "consent" decree. It means nothing of any importance to any one save the parties to the suit. It means that the defendants agreed to submit to such decree without putting up any fight. It does not even mean that the judge who signed the decree gave it any thought. It is no guide whatever to other business men and trade associations unless the facts in their case are precisely like those in the gypsum case. If the decree represented a judgment following determined litigation on matters in dispute, it would be regarded as very significant and would become the leading case in anti-trust-law questions. But it was not such a judgment. There was no litigation. The decree therefore constitutes no precedent whatever. In any new case to be adjudicated the court would proceed exactly as if there were no gypsum "consent" decree in existence.

The gypsum decree is thus, I repeat, of no help whatever as a guide. It represents an agreement between the gypsum people and the government as to what they will refrain from doing hereafter. It can have no application to any other trade unless that trade finds it is doing precisely what the gypsum people did and prefers to arrive at an agreement with the prosecuting authorities rather than to have any and all points in dispute adjudicated before the court.

The anti-trust laws are really not so puzzling to business men who have given thought to them. They merely prohibit "restraint of trade," which usually follows the fixing of prices, the maintaining of prices, the apportioning of territory among competitors, the allocating of customers to competitors, etc. The significance of such acts in connection with the interpretation of the laws had been pretty well grasped by lawyers and students of various decisions before the gypsum decree appeared. Ordinarily the business man who has given thought to this broad question is conscious of the true answer when a question of legality arises.

### A Rule of Conduct

My office long previously expressed a simple rule of conduct for members of trade associations desirous of

legitimately exchanging price information, to wit:

The members may meet, contribute, compile and publish facts, including past prices and other statistics; but there must not be any agreement or concert of action respecting prices to be charged, apportionment of territory, allocation of customers, punishment of competitors, limitation of output, etc. Each member by himself and uninfluenced by the others must arrive at his own conclusions from the facts he has received and decide for himself what he will do; and this without communicating his decision by word or sign to the others.

In other words, each member will use the information gained through the association in the same way that he uses information gained from all other sources, including trade reports in newspapers, gossip in the trade, salesmen's reports, confidential investigations, and so on.

# Business Conditions

**A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand**

## Farm-Lighting Plants Gaining Ground in Foreign Countries

The increasing amount of farm-lighting plant business being placed in foreign countries by manufacturers of the United States is shown in reports recently issued by the Bureau of Foreign and Domestic Commerce. On Feb. 26 the bureau issued a statement on the possibilities of these foreign markets and showed that certain South American countries, Australia, Mexico, Cuba, Java, the Straits Settlements, India and Ceylon are markets in which the farm-lighting plant is making considerable progress. As an indication of the volume of business done throughout the world, the total exports of farm-lighting sets from the United States during 1922 were valued at $441,569, of which $123,934 worth went to Australia, $1,727 to Brazil, $10,570 to Cuba, $27,658 to Mexico, $21,040 to Argentina, $14,851 to India, $7,811 to the Straits Settlements and $15,910 to Spain.

According to the survey made by the government officials, rural districts in many foreign countries offer increasing possibilities for the sale of the plants. Where the land is worked in large holdings, as in the case of sugar and rubber plantations, the demand is for isolated plants, which may range in capacity from ½ kw. to 50 kw. or even 100 kw. Where the rural districts are highly cultivated and thickly settled, there is a growing tendency to build distribution lines out from nearby central stations.

In connection with the successful marketing of farm-lighting plants abroad it is important that arrangements be made not only for aggressive representation but for a certain amount of service, especially where storage batteries are a part of the installation, according to government surveys.

## Spotty Conduit Stocks Prevail

Nothing like well-rounded stocks of rigid conduit are reported at this time, and the farther one gets from the steel mills the more uneven the supply of pipe appears to be. In some places the shortage of both black and galvanized conduit in the ¾-in. to 1¼-in. sizes is very acute and few orders of substantial size can be filled without a lot of "shopping around" among jobbers.

Prices are firm as a result. The heavy traffic burden upon the railroads, combined with the large business the steel mills are handling in many lines, makes the early accumulation of reasonably complete stocks little more than a dream for the jobber far distant from the steel-producing centers.

The increasing popularity of pipe is a marked feature of the building revival of the past few months. There seems to be no immediate prospect of acquiring satisfactory stocks, but as the rigors of winter disappear improved deliveries by rail will unquestionably relieve the situation, to some degree, at least as regards the more pressing construction jobs.

## Comparative Prices of Station Supplies

| | Current Price | Four Weeks Ago | One Year Ago |
|---|---|---|---|
| Soft steel bars, per lb. | $0.0303 | $0.0296 | $0.0247 |
| Cold finished shafting, per lb. | 0.0397 | 0.0378 | 0.0336 |
| Brass rods, per lb. | 0.1804 | 0.1742 | 0.155 |
| Solder (half and half), per lb. | 0.2617 | 0.2425 | 0.2075 |
| Cotton waste, per lb. | 0.1181 | 0.1175 | 0.106 |
| Washers, cast iron (¼-in.), per 100 lb. | 4.33 | 4.33 | 3.83 |
| Emery, disks, cloth, No. 1, 6-in. diameter, per 100 | 2.96 | 2.96 | 3.11 |
| Machine oil, per gal. | 0.349 | 0.36 | 0.40 |
| Belting, leather, medium, off list | 49% | 49% | 46% |
| Machine bolts, up to 1-in. x 30-in., off list | 51⅓% | 51⅓% | 64⅔% |

## Well-Sustained Demand for Motors

**Absorption of Motors Into Diversified Industries Continues to Feature Current Business**

Absorption of motors into diversified industries continues to feature current business, the demand being concentrated mainly into size ranges below 10 hp. At present motor stocks are substantial, although deliveries in the North are handicapped by railroad embargoes and highways obstructed by snow and ice. Competition is acute for the business available, and complaint is heard in some quarters that the margin between factory and list prices is unsatisfactory. There is also some discussion going the rounds relative to the granting of credits by manufacturers in territorial sales not directly negotiated by motor agencies, there still being some difficulty in assigning such credits under sharply competitive conditions.

The introduction of new motors into the market is also in evidence in some quarters, and the older lines are meeting this competition by increased attention to application engineering and to insistence upon high-grade construction. Some of these new motors have captured the business on the basis of one or two special features peculiar to their design, and at present the designing engineers of motor manufacturers generally are becoming more and more impressed with the demand of the user for maximum reliability of service. In the textile field sales have been gratifying, one manufacturer having recently received an order for 1,050 loom motors and one for 225 motors for the direct driving of carding machines.

### No Shortage of Steel

No reports have been received of late as to shortages of steel, copper or insulating material used in motor construction, but under present railroad conditions factory purchasing agents are obliged to look well ahead in ordering raw material. The larger companies usually maintain stocks of steel adequate for all ordinary demands for motors. The tendency of raw-material costs is upward, and labor shortage in the unskilled and skilled fields alike is making some impression upon the industry. Prices of motors have not changed much lately, barring occasional cuts to move stocks under very sharp competition. This competition acts as a deterrent to sporadic price advances for the time being, but the feeling is far from local that the present volume of business is being done at a relatively low margin of profit. Therefore the price outlook is uncertain, with strong pressure on the buyer's side to hold orders subject to quotations at or near current levels, and, on the other hand, a pressure within the trade to realize more satisfactory margins of profit on the business in sight.

In well-informed circles it is believed that the unsaturated condition of industry as regards proper motor appli-

cations will stabilize production for a long time to come. An immense number of industrial and mercantile establishments remain to be equipped with suitable motor drives and collateral control equipment. This includes numerous installations which should be periodically analyzed from the standpoint of changing interior loads, modifications in load factor and power factor. Progressive motor-sales engineers realize that in the readaptation of drives toward wider use of individual motors on tools and other machines lies a field of exploitation which will be permanently useful to the industry and to the owner alike. The movement toward the substitution of alternating-current motors for direct-current units continues, and new applications of motors in paper manufacture, in the textile field and elsewhere are now featuring this important branch of the electrical industry.

## The Metal Market

**Active Demand Continuing to Force Prices Higher—Talk of Quotation Above 17 Cents**

Active demand for copper is forcing prices higher, so that 16.37½ cents is quoted for electrolytic. Some producers are asking 16.50 cents. Domestic demand shows no signs of abating. Buying continues to be for prompt March and April shipment, and so far as can be learned is to meet requirements of business already booked or firmly in hand.

Owing to the sudden jumps in prices during the last few weeks, consumers have spent time trying to find 16.25-cent copper, but are now paying 16.37½ cents freely, with some producers refusing such bids and demanding 16.50 cents. The price trend apparently is still upward. In fact, with most of the unsold copper available for shipment earlier than May in the hands of two or three agencies, there is considerable talk that the price will go above 17 cents a pound, delivered. Iron and steel scrap soared during the past week. Whereas a normal price rise is 25 cents a ton, the list moved up on an average of $1 a ton.

NEW YORK METAL MARKET PRICES

| | Feb. 20, 1923 Cents per Pound | Feb. 27, 1923 Cents per Pound |
|---|---|---|
| Copper | | |
| Electrolytic | 15.12½ | 16.37½ |
| Lead, Am. S. & R. price | 8.00 | 8.00 |
| Antimony | 7.50 | 7.50 |
| Nickel, ingot | 30.00 | 30.00 |
| Zinc, spot | 7.05 | 7.20 |
| Tin Straits | 40.00 | 43.12½ |
| Aluminum, 98 to 99 per cent | 23.00 | 24.00 |

### Copper and Brass Products

Copper, brass and bronze mills quote the following prices on brass and copper products:

Copper wire, prices upon application, mill; brass wire, 20.87½ to 22.50 cents; copper sheets, 23.75 cents; copper rods, 21 cents; brass rods, 18.62½ to 22.75 cents; sheet brass, 20.37½ to 22 cents.

## Rocky Mountain Credits Better

Credit conditions in the Rocky Mountain region are improving, according to recent reports from Denver. Bankers in many of the small towns have taken a more liberal attitude in making loans. Electrical accounts in those places are with few exceptions considered good, although there is still a tendency by many contractors to pass their respon sibilities along. The situation in th retail trade is improving.

No failures have been reported sinc the first of the year. Time payment on heavier appliances are being readil financed. Excepting in the dry lan agricultural regions, electrical busines is gaining through the amount of ne building now under way.

# The Week in Trade

**Prices When Quoted Are Those Reported at the Opening of Business on Monday of This Week for Points West of the Mississippi River and on Tuesday for All Eastern Points**

RISING prices in the copper market have caused considerable increases i the price of all wires, including some wiring devices. Shortages of ste in the East are said to be hindering manufacturers of heavier commoditie and deliveries are lengthened as a result. Appliances generally are sellin steadily, and a slight spurt in heaters is still in evidence because of the colde and damper days of the last few weeks. Lamp sales are picking up graduall and increased activity leading to larger volumes than for the correspondin period a year ago is expected by the jobbers. Collections throughout the countr are improving.

**Boston** Greater activity in trade appears to be stimulating all lines. Many New England factories are now working on close to a war-time basis of production, although night operation is not yet general. Slow delivery of materials produced outside this section is the chief handicap to current business. Stocks are very low in steel products extensively used in electrical construction. Appliance sales are holding up well and much interest is evident in illumination. The labor situation here is relatively quiet at the moment. Interconnection of power systems is making rapid headway and there will be considerable construction activity in the transmission field this spring. Additional central-station capacity is being developed in various quarters. The general price trend is firm, but, notwithstanding shortages of some radio apparatus, prices in the retail field are weak.

**New York** Increased activities in manufacturing circles are reported in anticipation of unusually heavy buying during the summer and fall months. Steel-product deliveries are slower than a few months ago, and some manufacturers report that they are hard pressed in filling special orders. The higher copper prices have caused several markings up during the past week on wire, armored cable and some wiring devices. Most jobbers report that lamps are moving in larger volume, and this tendency is expected to increase greatly during the next two months. Conduit stocks continue to remain in a very low condition. Collections throughout the state are somewhat improved.

**Baltimore** Lamps are showing a falling off in considerable volume. The stocks to a large extent are very low. Considerable increase is noted in heaters and heating appliances in the past week, due t the coldest spell of the winter, but this probably only momentary as the mode ation of the weather has already cause a practical halt on this demand. Co ditions in general are marking time, ar jobbers are preparing for the expecte rush of business with the opening of th spring season. Construction work ha been retarded considerably in the pa week owing to weather conditions. I terest is being taken in the comir "Better Homes Exhibition," at whi all the jobbers will be represented wi exhibits.

**Pittsburgh** Jobbers and manufa turers' representativ in this territory are reporting increas sales. This especially applies to ste commodities, such as armored cab conduit boxes and fittings, and ste conduit, which includes various sizes rubber-covered wires. Dealers repo steady demand on appliances with go business on small construction jobs a repair work. The increased prices conduit have not up to the prese affected business to any considera extent.

**Atlanta** The general tendency of t electrical trade is towa greater volume in almost every li with conduit especially in heavy c mand. The construction of office bui ings and large apartments is cutti heavily into the stocks of jobbers, w the result that great difficulty is e perienced in maintaining stocks. Th shortage is general throughout the te ritory, and the price continues climb. Jobbers and manufacturers electrical generating equipment such is required for small municipalities port business in this line the best several years, with the prospects ceedingly bright for the spring a summer trade. Motor sales are

proximately 15 per cent in excess of those of the same period of last year, with the outlook for improvement within the next ninety days. Stocks have been maintained with fair satisfaction, although shipments are lengthening, quotations now being on the average of ten weeks.

## St. Louis

Business reports indicate that sales are remaining unusually good for this time of year in almost all lines. Retail trade has slackened to some extent owing to the cold weather. One of the light and power companies has announced plans for an extensive house-wiring campaign which will undoubtedly result in large sales of all materials used in this line of work, including fixtures and wall switches. The demand for radio equipment continues, stocks being spotty. Many of the industrial plants and the railroads are planning extensive electrical installations in the near future. Jobbers report a slight increase in price for alternating-current generating equipment.

## Chicago

With building construction for the first two months of 1923 averaging an increase of 100 per cent over the same period in 1922, the local demand for wiring material and devices is continuing briskly. Jobbers report increased activity in almost all staple lines. Prices are also stiffening, but there is a tendency to give more effort to obtaining deliveries than to worrying over prices. Winter trade in lamps is active. Radio equipment is selling well and supplies are fairly normal. The motor market is steadily advancing, the biggest volume being on motors ranging from 1 hp. to 10 hp., to be built into machine tools.

## Cleveland

Deliveries are greatly improved and stocks with but a few exceptions are recovered. A rising copper market has tended to make wire quotations higher, but no actual shortage is evident. Conduit is active and the supply is barely sufficient to allow quotations for future deliveries. Industrial equipment sales are in good volume, the week having brought a better movement in transformers, poles and pole-line hardware

Motors are not so active, although prices are firm, but high-tension equipment and porcelain are in better demand. Radio manufacturers have increased production and dealers are ordering consistently. Central-station business continues to improve.

**St. Paul-Minneapolis** Builders predict a banner year. The week's orders are reported smaller. Conduit supply is critical, and retail sales in the city are poor. Wiring is falling off slightly. Prices are firm but uncertain. All steel products show an upward tendency.

**New Orleans** With the approach of summer the electrical trade is already beginning to feel the slump in radio. New Orleans is one of the worst radio markets in the country because of the climate. The fact that there are no first-class broadcasting stations here makes the situation worse. With the lengthening days the market for electric bulbs is falling off. The difference in the consumption between summer and winter is about 25 per cent. Business in washing machines and suction cleaners is just hanging on. New Orleans is a very poor market for apparatus of this kind, principally because New Orleans women as a rule do not do their own housework and find it does not pay to intrust expensive apparatus of this kind to ignorant labor. A number of firms that made a specialty of washing machines and suction cleaners have gone out of business or changed their lines, and apparatus of this kind is now carried as a by-line only.

**Denver** Outside construction throughout the state is being held up by the weather. Local jobbers feel that the lull will permit replenishment of low stocks in certain lines, notably armored cable, conduit, rectifiers and special radio outfits. New orders placed by central stations throughout this territory for generating equipment indicate active market shortly for transmission materials. Considerable interest is developing in ornamental street-lighting systems, especially in the southern part of the state.

**Portland-Seattle** There has been a marked increase in inquiries regarding high-tension equipment during the past week, and the indications are that a considerable amount of this equipment will be installed throughout the Northwest this coming season. Many orders are reported for pole-line material. Bare copper wire is in active demand and the price trend is upward. The base rate advanced from 17½ cents to 18 cents per pound during the past week. The jobbing business continues to remain steady and better than a year ago. Competition is still keen in the contracting field, but there is a plentiful supply of large-sized contracts, and standard contractors generally are busy. Sales are slow for electrical dealers, with the exception of radio material, which is very active.

**San Francisco** With the apparent end of the rainy season building has considerably increased, many sizable staple orders being reported. Retail trade in small appliances and supplies is noticeably better, while larger appliances, especially vacuum cleaners and sewing machines, are moving briskly. Time payment collections are in a slightly better condition than they were last year. Very few stock shortages have been reported during the winter. Rail service has been practically uninterrupted. Temporary shortages, such as in boxes and covers, caused by factory conditions are no longer serious. The demand for these is large and steady.

# Activities of the Trade

Devoted to News of the
Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

## Western Electric Sales Expected to Break Previous Records

Sales by the Western Electric Company for the year of 1923, it is officially predicted, will again break all records. The increase in production, based on orders now on the books, will amount to between 15 and 20 per cent over 1922. Sales for 1922 amounted to $210,900,000, surpassing the year 1920, the previous banner year, by $4,800,000.

Business during the last quarter of 1922 swept away all previous records. Orders received during that period aggregated $63,000,000, or about $5,000,000 more than sales for the same period in 1921.

At the close of business Dec. 31, 1922, there were $62,000,000 worth of unfilled orders on hand. A reflection of this kind of business shows itself in the Hawthorne apparatus schedules for 1923, which are now being prepared. In some cases these schedules have almost doubled and in all cases they have been materially increased.

## Uehling Instrument Orders

Among very recent notable sales of Uehling $CO_2$ recording and indicating equipment are eight units for the Detroit Edison Company, making a total of sixty-five units purchased for the different plants of that company since 1911.

The River Rouge plant of the Ford Motor Company has also added two more units to its present Uehling equipment. This company has now a total of twenty-one units in operation. The application of this equipment to the River Rouge plant is of particular importance since the boilers are of unprecedentedly large size.

## Organize New Jobbing Concern in Binghamton, N. Y.

Edwin C. Wehle, William H. Hecox and Harry A. Yetter are the directors of a jobbing concern known as the Southern New York Electrical Supply Corporation, 78 State Street, Binghamton, N. Y., which has been incorporated for $50,000. The corporation will have floor space of 10,000 sq.ft. Mr. Wehle recently resigned as president of the Southern Tier Electrical Supply Company of the same city and disposed of his interests in that concern in order to devote his entire time to the new supply company.

## To Auction National Conduit Brass Plant March 9

Because the present scope of manufacturing operations of the National Conduit & Cable Company, Inc., under Receiver Clarence G. Galston, does not include the milling of sheet brass, the North plant of the Hastings-on-Hudson concern will be offered at receiver's auction sale, Friday, March 9, on the premises.

"This sale of the North (brass) plant of the National Conduit & Cable Company, Inc., will not affect the copper and cable plants of the company. Operations in these mills during receivership have been profitable and will be continued," declared Receiver Galston.

The North plant comprises ten acres, docks, buildings and equipment. The plant is served by a New York Central Railroad siding and has 1,400 ft. of deep-water bulkhead on the Hudson River. In all, there are fifteen brick and frame buildings, containing about 180,330 sq.ft. of floor space, fitted out with sprinkler system. In the material are five 3-ton traveling cranes.

## Stevens & Wood, Inc., Acquire Wood Hulse Yates Company

Stevens & Wood, Inc., 120 Broadway, New York City, announce that the engineering and construction business formerly conducted by the Wood Hulse Yates Company, Inc., has been acquired with increased personnel. A general engineering and construction business will be conducted. Engineers will give personal attention to all engineering and construction work, including investigations, reports, appraisals, designs, purchase of materials and equipment for steam and hydro-electric power developments, transmission projects, railroad electrification, terminals and shop facilities, port and harbor works and industrial plants, and will supervise the financing, operation and management of utility and industrial properties.

### Standard Electric Time Plans to Spend $65,000 on New Buildings

The Standard Electric Time Company, Springfield, Mass., plans additions to its plant in order to meet increased orders and also to provide facilities for introducing a new adaptation of its product. The buildings, for which about $65,000 will be expended, will include a wing for manufacturing, three stories in height, 88 ft. x 40 ft.; a one-story shipping room, 46 ft. x 46 ft., and a lumber storage shed, 21 ft. x 51 ft. Work will begin immediately. Orders are running one-third ahead of a year ago, officials of the company state.

### Inland Glass Starts Production

The Inland Glass Company, 6101 West Sixty-fifth Street, Chicago, is a new manufacturing concern recently organized to manufacture a complete line of illuminating glassware for domestic, store, office, factory and street-lighting purposes. The production capacity of this company, according to officials, is $2,500,000 worth of glassware annually. Ground was broken for the new factory plant on Oct. 1, 1922, and production was started Feb. 19 last. J. B. Weaver, formerly vice-president in charge of production for the Pullman Car Company, is president; Noble B. Judah vice-president, and H. P. Withers secretary and treasurer.

### New Agent for Wakefield Brass

The F. W. Wakefield Brass Company, Vermilion, Ohio, announces the appointment of the George A. Gray Company, San Francisco and Los Angeles, as its Pacific Coast representative for "Red Spot" hangers and other lighting specialties. Factory stocks will be carried in warehouses at 910 Howard Street, San Francisco, and 236 South San Pedro Street, Los Angeles.

### American Flat Lite Organized to Take Corcoran Properties

The American Flat Lite Company, Cincinnati, has been organized to take over the properties of the T. J. Corcoran Lamp Company and the Corcoran-Victor Company, following the absorption of the latter company by the T. J. Corcoran Lamp Company. The company manufactures automobile and other lamps and has three large plants in Cincinnati. Thomas J. Corcoran is president.

### Westinghouse Bookings Gain 25 per Cent

Bookings of the Westinghouse Electric & Manufacturing Company from Feb. 1 to 15 were 25 per cent ahead of the corresponding period of January. Orders taken were primarily industrial and supply goods with no unusual contracts. January showed the largest bookings of any month with one exception since the beginning of the fiscal year, April 1.

The Westinghouse company is meeting increased demands for power apparatus in mills. The outlook as forecast by the fourteen Westinghouse district sales managers in the United States for the six months from Feb. 1 is very encouraging. Eleven managers looked for increased business in their localities as compared with the previous six months. The forecast on Jan. 1 showed only six of the fourteen expecting larger business for the six months ahead.

### Crescent Insulated Wire & Cable Arranging for Extensions

The Crescent Insulated Wire & Cable Company, Olden and Taylor Streets, Trenton, N. J., is arranging for extensions, to include the production of armored conduit wire, magnet and other wire. The company recently acquired the Crescent Armored Wire Company and will merge the business. A fund of $500,000 has been arranged to carry out the expansion. C. Edward Murry is president of the company.

**The Connecticut Telephone & Electric Company**, Meriden, Conn., manufacturer of radio apparatus, telephones and molded insulation, is planning to erect a new factory building just as soon as weather conditions will permit. It will be built of iron and concrete and will add much space to the company's present extensive plant.

**The A. J. Bressan Company**, 120 Liberty Street, New York City, announces that C. L. Hight, who acted for many years as sales representative and later manager of the New York office for Henry D. Sears, distributor of wiring devices, has associated himself with A. J. Bressan, head of the Bressan company. This company has recently been appointed New York representative for the Adapti Company, Cleveland.

**The Berthold Electrical Manufacturing Company**, Chicago, manufacturer of washing machines, has recently advanced E. L. Bennett from the position of sales manager to vice-president.

**The Bates Expanded Steel Truss Company**, Chicago, Ill., has completed plans for a new galvanized-steel-post plant to cost $100,000. The building will be erected on a site adjoining the present factory and work will be started early in the spring.

**The American Electric Fusion Corporation**, 92 Montana Street, Chicago, has broken ground in the block on Diversey Boulevard between Rockwell and Tallman Streets for a two-story plant, 80 ft. x 130 ft. It is said that this building will be under roof within sixty days and that other units will be completed before the end of the year, which will give this company a total of 60,000 sq.ft. of floor space. It was organized in September, 1920, by E. J. Henke, president, and others.

**The Pure Carbon Company**, Wellsville, N. Y., announces the recent establishment of an Alabama representative, the Commercial Electric Sales Company, 1322 Empire Building, Birmingham, Ala.

**The Electroplax Company**, Toronto, manufacturer of electric supplies, equipment, etc., will soon call for bids for the erection of a plant at Mount Dennis, Ont., to replace the one recently destroyed by fire. H. E. Cory is general manager of the company.

**The Western Instrument Company**, 1001 West Washington Boulevard, Chicago, has acquired a factory on Jefferson Street, south of Munroe Street.

**The Morganthau Electric Company**, 204 Market Street, Harrisburgh, Pa., manufacturer of motors, fans, etc., is planning the erection of a two-story factory, 80 ft. x 110 ft., to cost $90,000, including equipment. R. B. Thompson and L. A. Gable are officials of the company.

**The Combustion Engineering Corporation**, New York City, announces that T. J. Cleary, who recently opened an office in Atlanta for the sale of power plant equipment, has been appointed its Southern agent. Mr. Cleary has been a sales engineer in the South for many years.

**The Moloney Electric Company of Canada, Ltd.**, Toronto, a subsidiary of the Moloney Electric Company, St. Louis, has been incorporated with a capital stock of $500,000 by George D. Y. Leacock, Richard W. Hart and others as provisional directors. It has purchased the tractor building of the Canadian Fairbanks-Morse Company, on Sterling Road, at a cost of $100,000, which will be equipped for the manufacture of transformers, electrical equipment, etc.

**The Dudlo Manufacturing Company**, Fort Wayne, Ind., manufacturer of electric coils, wire, etc., is arranging for the rebuilding of the portion of its enameling department, destroyed by fire Jan. 29. The loss was confined to one of the three buildings at the plant devoted to this service.

**The Delta-Star Electric Company**, 2437 Fulton Street, Chicago, has let a contract for a one-story plant, 103 ft. x 109 ft., to cost $40,000, for the manufacture of high-tension electrical products.

**The Hamilton-Beach Company**, Racine, Wis., manufacturer of electrical equipment, has plans for a three-story addition, 75 ft. x 385 ft., work on which will start about March 1. The investment in building and additional equipment will be approximately $240,000. F. J. Osius is general manager.

**The Tri-City Electric Company**, 16 Mechanic Street, Newark, N. J., jobber and manufacturer of electrical equipment, has leased a five-story building, totaling 30,000 sq.ft., and also a two-story rear structure at 52 Lafayette Street for a new plant. G. M. Ellis is president.

**The New York Testing Laboratories**, 80 Washington Street, New York City, have just installed a new automatic 100,000-lb. Tinius-Olsen testing machine, making their equipment one of the most up to date in New York City for handling tensile tests, compression tests and transverse tests.

## Foreign Trade Notes

CATALOGS OF ELECTRICAL GOODS DESIRED IN CHILE. — C. A. McQueen, American commercial attache, Santiago, Chile, *Commerce Reports* states, is interested in receiving catalogs of electrical goods. The catalogs should be in Spanish if possible and should be sent in duplicate. If local representation has been provided for in Chile, it is suggested that each manufacturer note the name of its local agent.

A COMPANY ORGANIZED IN CHINA TO DEAL IN ELECTRICAL APPARATUS AND TO ENGAGE IN ENGINEERING WORK.—A company has been organized by David L. Anderson, 104 Consular Road, Tientsin, China, to engage in engineering and construction work and also in the merchandising of electrical products. The company proposes to act as agent to manufacturers of power and mining machinery particularly. Mr. Anderson is general manager of the company. Liang Shih Yi, head of a Chinese banking group, is chairman of board of directors.

## Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number.

Purchase is desired in Switzerland (No. 5,511) for electric clippers and other barber supplies.

An agency is desired in Denmark (No. 5,513) for electric motors of all kinds and complete sawmill plants.

An agency and purchase is desired in Japan (No. 5,517) for wireless telephone apparatus and materials, etc.

Purchase is desired in China (No. 5,540) of two electrically driven centrifugal pumps, capable of delivering a minimum of 5,000 gal. of water to tank above main building, against a head of 150 ft., through a 3-in. pipe about 600 ft. long, and two electric motors to drive the above pumps.

Purchase is desired in Bolivia (No. 5,541) of radio-telephone instruments for communications up to 500 miles between cities at altitudes of 300 m. to 4,000 m.; telephones of the magnet system and switches for telephones.

Purchase is desired in Greece (No. 5,543) of power plant and supplies for city lighting, including turbine, regulator and generators.

Purchase is desired in Canada (No. 5,549) of gas producers of 200 hp. to 400 hp. for electric light plant.

An agency is desired in Greece (No. 5,574) for electrical accessories, batteries, generators and Diesel and semi-Diesel generating sets of from 1½ hp. to 40 hp.

The following inquiry has been received by the Philadelphia Commercial Museum, which will furnish names and addresses of the inquirers to any one desiring them and mentioning the number given: Parties in Kyoto, Japan (No. 40,540), would like to get in touch with manufacturers of small electric cars, motorcycles, etc., and would like to receive catalogs and descriptive matter pertaining to same.

## New Apparatus and Publications

ELECTRIC DISHWASHING MACHINE. —The Colt's Patent Fire Arms Manufacturing Company, Hartford, Conn., has placed on the market a new dish, silver and glass washing machine for restaurants, known as model A "Autosan."

ECONOMIZER—Bulletin EC 100 issued by the Power Specialty Company, 111 Broadway, New York City, gives an outline of the use of the "Foster" economizer for recovering waste heat from boiler-flue gases.

LIFTING MAGNETS. — The Cutler-Hammer Manufacturing Company, Milwaukee, is distributing publication No. 3,015 covering the "C-H" lifting magnets. Special attention is called to the "Red" magnets, which are described and illustrated in this booklet.

PORTABLE AIR COMPRESSOR. — A portable air compressor, mounted on a standard Ford truck chassis, has been introduced by the Ingersoll-Rand Drill Company, 11 Broadway, New York City.

PORTABLE VENTILATOR. — The Ilg Electric Ventilating Company, 2850 North Crawford Avenue, Chicago, is distributing a folder describing its new portable "Ilgair" ventilator for household ventilation.

INDUSTRIAL LIGHTING UNIT. — The Ivanhoe-Regent Works of General Electric Company, Cleveland, has developed a new industrial lighting unit, known as "Glassteel." It consists of a white porcelain-enameled steel reflector and a glass-inclosed diffusing bowl.

ASH CONVEYOR. — The Combustion Engineering Corporation, 43 Broad Street, New York City, is distributing a pamphlet entitled "Combusco Ash Conveyor," which describes its "Combusco" water-seal ash conveyor.

SIGNAL EQUIPMENT. — The Signal Engineering & Manufacturing Company, 533 Canal Street, New York City, is distributing a folder describing its signal and control equipment.

SELF-PRIMING PUMPS. — The Fulflo Specialties Company, Blanchester, Ohio, has added a ball-bearing, motor-driven pump of 75 gal. capacity to its line of "Fulflo" self-priming pumps.

INSTRUMENTS FOR RECORDING CONDENSER LEAKAGE. — Bulletin No. 1,222 issued by the Esterline-Angus Company, Indianapolis, Ind., describes its instruments for recording condenser leakage and indicating concentration of boiler water.

FLASHLIGHT.—A new flashlight with a 500-ft. range, known as the "Ever-Ready Focusing Searchlight," has been put on the market by the National Carbon Company, Inc., Thompson Avenue and Orton Street, Long Island City.

TOASTER.—The Terry Kitchen Device Company, 25 West Forty-third Street, New York City, has placed on the market an electric toaster for use in hotels, restaurants, etc.

ELECTRIC STOVES. — The Standard Electric Stove Company, Toledo, Ohio, has issued a catalog supplement and selling price list (twelfth edition) covering its products.

ELECTRIC HAMMER. — The National Electric Manufacturing Company, Inc., Pittsburgh, Pa., is distributing a folder describing its "Syntron" electric hammer.

TRAFFIC-CONTROL DEVICES.—"Trafficons" is the title of a booklet issued by the Line Material Company, South Milwaukee, Wis., describing a new system of traffic-control devices.

PORTABLE REFLECTOR.—A new reflector, known as the portable reflector with extension, has been developed by the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

GEARED UTILITY TOOL.—A new flexible-shaft geared utility tool ("Dumore") has recently been developed by the Wisconsin Electric Company, Racine, Wis.

OUTLET. — A new convenience outlet, known as the "Duplex," is being marketed by the Square D Company, Detroit. This outlet is rated at 10 amp., 250 volts, but the heavy current-carrying parts permit a current of 20 amp. without heating.

ELECTRIC BOILER.—Bastian & Allen, electrical engineers, 58 Haymarket, London, S.W.1, England, is distributing a leaflet describing and illustrating the Bastian & Allen electro-steam boiler.

REFLECTOR.—The Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has developed a new mill-type reflector for use with the new mill-type B lamp in mills and factories.

THEATER LIGHTING.—"The Control of Lighting in Theaters" is the title of bulletin No. 28 issued by the Frank Adam Electric Company, St. Louis, in which an attempt has been made to give some standardized practice for lighting theaters.

## New Incorporations

THE CACAPON ELECTRIC COMPANY, Martinsburg, W. Va., has been incorporated with a capital stock of $11,000 by Clarence E. Martin, Martinsburg; E. L. Coblentz, Frederick, Md., and M. F. Riley, Hagerstown, Md.

THE KIRBYVILLE (TEX.) ICE & LIGHT COMPANY has been granted a charter with a capital stock of $20,000. The incorporators are R. J. Cooper, J. M. Mixon and B. A. Woods.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

GARDINER, ME.—Steps have been taken by the Gardiner Board of Trade for the installation of an ornamental lighting system on Water Street and Depot Square.

RUTLAND, VT.—The city of Rutland has petitioned the State Legislature for permission to amend its character so as to allow the city to operate electric and gas plants.

SPRINGFIELD, VT.—The Vermont Hydro-Electric Corporation will made extensions at its hydro-electric power plant at Carvers Falls.

EAST BRAINTREE, MASS.—The East Braintree Bleacheries, Inc., will build a one-story power house in connection with an extension to its mill.

GLOUCESTER, MASS.—The Gloucester Electric Company will erect an addition to its power plant.

MIDDLEBORO, MASS.—At a recent town meeting the proposal to issue $31,000 in bonds for the construction of a hydro-electric plant at Muttock dam was carried.

WILBRAHAM, MASS.—At a town meeting held recently it was voted to extend the street-lighting system on several additional highways.

EAST GREENWICH, R. I.—Improvement to the street-lighting system on Main Street is under consideration by the Chamber of Commerce.

BETHLEHEM, CONN.—The Litchfield Electric Light & Power Company has begun work on the erection of an electric transmission line to Bethlehem to furnish electrical service here.

BRIDGEPORT, CONN. — The Jenkins Brothers Company will build a switch house for electric service at its valve-manufacturing plant. Motors and other electric power equipment will be installed in the proposed factory addition, to cost about $250,000.

HARTFORD, CONN.—The Connecticut Power Company, controlled by the Hartford Electric Light Company, is planning to erect a high-tension transmission line connecting its electric stations with those of Springfield and Turners Falls. It will also have connection with the hydro-electric plants on the Deerfield and Connecticut Rivers.

## Middle Atlantic States

BATAVIA, N. Y.—In a report submitted to the City Council by Alvord, Burdick & Howson, engineers, changes and improvements to the municipal electric distribution system are recommended, involving an expenditure of about $10,000.

BROOKLYN, N. Y.—Bids will be received by the Bureau of Supplies and Accounts, Navy Department, Washington, D.C., until March 13, for 80,000 ft. of incandescent lamp cord. (Schedule 551.)

BUFFALO, N. Y.—The City Council has adopted a resolution authorizing the gas lamps along Fillmore Avenue for several miles to be replaced with luminous electric arc lamps.

BUFFALO, N. Y.—The Niagara, Lockport & Ontario Power Company has petitioned the Public Service Commission for permission to issue 19,685 shares of stock of no par value, to be sold at not less than $40 per share, the proceeds of at least $407,400 to be used for the purpose of acquiring 916.865 acres of land in the towns of Lewiston and Niagara and in the city of Niagara Falls, owned by the Lower Niagara Power & Water Supply Company.

HADLEY, N. Y.—The electric plant of the Hadley Light & Power Company has been purchased by M. B. Riddle of the Riddle Light & Power Company, Luzerne.

KINGSTON, N. Y.—The installation of a new street-lighting system is under consideration. The Kingston Gas & Electric Company furnishes the street-lighting service.

YONKERS, N. Y.—The installation of a iew street-lighting system in the business listrict is under consideration.

BAYONNE, N. J.—The Ingram-Richardson Manufacturing Company, Beaver Falls, Pa., will build a power house in connection with its proposed local plant, to cost about $85,000.

CAMDEN, N. J.—The Public Service Electric Company has been awarded a con- ract to supply electricity for the new pump- ng stations for the Camden City Water Department. Each pump will have a capac- ty of 1,000 gal. per minute.

CAMDEN, N. J.—Steps have been taken y the Kaighn Avenue Merchants' Asso- iation for the installation of an improved ighting system on that thoroughfare.

EAST ORANGE, N. J.—The City Coun- il is considering the replacement of the as lamps on Main Street, Central, Spring- ale and Fourth Avenues and Harrison and Washington Places with electric lamps. Electric lamps will also be installed in the icinity of the Lackawanna bridges. The ost of the work is estimated at about 100,000.

PATERSON, N. J.—The North Main Street Business Men's Association has peti- ioned the City Council for the installation f about twenty-five additional ornamental amps on North Main Street.

HAZLETON, PA.—The Jeddo-Highland Coal Company plans to rebuild its power ouse at its No. 2 Highland Colliery, recently amaged by fire, with a loss of about 17,000.

PHILADELPHIA, PA.—Bids will be re- eived by the Bureau of Supplies and ccounts, Navy Department, Washington, . C., until March 13 for 25,000 ft. single- onductor high-tension ignition cable. Schedule 553.)

PITTSBURGH, PA.—The Fort Duquesne aundry Company will build a power house t its plant at 129 Fortieth Street.

POTTSVILLE, PA.—An electrically oper- ted pumping plant will be installed in con- ection with a sewage-disposal plant, to ost about $1,000,000.

POTTSVILLE, PA.—The Eastern Penn Electric Company has been organized by the Eastern Pennsylvania Light, Heat & Power Company, Pottsville, as a subsidiary, to onstruct and operate electric generating lants and systems in Schuylkill County.

ABERDEEN, MD.—The Maryland Fin- hing Company will build a power house i connection with its proposed local plant, cost about $30,000.

ANNAPOLIS, MD.—Bids will be taken t once by the Supply Officer, United States avy Department, for 20,000 ft. of cable. Requisition 65.)

HAVRE DE GRACE, MD.—The Havre e Grace Electric Company has issued 90,000 in bonds, part of the proceeds to be sed for extensions and improvements.

BLUEFIELD, W. VA.—The Pond Creek ocahontas Company, recently organized operate coal properties in McDowell ounty, plans to install a power house in onnection with an electrically operated al-mining plant. T. B. Davis is president.

HUBBELL, W. VA.—The Huntington as & Development Company is planning rebuild its power house and lubricating orks, recently damaged by fire. The loss estimated at about $100,000.

LOGAN, W. VA.—The Guyan Machine hops are making inquiries for an electric oist with alternating-current motor; also r a motor-generator set, 100 kw. to 150 v., or a rotary alternator of same capacity.

DANVILLE, VA.—The Danville Traction Power Company has entered into a ten- ar contract with the city of Danville for e purchase of energy from the municipal ectric light plant, the service to begin ly 1. The traction company will install rotary converter in the municipal plant.

NORFOLK, VA.—Plans for the proposed cal sugar refinery to be erected by Adolph gal, Philadelphia, and associates, to cost out $4,000,000, include a power plant. harles B. Hughes, president Hughes-Ellis- owell Corporation, 403 Boush Street, Nor- lk, is interested in the project.

STRASBURG, VA.—The Town Council is awarded the Northern Virginia Power ompany, Winchester, a franchise to fur- sh electricity here.

SUFFOLK, VA.—The Instant Collapsible im Company, Bank of Commerce Building, orfolk, contemplates the construction of substation at its proposed local plant.

WASHINGTON, D. C.—The Potomac ectric Company contemplates the erection an office building and garage at 13½ and Streets, N. W., to cost about $200,000. ne Milburn-Heister Company, 710 Four- enth Street, N. W., is architect.

## North Central States

ALMA, MICH.—The property of the Central Michigan Light & Power Company has been sold to the Consumers' Power Company, Jackson. The Central company supplies electrical service in cities and towns in Clare, Isabella and Gratiot Counties.

DETROIT, MICH.—The Père Marquette Railroad Company plans to install electrical equipment and an addition to its power house in connection with improvements at its shops on Twelfth Street, Detroit, and at Grand Rapids, to cost about $1,200,000 and $1,500,000, respectively. An electric block system from Alexis to Carleton is also under consideration, to cost about $100,000.

JACKSON, MICH.—Plans are being considered by the Commonwealth Power, Railway & Light Company for extensions in Michigan, to cost about $9,000,000. The proposed work includes a 30,000-hp. steam-driven plant on the Saginaw River, between Saginaw and Bay City; a 12,000-hp. hydro-electric development on the Au Sable River at Alcona, and a 20,000-hp. plant on the Manisteo River.

CINCINNATI, OHIO.—Surveys are being made of the electric power requirements of the southern Ohio district by the Union Gas & Electric Company. Tentative plans, it is said, are to erect an electric generating plant in the West Virginia coal fields, to cost about $25,000,000.

CLEVELAND, OHIO.—Bids will be received at the office of the Commissioner of Purchases and Supplies, City Hall, until March 10 for furnishing X-ray equipment for the new city hospital.

CLEVELAND, OHIO.—Plans are being prepared by the Cleveland Electric Illuminating Company for an electric boosting station at North Woodland Road and East 130th Street, to cost about $50,000.

CLEVELAND, OHIO.—The Cleveland (Ohio) Electric Illuminating Company, it is reported, contemplates taking over the power house of the Lake Shore Electric Railroad Company in Avon Beach Park, east of Lorain.

GIRARD, OHIO.—The proposed new street-lighting contract with the Pennsylvania-Ohio Power & Light Company calls for forty-three lamps of 100 cp., 127 lamps of 250 cp. and twelve lamps of 400 cp. At present there are only eighty-seven street lamps in operation.

HURON, OHIO.—The trustees of the municipal electric light plant are negotiating with the Sandusky Gas & Electric Company to furnish electricity in Huron, as the municipal plant is not self-sustaining.

PORT CLINTON, OHIO.—The American Gypsum Company will install electric power equipment in connection with its proposed plant addition, to cost about $100,000.

SOUTH BEND, IND.—Plans are being considered for replacing the sixty-four gas lamps now in use in River Park with electric lamps at the expiration of the present contract, which expires April 30.

SOUTH BEND, IND.—Work will soon begin on the erection of a power plant, in connection with a new five-story hospital to be erected at 123 West Navarra Street, by the Methodist Hospital Association. Schmidt, Garden & Martin, 104 South Michigan Avenue, Chicago, are architects.

CHICAGO, ILL.—Upon the rejection of the third bid for the installation of 14,000 municipal electric street lamps, George E. Carlson, Commissioner of Gas and Electricity, has announced that the city will install the lamps.

KEWANEE, ILL.—The Consolidated Light & Power Company has submitted a proposal to the City Council offering to sell its plant to the city. Bonds to the amount of $125,000 have been voted for the installation of a municipal electric plant.

MILWAUKEE, WIS.—The Milwaukee-Western Electric Railway Company, 253 Third Street, contemplates the construction of a new electric railway to Fox Point, via Juneau, Beaver Dam, and other towns, 65 miles long, to cost about $1,500,000.

MILWAUKEE, WIS.—The Milwaukee Electric Railway & Light Company has petitioned the Wisconsin Railroad Commission for permission to issue $3,000,000 in capital stock, the proceeds to be used for extensions to its electric light and power and street-railway service in Milwaukee and surrounding territory, including Whitefish Bay, Shorewood, North Milwaukee, Wauwatosa, West Allis, Cudahy and other towns.

OSHKOSH, WIS.—Plans have been prepared by the Water Department for additions to the waterworks pumping station, including the installation of three electrically operated pumps, to cost about $80,000.

SLAYTON, MINN.—Arrangements have been made by the Northwest Light & Power Company, Hutchison, to extend its transmission line from Pipestone to Slayton.

CEDAR RAPIDS, IOWA.—The Disbrow Sash & Door Company, Seventh Avenue, contemplates the erection of a power house, in connection with an addition to its plant to cost $80,000.

DUBUQUE, IOWA.—The Albert Emanuel Company, Inc., 61 Broadway, New York, has acquired the property of the Dubuque Electric Company and the Eastern Iowa Electric Company. Tentative plans are under consideration for extensions and improvements.

EAGLE GROVE, IOWA.—Electric power equipment will be installed in the proposed local ice-manufacturing plant, to be erected by the Iowa Cold Storage Company, Gilmere, to cost about $50,000.

OSKALOOSA, IOWA.—All work in connection with the proposed hydro-electric plant to be erected at Harvey by the city of Oskaloosa, we are informed, is in charge of Brown & Cook, Ottumwa, engineers. This is to correct an item published Jan. 27 stating that Burns & McDonnel, Interstate Building, Kansas City, Mo., were engineers.

SIOUX CITY, IOWA.—The Sioux City Brick & Tile Company, Third Street, will install electric power equipment in connection with the rebuilding of the portion of its plant recently damaged by fire. The loss is estimated at about $50,000.

KIRKSVILLE, MO.—The City Council has authorized a bond issue for $40,000 for extensions and improvements to the municipal electric plant. Black & Veatch, Mutual Building, Kansas City, Mo., are engineers.

SEDALIA, MO.—The West Missouri Power Company has issued $1,350,000 in bonds, part of the proceeds to be used for extensions and improvements.

SENECA, MO.—At an election to be held April 23 the proposal to issue $25,000 in light and power bonds will be submitted to the voters.

HOT SPRINGS, S. D.—Preparations are now being made for the installation of a new power plant at Sylvan Lake to replace the plant which was destroyed by fire last summer. The size of the plant depends upon the amount appropriated by the Legislature for state park requirements.

LINCOLN, NEB.—The Continental Gas & Electric Corporation has disposed of a bond issue of $2,000,000, part of the proceeds to be used for extensions and improvements to the system of the Lincoln Gas & Electric Company, recently acquired.

ONG, NEB.—The Electric Development Company, Omaha Loan & Building Association Building, Omaha, is planning to erect a transmission line to Ong, Shickley and vicinity, to cost about $28,000. Distributing systems will also be installed.

## Southern States

BELMONT, N. C.—The Stowe Spinning Company contemplates extensions to its works, including the construction of a power house, to cost about $750,000.

BURGAW, N. C.—Bonds to the amount of $12,000 have been issued for the installation of an electric lighting and power system.

NORTH WILKESBORO, N. C.—The Wilkes Hosiery Mills Company plans to build a power house in connection with its proposed local mill, to cost about $75,000.

PINE BLUFF, N. C.—Electrically driven pumping machinery will be installed in connection with extensions and improvements to the waterworks system. Bids, it is understood, will soon be asked for equipment.

RALEIGH, N. C.—The Carolina Power & Light Company contemplates enlarging its substations at Goldsboro, Selma and at several other places.

ROCKINGHAM, N. C.—Plans for the proposed new textile mill to be erected by the Leak Manufacturing Company, at a cost of about $500,000, provide for an electric power plant.

TAYLOR, S. C.—A steam-driven electric generating plant of 1,000 kw. capacity, will be erected at the proposed new mill of the Southern Bleachery Company. J. E. Sirrine & Company, Greenville, S. C., are architects and engineers.

ATLANTA, GA.—The George Railway & Power Company contemplates the erection of a susbtation on Walton Street.

MACON, GA.—Electric power equipment will be installed in the proposed ice-manufacturing and cold-storage plant to be erected by the Central Railway of Georgia, Savannah, to cost about $300,000.

ST. PETERSBURG, FLA.—The St. Petersburg Lighting Company contemplates extension and improvements to its system.

TALLAHASSEE, FLA.—The installation of an ornamental lighting system on Park Avenue, between Duval and Calhoun Streets is under consideration.

CHATTANOOGA, TENN.—The Southern Sheet Steel Company will build a power house in connection with its proposed new plant, near Glendale, to cost about $1,000,000.

LIVINGSTON, TENN.—The Cumberland Power Company contemplates extensions and improvements in the local electric system, recently acquired.

PIKEVILLE, TENN.—The Pocahontas & Sewanee Coal & Iron Company will install electric power equipment at its properties. The Williamson Construction Company, Pikeville, will make purchases.

LEEDS, ALA.—Preparations are being made by the Alabama Power Company, Birmingham, to erect a substation in Leeds, to cost about $1,000,000.

CLINTON, MISS.—Negotiations are under way between the Town Council and the Jackson (Miss.) Public Service Company whereby the latter may furnish electricity to operate the local system. If the project is carried through a twenty-four-hour service will be established.

MOSS POINT, MISS. — The Southern Paper Company will soon break ground for the construction of a power plant in connection with mill extensions, to cost $1,500,000.

NEW ALBANY, MISS.—Bonds to the amount of $25,000 have been issued for extensions and improvements to the municipal electric plant.

HOT SPRINGS, ARK.—Permission has been granted to the Caddo River Power & Irrigation Company to construct a hydro-electric project on the Caddo River, to cost about $5,000,000. The initial installation will develop about 15,000 hp. and will cost about $2,000,000.

DE QUINCY, LA.—Bids will be received by W. W. Tuck, president of the municipal waterworks, light and power board, until March 6 for construction of a municipal electric light plant and waterworks system. The equipment will include one 50-kw. and one 100-kw., three-phase, 50-cycle, 2,300-volt generator directly connected to oil engines, switchboard, motor-driven well pump, electric light and power distributing system, meters, transformers, etc. J. W. Billingsley, Interstate Bank Building, New Orleans, is consulting engineer.

ARDMORE, OKLA. — The Consumers' Light & Power Company will build a power plant to cost about $100,000. A cold-storage plant will also be erected.

CLINTON, OKLA.—At an election held recently the proposal to issue $45,000 in bonds for extensions to the municipal electric light plant and waterworks system was defeated. A new election will be held later.

CUSHING, OKLA.—The local plant of the Minnesota Electric Light & Power Company, Bemidji, Minn., was recently destroyed by fire, causing a loss of about $50,000. The plant, it is stated, will be rebuilt at once.

WYNNEWOOD, OKLA. — Bonds to the amount of $85,000 have been voted for extensions to the municipal electric light plant and waterworks system.

ABILENE, TEX.—The West Texas Utilities Company contemplates extending its transmission lines from Rotan to Roby.

BEAUMONT, TEX.—Arrangements are being made by the Eastern Texas Electric Company for extensions and improvements to its system, to cost about $150,000.

CUERO, TEX.—The Texas Central Power Company is planning to extend its high-tension transmission line to Kingsville and to furnish electrical service there.

HEMPHILL, TEX.—Plans are under way for rebuilding the electric light and power plant of the Temple Lumber Company, recently destroyed by fire. The loss is estimated at about $150,000.

HENRIETTA, TEX.—The City Council has entered into a contract with the Wichita (Tex.) Electric Company for the installation of seventy street lamps. In the business district 400-cp. lamps will be used and in the residential section 50 cp. will be installed.

VERNON, TEX.—The Texas Electric & Ice Company is preparing plans for the construction of an electrically operated ice-manufacturing plant in Vernon. Plants will be built at Bay City and Mount Pleasant.

VERNON, TEX.—The Vernon Electric & Ice Company has submitted a proposal to the City Commission offering to take over and operate the municipal waterworks and street-lighting systems. The city has authorized a bond issue of $100,000 for the installation of a municipal lighting system, but the project is tied up in litigation.

## Pacific and Mountain States

OLYMPIA, WASH. — The proposal to extend the ornamental lighting system to take in Franklin Street and the cross streets from Fourth to Sixth Street has been approved by the City Council.

TACOMA, WASH.—The Wheeler-Osgood Company will install electric power equipment at its proposed new sash and door plant, to cost about $250,000.

YAKIMA, WASH.—The installation of an ornamental lighting system on Yakima Avenue from the railroad tracks to Twelfth Avenue is under consideration. The cost is estimated at about $8,000.

EUREKA, CAL.—Plans are under consideration for the installation of an ornamental lighting system in Seventh Street. H. H. Hannah is city engineer.

MARYSVILLE, CAL.—Plans are being considered for the installation of an ornamental lighting system in Fourth and Fifth Streets. W. M. Meek is city engineer.

SAN FRANCISCO, CAL.—Extensions are contemplated by the Market Street Railway Company, including a double-track line from Pacific City to San Mateo, to cost $150,000; double-track line from San Mateo to Beresford, $355,000, and the erection of substation, $30,000.

SAN PEDRO, CAL. — Plans are being prepared by the Pacific Coast Borax Company for an addition to its borax-refining plant, including machine shop, boiler house and generating plant, to cost about $75,000. A. C. Martin, Higgins Building, Los Angeles, is architect.

TURLOCK, CAL.—The Board of Trustees has granted the Turlock Irrigation District permission to install a distribution system to supply electricity for lamps and motors in the city.

WILLITS, CAL.—The Central Mendocino County Power Company will soon ask for bids for the erection of a transmission line to Potter Valley, 15 miles, to connect with the plant of the Mountain Water & Power Company. H. S. Tittle, 766 Folsom Street, San Francisco, is electrical engineer.

CALHAN, COL.—Plans have been prepared for a municipal electric plant and waterworks system, to cost about $50,000. The Brew & Sidow Engineering Company, Kitridge Building, Denver, is engineer.

DENVER, COL.—The City Council has adopted an ordinance permitting the Denver Gas & Electric Light Company to substitute Mazda lamps for street lighting for the arc lamps now in use.

FORT MORGAN, COL.—Work will soon begin on the construction of a new municipal electric plant.

TUCSON, ARIZ.—The Tucson Gas, Electric Light & Power Company contemplates extensions and improvements to its power plant and system, to cost about $300,000

## Canada

POWELL RIVER, B. C.—Tenders are being asked on the first unit of a power plant to be erected at Power River for the Powell River Company, Ltd., Vancouver. Tenders will be received by N. R. Lang, manager, for a power house and smoke stack.

WINNIPEG, MAN.—Tenders will be received by the city clerk until March 15 for water-tube boilers and accessories.

MONKTON, ONT.—The Council is considering the installation of a hydro-electric plant and system.

NORWICH, ONT.—Bonds to the amount of $25,000 have been voted for the installation of an electric lighting and power system.

BAGOTVILLE, QUE.—Tenders, it is reported, will soon be asked by the Town Council for the construction of a municipal power plant to cost about $150,000.

DRUMMONDVILLE, QUE.—The Southern Canada Power Company, Montreal, is considering a 30,000-hp. hydro-electric development at Hemming's Falls on the St. Francis River, near Drummondville, this year.

MONTREAL, QUE.—Work has started on a hydro-electric development, to cost about $7,000,000, at St. Etienne des Gras, Quebec, for the Shawinigan Water & Power Company.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued Feb. 6, 1923)

1,445,206. THERMIONIC RECTIFIER AND C[IR]CUITS THEREFOR; J. K. Elderkin, Newa[rk], N. J. App. filed July 8, 1921. Stora[ge] battery charging apparatus.

1,445,217. WINDING DEVICE FOR DR[OP] LIGHTS; C. V. Johnson, San Francis[co], Cal. App. filed Sept. 25, 1918. Automa[tic] coil winder for extension or trou[ble] lights.

1,445,226. SEMI-AUTOMATIC TELEGRAP[H] SENDING MACHINE; H. G. Martin, Broo[k]lyn, N. Y. App. filed Dec. 10, 19[..]. Simplified construction of the operat[ing] lever.

1,445,231. WELDING JIG; O. Muller, [..] Ridgewood, N. Y. App. filed Sept. [..] 1919. For welding vacuum-tube el[ec]trodes.

1,445,233. TELEGRAPH SYSTEM; H. [..] O'Neill, Brooklyn, N. Y. App. filed N[ov.] 19, 1919. Improves wave-form impul[ses] transmitted over conductors having h[igh] electrostatic capacity.

1,445,235. IMPULSE TRANSMITTING DEVI[CE]; L. D. Plotner, Brooklyn, N. Y. App. fi[led] April 14, 1920. For use at an operato[r's] position in semi-automatic telephone s[ys]tem.

1,445,242. VARIABLE INDUCTANCE ELEME[NT]; W. J. Shackelton, Scotch Plains, N. [J.] App. filed Dec. 24, 1920. Coils wound [in] form such that inductance varies p[ro]portional to angle turned through.

1,445,258. TESTING SYSTEM; S. B. Willia[ms], Jr., Brooklyn, N. Y., and H. L. Bosta[..], West New York, N. J. App. filed Feb. [..] 1919. Testing device for telephone ap[pa]ratus.

1,445,260. METHOD OF AND APPARATUS [FOR] TESTING ELECTRICAL COILS; A. H. Ada[..], Sparkill, N. Y. App. filed Oct. 23, 19[..]. Detects short-circuited coil during wi[nd]ing operation.

1,445,278. THERMIONIC VACUUM TUBE; [..] A. Heising, East Orange, N. J. App. fi[led] Nov. 1, 1917. Series arrangement [of] filaments of several tubes.

1,445,321. RHEOSTAT; A. A. Kent, Ardm[ore], Pa. App. filed July 21, 1922. For va[ry]ing filament current in vacuum tubes.

1,445,360. ELECTRIC TROLLEY APPARAT[US]; E. Schild, Seattle, Wash. App. filed [..] 31, 1921. Trackless trolley pole.

1,445,391. SLIDING-TROLLEY SHOE; H. [..] Coats, Veedersburg, Ind. App. filed [..] 24, 1922. Reversible flat surface.

1,445,398. INCANDESCENT ELECTRIC LA[MP]; K. Kambayashi, Kuze-Gun, Kyoto, Ja[pan]. App. filed April 29, 1921. Protects [fila]ment and lead wires from injurious ef[fect] of Edison effect current.

1,445,411. PROCESS OF MAKING VAL[VES]; C. Pfanstiehl, Highland Park, Ill. [App.] filed Dec. 26, 1916. Welding two pi[eces] of metal of different melting points.

1,445,421. TELAUTOGRAPHIC SYSTEM; G. [..] Tiffany, Summit, N. J. App. filed [..] 25, 1916. Telautographic and teleph[oni]c messages simultaneously transmitted [over] the same line.

1,445,422. VARIABLE INDUCTANCE; E. [..] Turney, Holmes, N. Y. App. filed M[arc]h 22, 1921. Hinged coils.

1,445,432. TELEPHONE-EXCHANGE SYST[EM]; B. G. Dunham, Hawthorne, N. J. [App.] filed Aug. 7, 1919. Decreases time inte[rval] between actual seizure of trunk and ap[pli]cation of busy connection.

1,445,501. HOT-WATER BAG; H. F. Dwi[..], Highland Mills, N. Y. App. filed July [..] 1921. Electrically heated.

1,445,503. GALVANIC BATTERY; G. F[..] L. Fuller and G. J. A. Fuller, Lon[don], England. App. filed Feb. 16, 1921. [..] action prevented until it is required [for] use.

1,445,529. ELECTRIC LOCK AND ALARM [FOR] AUTOMOBILES; S. L. Mathews, St. L[oui]s, Mo. App. filed Oct. 11, 1919. Mec[han]ically controlled automatic clutch [and] electrical locking and circuit-making-[and-]breaking mechanism.

1,445,567. BATTERY-CHARGING CONNEC[TOR]; M. D. Sweet, Alliance, Ohio. App. [filed] May 26, 1921.

1,445,580. AUTOMATIC SYSTEM OF [CON]TROLLING THE CHARGING OF STORAGE [BAT]TERIES; O. P. Fritchle, Denver, Col. [App.] filed March 1, 1920. Gives a direct [indi]cation of the amount of charge that [in] battery.

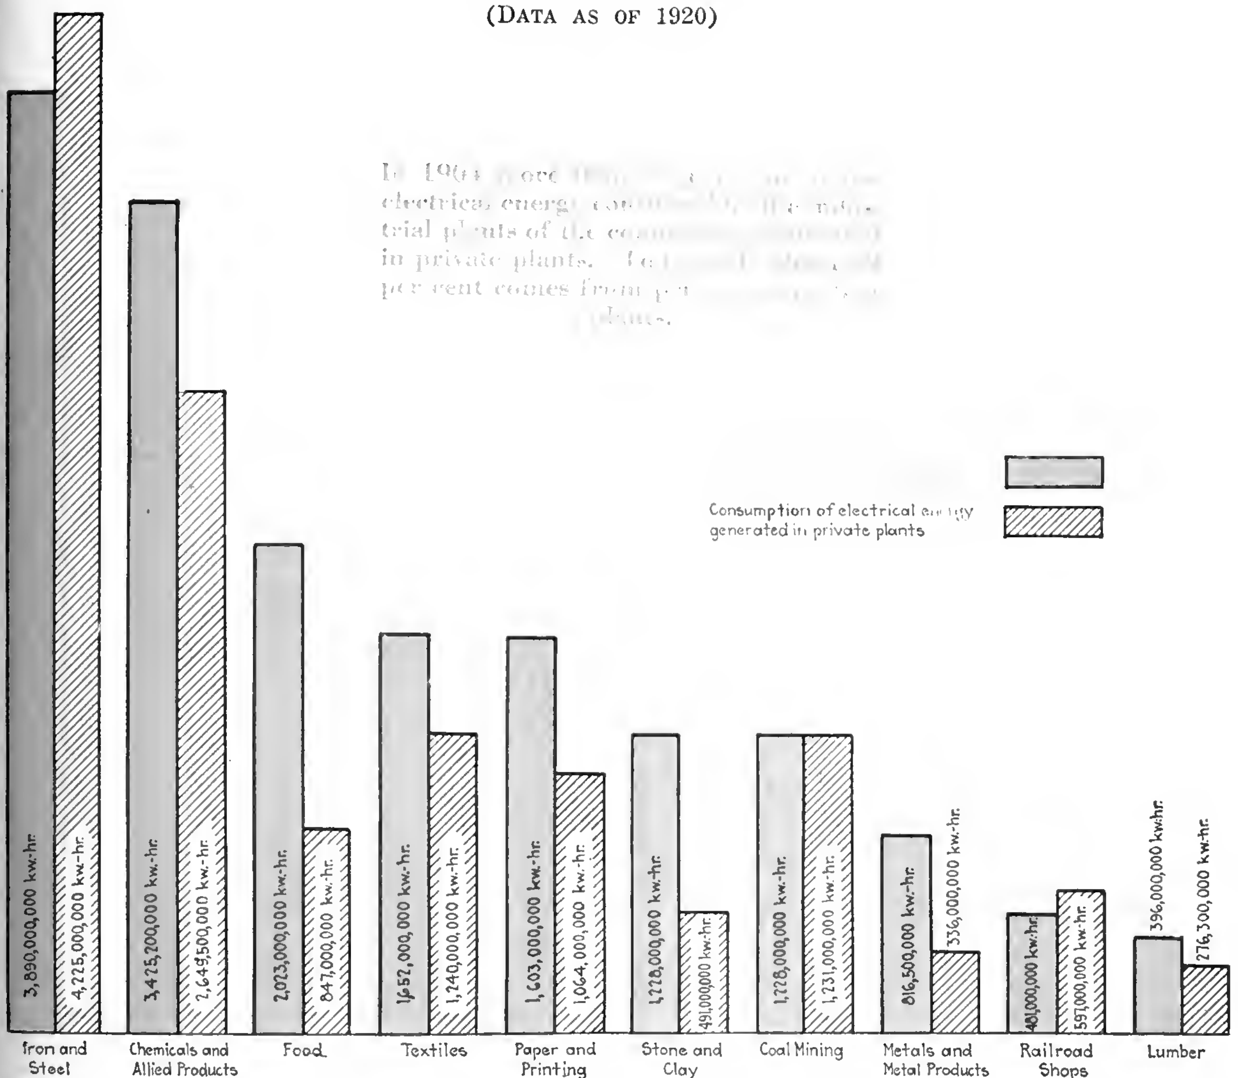
1,445,585. STREET INDICATOR; W. G[..], Wichita, Kan. App. filed Jan. 8, [..]. Indicates next stop of vehicle.

# Business Facts for Electrical Men

Selected Statistics Presented Graphically for the Use of All Interested in Analyzing the Trend of the Electrical Business

## The Extent to Which the Central Station Has Supplanted the Private Generating Plant

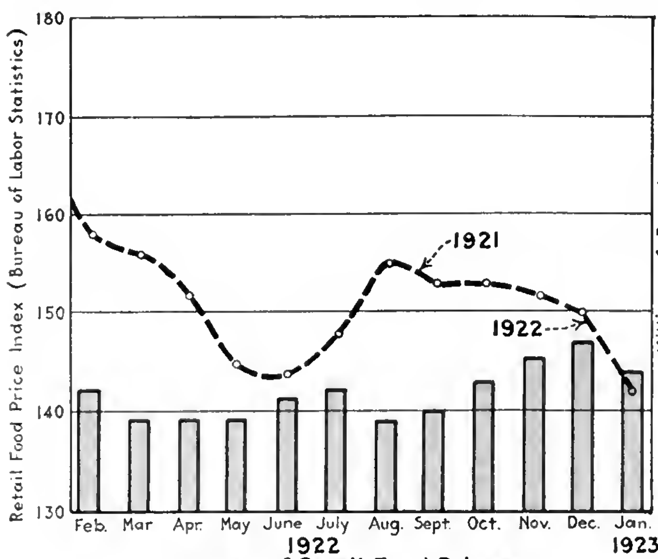
(DATA AS OF 1920)



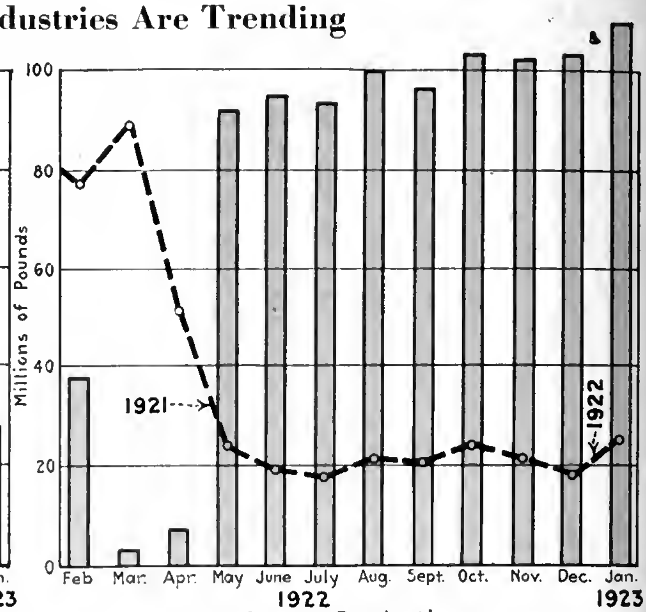
## A Measure of Progress

"ACHIEVEMENT is the measure of progress, the prophecy of greater things." The electric light and power industry during its forty years of history has achieved results unparalleled by any other primary industry and stands today on the threshold of still greater things. The gradual replacement of privately generated power by central-station service brought about by the greater efficiency, lower costs and greater dependability is of itself an achievement worthy of record. In 1904 more than 72 per cent of the electrical energy consumed by the industrial plants of the country was generated in private plants. In 1920 all but three primary industries used more central-station energy than electrical energy from private generating plants, and it is probable that today the central station has overtaken private-plant generation even in these three industries. The progress of the industry is continual.

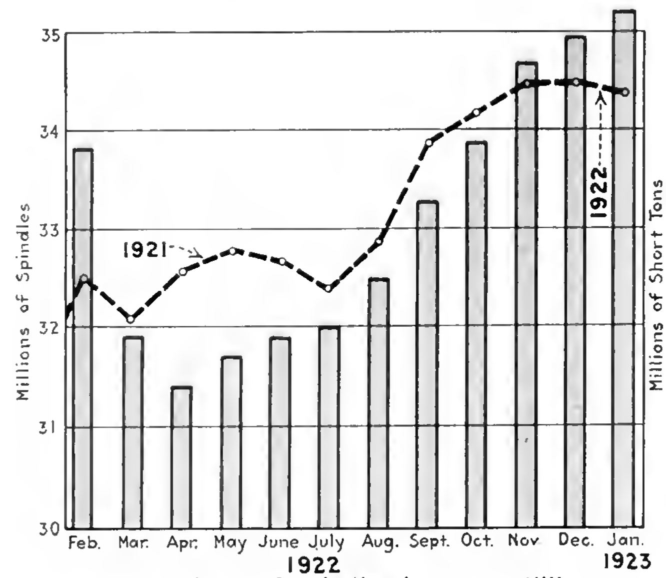
## How the Primary Industries Are Trending



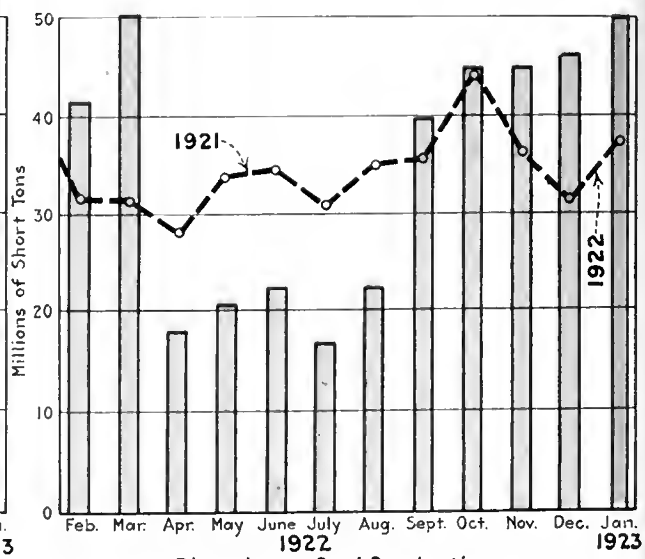
Index of Retail Food Prices



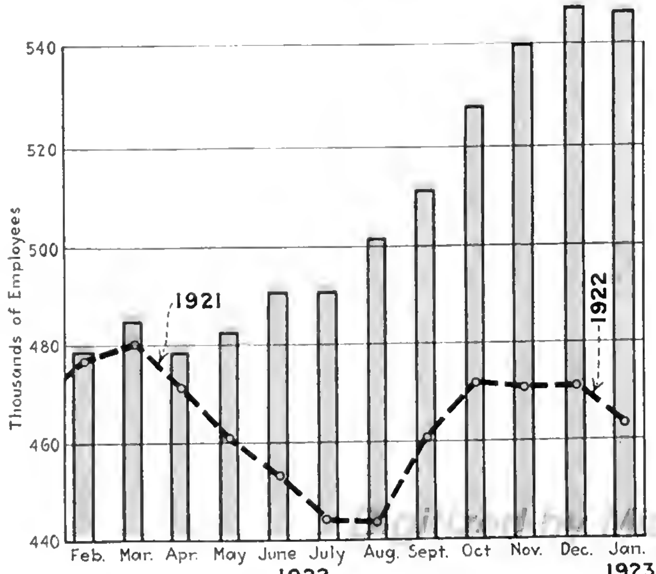
Copper Production



Activity of Spindles in Cotton Mills



Bituminous Coal Production



Employees in Factories of New York State

## Factory Employment Retarded

ALTHOUGH a large increase in general productive activity is indicated by figures received from the Department of Commerce for January, data on employment in factories for the typical industrial state of New York indicate that the high point of employment has been reached, at least temporarily. The number employed during January, however, was still approximately ninety thousand below the high figures reported in March, 1920, so that the slight drop reported for January is probably only a seasonal reaction, which will be overcome as the year advances. The almost uniformly large monthly increases in number of factory employees which have been experienced since last July were bound to taper off as industry caught up with demand, and it is probable that from now on employment will show the ups and downs which are normally characteristic of the various seasons of the year.

# Electricity and Immigration

THE connection between electricity and immigration may seem somewhat nebulous, but it is not at all beyond the bounds of possibility that the electrical industry may prove most effective at least in mitigating, if not in solving, the immigration problem of the country. Electricity has conquered most of the multitudinous tasks which have confronted it; it has gone even further and has been constantly on the alert with untiring and brilliant initiative to devise and create new ways to make life easier and to help material and social progress. Even with this record, the problem of immigration will put the electrical industry on its mettle. Yet if there is any answer to the insistent and growing demand for more cheap hands to perform menial tasks it lies in the further substitution of mechanical appliances and automatic control for human brawn and brain. And electricity is the one agency for motive power and for effective control to make this possible.

IMMIGRATION is a subject which has forced its attention on everyone in this country — whether he is an employer of labor or merely a reader of the daily newspaper. Industry calls for immigrants in large numbers, and the high cost of many things is blamed on the scarcity of low priced men to do the physical work. On the other hand, those who are most concerned over the character of the future American citizens urge more and more restriction on intending immigrants. The recent Congress tried in vain to make some constructive advance on the subject but its efforts came to naught except to incite some intelligent discussion.

Briefly, as previously pointed out in these columns, here is the story: Immigrants came to this country in desirable numbers and character during the latter half of the last century. Their quality decreased and quantity increased the two decades preceding the war. While common labor came in and helped do the common work, finally, as one noted American has put it, some lumps got into the "melting pot" that we have been unable to melt. The present 3 per cent law based on the 1910 ratio of races is admittedly not the solution. To open the gates creates an Americanization problem the answer to which is not known, the result of which might prove disastrous. To adopt a 2 per cent law based on the 1890 ratio of races, it is held, will give the quality but not the quantity. Some answer is needed which will at once retain American institutions and standards and yet not halt American industry and progress.

AS A NATION we have developed machinery to perform many chores. Electricity as a motive power and as a control agency has been the most important factor in the extension of these benefits. But the half has not been realized. For the electrical industry there still exists the greatest opportunity further to develop applications of electricity to do the work of man, or, more effectively perhaps, to multiply the work of the individual. Industry after industry have not even dreamed of what electricity can do to solve their production and labor problems. There is practically no task that electricity can not ultimately perform. But what of the human factor? Once again — it is only the more simple of control operations that electrical equipment now supplies — the beginning has not been much more than made in what can be done to replace the present necessary human brain by selective electrical control apparatus.

Genius rises to meet the demands of the times. The electrical industry will not be slow to recognize and grasp the opportunity of service to the nation in this problem. It must tell the rest of the country of its ability and its plans. More and more will it relieve industry of its labor problems, freeing machine-bound Americans to take the place of foreign importations and to become better paid — because more efficient — men and citizens. In this way will electricity in the hands of American inventive ability continue to prove its inestimable value to humanity and to the nation.

# Farley Osgood

*A prominent engineer and forceful executive who has a particular faculty as an organizer and director of men.*

FEW men can find the time or have the ability or inclination to contribute personally and constructively to many different activities in the electrical industry, and pre-eminence is usually obtained by those who have specialized and concentrated on one particular phase. Farley Osgood is a leader who has established himself as an active worker in many electrical activities and has carried out the letter and spirit of his belief in the benefits to be derived from co-operative work and personal participation in things which advance the interests of the industry. As vice-president and general manager of the Public Service Electric Company of New Jersey, Mr. Osgood directs the engineering and business activities of one of the largest light and power utilities, yet, through his ability in organizing a supporting staff, he finds time to take an active part in the work of the national scientific and public utility organizations.

Mr. Osgood was born in Boston in 1874 and after completing his studies at the Massachusetts Institute of Technology in 1897 he entered the service of the American Telephone & Telegraph Company. He rapidly advanced in this organization to the position of territorial manager in New Jersey. After five years he became chief engineer and general manager of the New Milford Power Company in Connecticut and was very active in working out pioneer engineering problems associated with 33,000-volt transmission. Four years later Mr. Osgood became general superintendent of distribution for the Public Service Electric Company. His ability as an organizer and educator of men brought about rapid advancement until he was directing the production and engineering departments, and in April, 1917, he became vice-president and general manager of the company.

In association work Mr. Osgood has been very active. He was vice-president of the A. I. E. E. in 1914-16 and manager in 1911-14, and he has served as chairman of the New York Section. In the N. E. L. A. he contributed largely to national specifications as chairman of the overhead-line construction committee, and he had much to do with the formulation of the National Electrical Code as a representative of the A. I. E. E. His long-extended and valuable service in association work has seldom been equaled, and the electrical industry is indebted to him in unusual degree for his work and counsel. His personal and social popularity is attested by his membership in many social and sporting clubs in New York and New Jersey.

# Editorial Comment

Electrical World, March 10, 1923
Volume 81 Number 10

## Phenomenal Growth in the East

ORDINARILY in matters electrical it is the West that sets the pace. We are wont to associate the West with things progressive and with engineering of the spectacular or daring sort. Are there records of huge units or exceedingly high potentials to be established, it is almost taken for granted that the West will supply them. But while we admire the enterprise and initiative so often and so freely displayed by our Western friends, we ought not to overlook records being made in the conservative East. For instance, last year the Brooklyn Edison Company added more than 55,000 new customers to its lines and made power contracts aggregating over 60,000 hp.—a huge central-station system in itself. The gross operating revenue during the year increased 18 per cent, while the gain in the net corporate income was approximately 52 per cent.

But that is only part of the story. To keep pace with such a growth requires equipment and new capital, and particularly an organization capable of responding to such large demands. These things, through the foresight of M. S. Sloan and the co-operation of the Bradys, have all been provided. The authorized capital of the company has been increased since 1921 from $19,000,000 to $50,000,000. Work has started on a new and most interesting generating station and a new office building. Lines have been extended right and left, and so great is the demand for service that it is only with difficulty that the company manages to keep from being literally swamped. This desire for electricity has swept over the whole industrial section of the East like a tidal wave. Boston, New York, Philadelphia, Newark, Baltimore, Buffalo, Pittsburgh, Cleveland, Detroit and Chicago have all felt it, so that for some little time to come things will be humming in the eastern part of the country.

## Cincinnati Curtails a Needed Service

FINDING itself short of funds, Cincinnati has decided to curtail some of its public lighting—not that the streets of Cincinnati are the best lighted in the world or that the city is exceptionally free from crime but because its Director of Public Service is lacking in discernment and does not appreciate just what benefits proper street lighting bestows on a community. When electricity was first used for street lighting its fitness for the purpose was instantly recognized. Among those most outspoken in their praises were directors of public safety and police commissioners, who saw in the new light a deterrent to crime. So great was appreciation that it became quite common to say, "An arc lamp is equal to a policeman."

Considering the wide difference between the cost of the lamp and the cost of the policeman, the constant service of the one compared with the other, and the fact that street lighting is the only public service which benefits every man, woman and child in the community, the wonder is that appropriations for street lighting are not twice as large as they are. Certainly no city is overlighted; none, in fact, is even adequately lighted, and for a city of the size and importance of Cincinnati deliberately to weaken its safety and protective measures is shortsighted and blameworthy. It indicates a lack of enterprise which one would not expect in the stanch old city, whose name recalls both Revolutionary and Roman history and which was a flourishing town when Cleveland was a hamlet and Chicago still unborn.

## The Manager of the Small Utility Must Fit His Community

THE executive of a public utility property in the large community has an organization of specialists at hand through which the details of engineering, accounting, legal and operating matters are handled. Such an executive is selected largely for his ability as an organizer, as a man to be respected by the business community of which he becomes a part. The small community executive, however, has an entirely different atmosphere and problem. Not only must he be his own organizer, but he must also bear the brunt and responsibility in almost every line of activity his company is called on to pursue. In addition he must fit into the community's social and commercial life and way of thinking in a manner that makes the people he must deal with feel at home with him and he with them. It is a very difficult problem indeed.

The rôle is rather a large one for one man to fill, especially when the salaries that can be paid are such that they appeal principally to young men just beginning their careers. Yet the problem must be faced in most communities that have utility service, for, after all, there are few great cities and an overwhelming number of lesser communities.

One Middle West syndicate with small-town properties has found that the point in which the managers in such places most often fail is inability to get the viewpoint of the community, talk its language and be a part of it commercially and socially. This particular syndicate is now making it a practice to employ a local man with some practical experience in operation who has, either by being brought up in the community or by long residence in it, established himself as an honorable and upright individual in whom the public has confidence and who has a record of business experience sufficient to justify the general estimate of him.

With a man of this kind at the head of a local organization, the executives of this particular company feel that any technical and operating shortcomings he may have can be supplied under the existing system of syndicate management and operation, and that he can be depended on to ask for help in the problems on which he may lack experience. Public confidence, it is held.

can rest only on the personality of the man himself, and the selection of men for executive positions in the smaller communities must rest largely on the way in which they measure up in this regard.

### Give Adequate Support to the Meter and Test Department

SOME operating companies provide excellent meter and test facilities. Others overlook them or neglect them entirely. Why this should be so is hard to understand when one considers the fact that meters are the cash registers of electric service systems and are more liable to under-register than over-register. Furthermore, why isn't it more generally recognized that trouble forestalled in other apparatus means a saving in investment, operating expense, revenue and good will? Adequate testing facilities plus scheduled inspection and maintenance are the means of forestalling trouble.

It seems axiomatic to state that the meter and test department to be effective should be provided with the necessary testing apparatus and that it should have convenient space in a building which is centrally located for the work handled. The head of the meter department may have some ideas regarding the apparatus he needs and the building space and location preferred. Usually it will be found that most of his desires can be satisfied at an expense that will bring a neat return on the investment if the intangible as well as the tangible results of inadequate test facilities are considered.

### Wire Covering for Overhead Lines Gives False Sense of Security

IF THE proposed requirement that approved weatherproof or rubber insulation be provided on all overhead conductors operating at potentials up to 5,000 volts is included in the new edition of the National Electrical Code (up for final public hearing Monday, March 12), it is bound to give many persons a false sense of security. In reality such insulating covering has very doubtful protecting value at voltages above 2,300 and questionable value even at this voltage after being in service a short time. Central-station operating practice has rather generally been built on the basis that the insulating value of weatherproof covering is so uncertain that, for their own safety, workmen must be instructed to proceed on the assumption that all conductors being worked upon are bare. This practice is based on a sound foundation of experience, and there is no development in view that promises a reasonably priced insulating covering which will withstand the effect of climatic conditions indefinitely and retain its insulating value. Despite this condition, the sole basis on which advocates of this proposed addition support it is the assumption that weatherproof covering has some protective value part of the time and for that reason should be used. It is this uncertain value that makes its use most hazardous. Even if it is used to prevent accidental swinging contact, there is every likelihood that the covering will become abraded by rubbing contact and not provide the protection intended.

There is another reason why weatherproof covering should not be used on all conductors up to 5,000 volts, and that is that it increases the diameter exposed to wind and sleet nearly 100 per cent and increases the hazard of wires breaking. Another factor is that the requirement of a weatherproof covering of doubtful effectiveness would increase unjustifiably the expense of rural service.

If insulating covering be advisable for all wires up to 5,000 volts, it is surprising that this requirement is so briefly covered in the National Electrical Safety Code. As a matter of fact, a provision of this character was withdrawn from the National Electrical Code in the 1920 edition. The most dependable way of removing any life or fire hazard that may exist from close proximity of wires of the class considered to other objects is to provide ample clearances and safe construction, as is done by progressive companies and prescribed by the National Electrical Safety Code.

There is no reason to believe that central stations and others will discontinue the use of weatherproof wire where they now employ it. But it is best to defer the inclusion of the proposed blanket requirement for all wires up to 5,000 volts until it can have more complete consideration.

### Outdoor Construction Should Not Become a Fad

THE growth of sentiment in favor of putting apparatus out of doors instead of under a roof has been an interesting phenomenon. Ten years ago the radical who suggested putting switches or transformers out of doors to save space and expense within the four walls of a station was looked on as a fit subject for the psychopathic ward. Rather gradually, as becomes the spirit of the conservative, a change in opinion came about. The first open-air switches were installed often from sheer inability to meet architects' bills. They were followed by out-of-door transformers and by substations in their entirety. More recently there have been, as will be remembered from published descriptions, some very useful experiments in outdoor generating stations. Now the key to the whole situation is a golden one. Broadly, there is no particular reason for designing weatherproof apparatus, save that its extra cost will be less than that of constructing inclosed space in which to stow it. In very high-tension work part of this extra cost is implied in the provisions for getting circuits into and out of station structures.

The early step to mere utilization of air switches whenever practicable was a simple one, very logically followed by putting the transformers out of doors so that only low-tension circuits would have to enter or leave the station building proper. There was the collateral advantage that the exit of the transformers took with it a further amount of switchgear.

The whole matter of "going the limit" and putting the generators out of doors is really one of climatic conditions. There are cases in tropical and subtropical climates where, save for a roof to shed the sometimes heavy rains, a building in the ordinary sense seems superfluous. In our Northern climate protection for the station staff, if not for the apparatus, is essential. In hydro-electric plants the wheels, like the penstocks, have not infrequently been placed in the open and driving shafts brought within the station for the comfort of the attendants. From an operative standpoint almost any class of equipment can be made sufficiently weatherproof to permit its successful operation out of doors, but does it pay? Generally speaking, it is doubtful, as regards the mass of the generating apparatus and auxiliaries. That it pays for transformers and their accessories is due chiefly to the fact that the ac-

cessories have gradually taken up more and more room and involved more and more cost to a point where one almost can say that the tail is wagging the dog, the switchboard swamping the rest of the equipment so far as the balance sheet is concerned.

If the engineer rigorously holds down costs in the matter of mere structure, he is very likely to gain enough in convenience and cost of the general station equipment to be worth the while. If he feels it necessary to employ switching apparatus that must be installed in a bombproof structure, it does not make much difference whether that structure is under a roof or not. If the transformer leads can be properly protected by roofing in or otherwise, there is certainly gain in keeping high-tension equipment where plenty of air, one of the best and cheapest insulators, is available. The main ends to be sought are simplicity and reliability, and it is well to remember that these may be sacrificed out of doors to just as ill effect as under a roof.

## Theory Now Needed in Practice

THE so-called practical engineer has done a splendid job in this country. He was the rough-and-ready type who could adapt the new discoveries in the electrical art to utilitarian purposes in order to meet the demands of a young, vast and rapidly developing nation. His scale of achievement cannot be matched elsewhere. It has placed America in the front rank as regards the number and extent of electrical installations.

During this era of strenuous pioneering the practical engineer was prone to ridicule the theoretical engineer —also so-called. The theoretical engineer of that period was typified by the foreign technician whose problems were associated with minor and small-scale developments in old and well-developed localities. The practical engineer had no scholarly leisure to delve into the unknown, no incentive to achieve perfection and no necessity for checking up carefully the economical and technical performance of his equipment. It was natural for him to label theoretical treaties "pipe dreams" and to adopt the motto "Practice makes perfect."

Today conditions have changed. No longer is there the imperative demand for engineering exploitation of virgin territory or readily available natural resources. Today's problems are connected with the economical operation, consolidation and remodeling of existing systems and with the demand for technical accuracy in the selection and operation of engineering equipment and installations. Now the theoretical engineer is called into commercial practice, and the operating and practical engineer of the old school often finds himself handicapped. In electrical engineering as in no other branch theory has reached a plane far above operating practice, and there is an imperative call for the closer coordination of theory and practice through the education of the operating personnel, which, of course, includes many high-grade practical engineers.

Few operating engineers remember much more than the rudimentary mathematics and electrical theory they learned at college, yet the efficient performance of their work necessitates the use of hyperbolic functions in transmission, Kirchoff's laws in distribution, the dielectric circuit in cable practice and fundamental theory in dealing with transients and protective equipment. Exponential functions and calculus are necessary tools for the solving of practical problems. Indeed, calculus is considered elementary mathematics today by the theoretical specialists, if their literary productions be accepted as criteria.

In order for the operating engineer to select, operate and install economical and properly rated lines and cables, breakers and switches, motors, arresters, relays and meters, he must either increase his theoretical proficiency or be at the mercy of a small group of theoretical engineers in the ranks of electrical manufacturers and consulting engineering firms. "Cut and try" and guesswork are alike out of date in the economical operations of today, and the practice of copying other installations is no longer to be commended in highly refined, extensive and complicated engineering activities.

To wed electrical theory and electrical practice is a real job, and much work must be done before it is accomplished. Professional engineering societies serve, among other things, as clearing houses for the production of certain specialized theoretical papers which can be understood by a very limited number of specialists and by still fewer operating engineers. These papers must be interpreted, and the specialists must be drafted into the educational scheme to educate all engineers in the theory of their art. The schools can do good work by furnishing extension courses, textbook material, lecture courses and other helpful facilities. The technical press is an active agency in interpreting and in carrying out the educational program. The whole industry should change its attitude toward the value of theoretical training and take active steps to bring theory and practice nearer together.

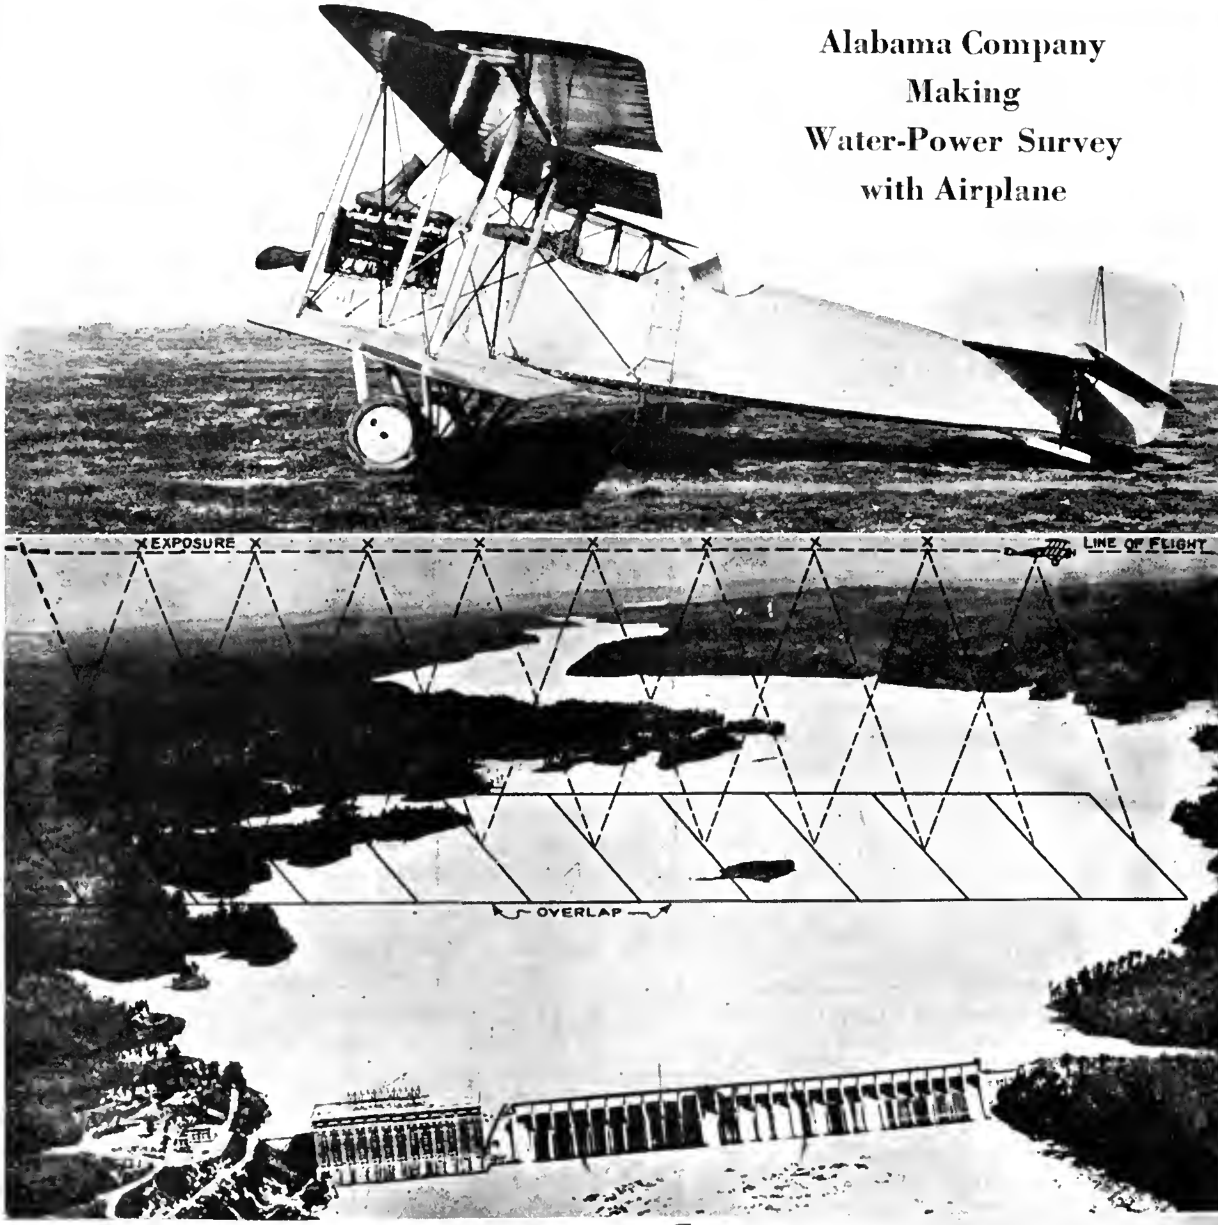
## Too Great Haste Makes Waste

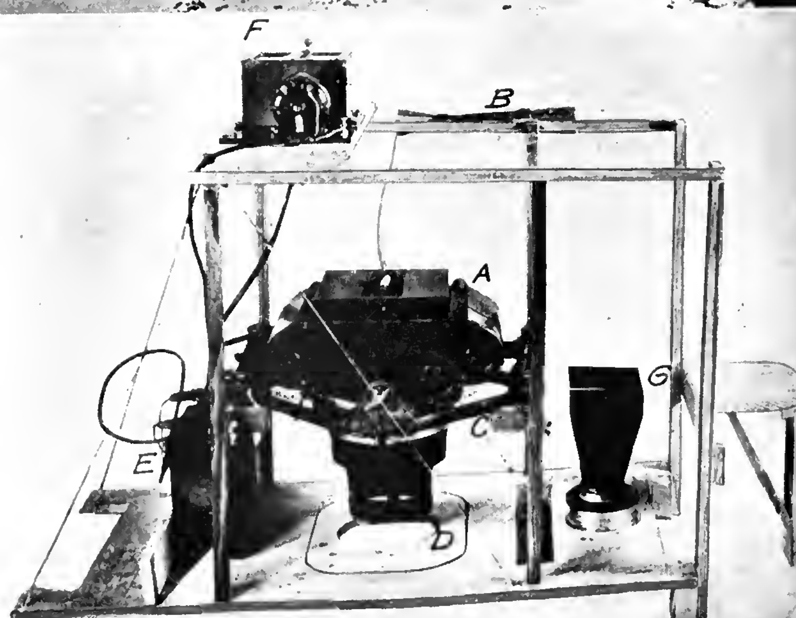
MAKING estimates on a "wanted day before yesterday basis" because some executive feels that he cannot take the time to make a thorough investigation, or does not know that it takes time, is the nightmare that many an engineer experiences daily. Generally the individual who is responsible for unreasonable demands is a man with a financial viewpoint only, or of the type known as a "go-getter."

It is refreshing to hear a banker take this sort of thing to task as did H. D. Thrall, vice-president of the Minnesota Loan & Trust Company, recently in an address before the Engineers' Club in Minneapolis. Mr. Thrall seriously questions whether we are not sacrificing more to speed than is really necessary. He points to the habit engendered during the war of doing things regardless of cost and without proper attention to preliminary detail, because human life and the fate of military movements depended on getting such things done, as one to be broken and a return to sane planning and building encouraged.

Incompetent engineers have produced many a bad plant such as Mr. Thrall mentions in his talk, but many more mistakes have been made because some one in authority forgot that raising the money to carry out a project still leaves the physical project as far from completion as ever. Accuracy and vision can be expected in engineering work only when the engineer, in addition to being competent, has time accorded him to make a thorough investigation. "Wanted day before yesterday" and "I want what I want when I want it" are executive attitudes that cause far more serious errors than engineering incompetency.

# Alabama Company Making Water-Power Survey with Airplane





By CONDUCTING an airplane photographic survey instead of the ordinary land survey, the Alabama Power Company expects to make a thorough study of the relative merits of water-power development on the Tallapoosa River in about sixty to seventy-five actual hours of flying, and besides save about 50 per cent of ordinary cost of surveying. The company estimates that it would take a land survey force at least eighteen months to do the same work if that force were no larger than the one which is to be employed for the air survey.

The plane which will be used is of the Breguet bombing type capable of carrying five passengers, a pilot and 600 lb. of equipment at a maximum speed of 135 miles per hour. An Eastman "K1" camera with a single-focus lens of 10 in. will be mounted over an aperture in the cockpit of the airplane and will contain a roll of film 75 ft. long, sufficient for 100 exposures.

# Some Economic Phases of Engineering—II

### Methods of Procedure When Cost, Efficiency, Load or Other Curves Must Be Analyzed for Economic Study of Engineering Design—Specific Handling of Turbine Water-Rate Curves Used for Illustration

By GEORGE F. MARSTELLER

*Electrical Engineering Department, Utica Gas & Electric Company*

SOME economic phases of the engineering study necessary prior to the replacement of a turbo-generator were discussed in a previous issue, a general method being described. Since special analysis is sometimes required, it seems advisable to look further into this particular type of problem. In the previous illustration a practically constant load was tacitly assumed; that is to say, for $8{,}760T_L$ hours per year, there was a constant load of 7,500 kw., differing from this value, more or less, for a total time which is such a small percentage of $T_L$ that these deviations from 7,500 kw. can be neglected. Though such a condition is true of much power-consuming apparatus or equipment, it rarely represents the state of affairs of a power-producing device, as a turbo-generator, for example.

For studying the relative economic advantages of increased efficiencies in the particular case of a turbo-generator, reliable or guaranteed water-rate curves must be insisted upon. At the present stage of development the writer is not aware of any manufacturer that either can or will guarantee the steam consumption of a turbine per kilowatt-hour to a degree of accuracy including the second decimal point, under all conditions of vacuum, pressure and superheat. Owing to unavoidable factors such as deposits or wear on bladings, changes in clearances, etc., a water-rate curve is not absolutely constant in shape or position. However, by obtaining reliable curves for the most favorable and most unfavorable working conditions as to pressure, vacuum, superheat, etc., a trustworthy comparison could still be carried out.

Since we are dealing here with relative rather than absolute thermodynamic efficiencies, the factors which cause instability from external and internal sources are inherent in all types, and unless the design represents a radical departure in principle or construction, these inherent factors most probably affect to the same relative degree the machines being compared and therefore annul each other for the purpose of economic comparison. Where this is known not to be the case, allowance for additional contingencies must be made. Fig. 1 represents the guaranteed water-rate curve obtained by test of a modern compound turbo-generator of 60 000 kw. capacity, taken at 28½ in. vacuum referred to a 30-in. barometer.*

Speculating upon these conditions as being fixed, it is evident from the curve that a gain of only 1 per cent in efficiency at a full load of 50,000 kw., with an annual running time of say 5,000 hours and an evaporation of 8 lb. of water per pound of coal, the latter costing $3 per ton, would result in a yearly saving of:

$$Sa = 50{,}000 \times (10.93/8) \times 3 \times R_M = \$5{,}117,$$

where 10.93 is taken from water-rate curve. (Here $R_M = 0.02497$ corresponds to $T_2 = 5{,}000/8{,}760 = 57$ per cent, $E = 1$ per cent. (See Fig. 1, ELECTRICAL WORLD, January 27, page 217). That is, under the conditions assumed, a reduction in pounds of steam per kilowatt-hour from 10.930 to 10.8207 would net a yearly saving in coal of $5,117, which is an appreciable sum.

However, with a constantly fluctuating load the water-rate curves to be compared may have such a shape that a gain in efficiency at one load might result in no advantage, a very insignificant gain, or even a loss in efficiency, at other loads. Since in the most general case the loads and thus the relative efficiencies will vary at all times, it becomes necessary to examine the sum-total effect throughout the entire range of all points of the load range.

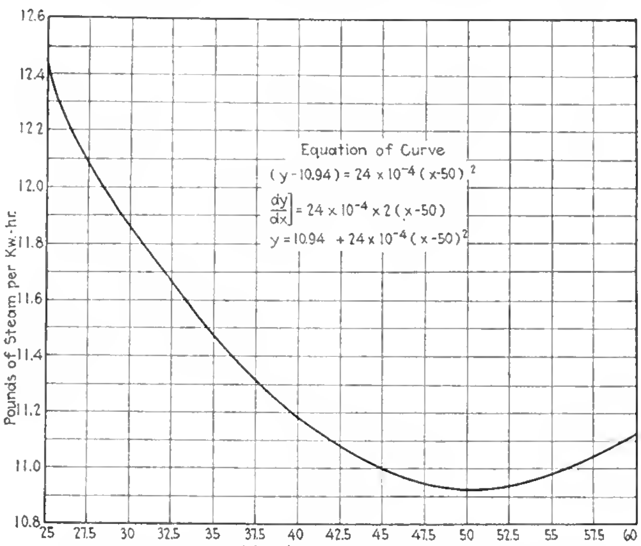


FIG. 1—WATER-RATE CURVE OF MODERN 60,000-KW. CROSS-COMPOUND TURBO-GENERATOR TAKEN AT 28½-IN. VACUUM REFERRED TO A 30-IN. BAROMETER

The curve in Fig. 1 is remarkable for its general characteristics, not only from the point of view of operating performance, but, as examination will show, because it follows very closely a parabolic law of the form $(y - a) = k(x - b)^2$, such that in this case $y = 10.930 + 24 \times 10^{-4}(x - 50)^2$, and therefore the rate of change of pounds of steam per kilowatt-hour, or the stability of steam consumption for the various loads, would be expressed by the differential of the parabolic equations above, which gives a straight line such that the rate of change along the parabola—i.e., the slope of this straight line for any value of $x$—is equal to:

$$dy/dx = 48 \times 10^{-4}(x - 50).$$

Unfortunately, most water-rate curves cannot accurately be expressed by the simple parabolic equation

*Courtesy *Electric Journal*, May, 1921.

above, though in many cases an approximate equation can be had by assuming it to have a general parabolic form with displaced vertex.

Also, for some curves the potential series $P = P_0 + AL + BL^2 + CL^3 + DL^4 + \ldots$ gives satisfactory results, where $A$, $B$, $C$, $D$, etc., are coefficients found by solving the simultaneous equations formed from letting the approximate curve to be determined run through several corresponding points $P$ and $L$ on the actual curve already given by test. Usually an equation of the fourth degree is sufficient for all practical purposes.

In most instances, however, the mathematical advantage of dealing with such curves as exact equations is outweighed by the very laborious processes of obtaining them. This is especially true when simpler, even if somewhat less approximate, methods can be suggested, and the merits of each case to be dealt with become then a matter of judgment and experience.

### Method of Comparison

In the attempt to look into these salient features more explicitly, let Fig. 2 represent some typical daily load curve as applying to $N$ days per year, the remaining days being idle; that is, the time-load factor $T_L = N/365$.

If the typical daily load curve for one part of the year differs radically from another part of the year, an analysis would have to be made for each case individually and their effects studied collectively in order to determine the proper contribution of each toward the total economic effect.

Striking blind averages between extremes often reduces the most laborious study to a piece of scientific guesswork, thus making it useless as a dependable guide. For simplicity, Fig. 2 is assumed to be the typical daily load curve of the only turbo-unit present. However, if the main bus is supplied by several alternators running in parallel, and possibly all of different rating, it would even then in most cases be necessary to obtain individual load curves by metering the kilowatt-hour output of the particular unit under consideration. In some isolated cases, where the load variation is known never to exceed definite limits, the governors of all but one machine are held fixed, thus compelling the fluctuations in load to be taken up by this single unit. Where this is not the case, we are justified in considering the division of the total power-component load as proportional to the several units only, provided that the necessary operating conditions as to governor adjustment, etc., are maintained.

Examination of the load curve of Fig. 2 gives a total area below the curve which corresponds to a daily output of 53,570 kw.-hr., and the mean daily load is therefore 53,570 ÷ 24 = 2,232.7, thus resulting in a "daily load factor" of 2,232.7 ÷ 3,360 = 66.3 per cent. Suppose that there was a temporary peak load of 740 kw. superimposed upon the present 3,360 kw. and lasting twelve minutes. It would not affect the average load much, since it would contribute at the most probably only an additional 150 kw.-hr., increasing the mean load from 2,232.17 to 2,238.5 and giving a new "load factor" of 2,238.5 ÷ 4,100 = 54.5 per cent. To evade this conventional but vague, and for many purposes utterly useless, definition of load factor, and in order to gain a more comprehensive insight into the distribution of all loads with respect to the total time we may resort to a replot of Fig. 2 and proceed as follows:

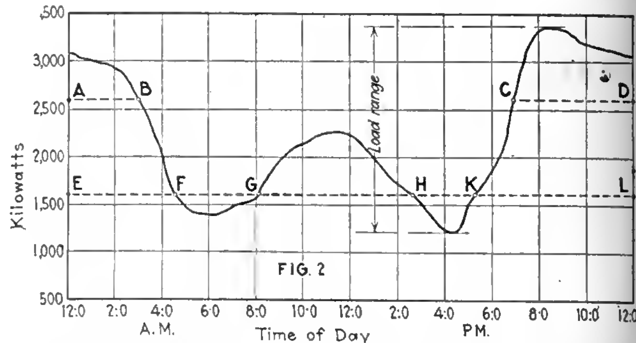

FIG. 2—ASSUMED TYPICAL DAILY LOAD CURVE FOR ANALYSIS

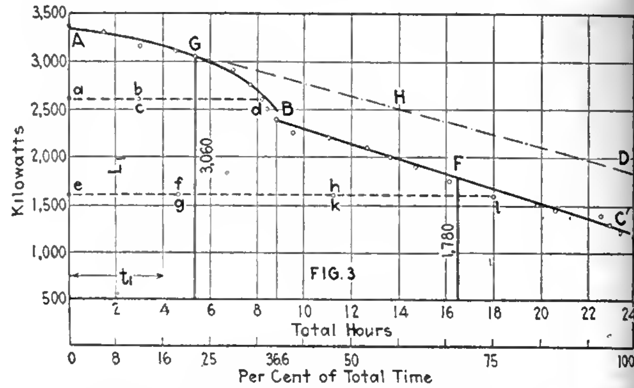

FIG. 3—LOAD CURVE OF FIG. 2 REDUCED TO FORM THAT SHOWS THE SHARE EACH LOAD CONTRIBUTES TO THE TOTAL KILOWATT-HOURS GENERATED FOR THE DAY

Consider the lines *a-d* at 2,600 kw. and *e-l* at 1,600 kw. The former intersects the load from *a-b* and *c-d*; the latter from *e-f*, *g-h*, *k-l*. If we now add the length *a-b* to *c-d*, we obtain a new line *a-b-c-d* in Fig. 3, laid off at the identical load of 2,600 kw. and terminating in *d*, which is one point on the new curve. In like manner *e-f*, *g-h* and *k-l* are laid off at their respective load of 1,600 kw., and a new line *e-l*—being the sum of the three lengths just mentioned, terminating in *l*, is obtained. Connecting the required number of all such points as *d* and *l*, taken for the entire load range of the curve to be replotted, we obtain a new and irregular curve. The area of this latter curve, if an infinite number of points were taken, would represent exactly the same number of kilowatt-hours as the original.

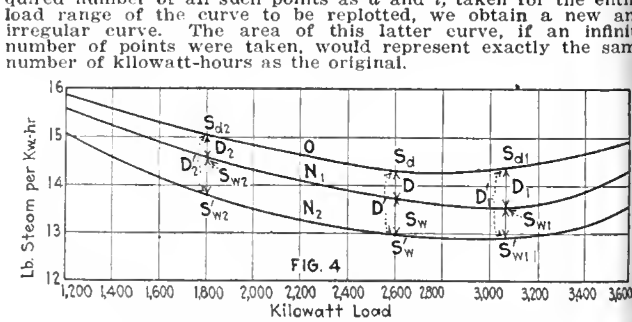

FIG. 4—ARBITRARILY ASSUMED WATER-RATE CURVES TO ILLUSTRATE METHOD OF COMPARISON

Starting with the greatest peak, we draw a series of lines parallel to the abscissa. The spacing of these lines depends upon whether or not critical points or abrupt changes are encountered or whether they pass through sections of the curve where the variations are slow and the slopes more gradual. Out of some twenty lines used in this manner only two are shown in Fig. 2. However, an exceedingly close approximation is obtained by selecting a number of well-chosen points and connecting these by one or two smooth lines, as shown in Fig. 3.

This new curve does not reflect the variation of load with respect to the clock or time of day, as usual. It rather represents the share which each load is contributing toward the total number of kilowatt-hours generated. Taking the time-intervals for the period of a length on the abscissa, which corresponds to a total of one hour (collectively) during the day, then the average kilowatts during that interval will be the num-

ber of kilowatt-hours contributed by that load. For example (see Fig. 3), a load of 3,348 kw. contributes 3,348 kw.-hr.—a load of 2,095 kw. contributes 2,095 kw.-hr., etc.—each one for a period of time whose total is one hour, taken collectively, during the period of one day, or twenty-four hours. The smaller the interval we choose, the more nearly does the average kilowatts for that interval approach the *actual* load and hence the actual kilowatt-hours contributed by that load.

Incidentally, a replot such as that shown in Fig. 3 is often a convenient means of expressing very irregular curves or graphs by a single equation, permitting their treatment algebraically. However, when even this replot cannot be very closely averaged by means of a single smooth line or curve, two separate equations will serve just as well, provided that the applicable limits of each are kept in mind. For example, Fig. 3 happens to be such a case. The curve from $A$ to $B$ proves to follow very closely a parabolic law with displaced vertex, thus: $(a - x) = k(y - b)^2$, where $a = 36$ (per cent), $b = 2{,}300$. From this $k = 11/36 \times 10^4$, and hence:

$$y = \frac{600}{\sqrt{11}} \sqrt{(36 - x)} + 2{,}300.$$

Similarly the straight line $B - C'$ is expressible by $y = a - R \times \tan^{-1}\theta x = 3.075 - 18.84x$, where $a =$ intercept with the $y$ axis, $R =$ scale ratio between $y$ and $x$ axes, and $\tan^{-1}\theta =$ slope of line $B - C'$.

To get the average ordinate for the curve $A - B$, its equation may be integrated by the use of the calculus, or since in this case it happens to be a parabola, more directly from the simple fact that the area within a parabolic arc is two-thirds times the area of the circumscribed rectangle. Therefore, we have at once (see Fig. 3): Average ordinate $= 2/3 \times 8.8(3{,}340 - 2{,}500) \div 8.8 = 560$, thus making the total average ordinate $(2{,}500 + 560) = 3{,}060$, as shown. The midway, or average, ordinate for the straight line being evidently 1,780, we have thereby divided our entire daily load curve into two characteristic parts which are representative of actual conditions. One part contributing: 3,060 kw. $\times$ 8.8 hours = 27,104 kw.-hr.; the other part furnishing: 1,780 kw. $\times$ 15.2 hours = 27,056 kw.-hr., giving a total of 54,160 kw.-hr., which compares very favorably with the actual kilowatt-hour output of 53,570. It contains an error of only about 1 per cent.

To avoid the possibility of misunderstanding to the casual reader it may be said that the fact that these two mean loads, taken over unequal intervals of time, contribute almost identical kilowatt-hours, is a mere coincidence.

### FORMULAS FOR GENERAL PURPOSES

Before proceeding to apply the two mean loads of 3,060 kw. and 1,780 kw. above to the water-rate curves of Fig. 4 we may summarize the algebraic relations more generally in order to make them applicable to all cases—not only water-rate curves. Fig. 4 shows a number of purely arbitrary water-rate curves, merely used to illustrate the methods under discussion. Let curve $O$ be the water-rate curve of the old machine and $N_1$, $N_2$ be those of the new machines to be compared. The more unevenly and irregularly these curves are and run with each other within the load range, evidently the more time intervals must be taken on the replot (Fig. 3) in order to apply more closely the particular differences between the curves of Fig. 4 to that corresponding load. We must keep in mind that the abscissa of Fig. 4 corresponds to the ordinate of Fig. 3, and that obviously the particular differences between the water-rate curves, a few of which are indicated by $D_1$, $D_2$, $D'_1$, $D'_2$, etc., are a measure of the gain in comparative efficiencies.

Let:

$N$ = number of days of twenty-four (or $m$) hours each during which the machine is running.

$P$ = number of pounds of steam per pound of coal.

$L_1, L_2, L_3 \ldots . L_n$ = mean loads during the time intervals $t_1, t_2, t_3 \ldots . t_n$

$t_1 + t_2 + t_3 + \ldots . + t_n = 24$ (or $m$) hours (from Fig. 3).

$S_{d_1}, S_{d_2}, S_{d_3} \ldots S_{dn}$ = old steam consumption in pounds per kilowatt-hour at such mean loads as $L_1, L_2, L_3 \ldots . L_n$.

$S_{w_1}, S_{w_2}, S_{w_3} \ldots . S_{wn}$ = new steam consumption in pounds per kilowatt-hour for one prospective machine at such mean loads as $L_1, L_2, L_3, \ldots L_n$.

$D_1 = (S_{d_1} - S_{w_1}),\ D_2 = (S_{d_2} - S_{w_2})$, etc.

$\frac{C}{2{,}000} = C'$ = cost per pound of coal.

$O_d, O_w$ = yearly operating cost in coal of old and new machine to be compared.

$I_n$ = total yearly interest charges.

$M_d, M_w$ = investment on old and new machine respectively.

$V$ = greatest permissible investment in new machine over old one.

Therefore, for the old machine we have:

$$O_d = \frac{NC'}{P} \times (t_1L_1S_{d_1} + t_2L_2S_{d_2} + \ldots . + t_nL_nS_{dn}) \quad (1)$$

Similarly:

$$O_w = \frac{NC'}{P} (t_1L_1S_{w_1} + t_2L_2S_{w_2} + \ldots . + t_nL_nS_{wn}) \quad (2)$$

Thence:

$$O_d - O_w = \frac{NC'}{P} [t_1L_1(S_{d_1} - S_{w_1}) + t_2L_2(S_{d_2} - S_{w_2}) + \ldots . + t_nL_n(S_{dn} - S_{wn})] \quad (3)$$

$$= \frac{NC'}{P} [t_1L_1D_1 + t_2L_2D_2 + \ldots . + t_nL_nD_n]. \quad (4)$$

In some special cases it is more advantageous to express $t_1$, $t_2$, $t_3$, etc., in per cent, if the gain in efficiency is also expressed in per cent, so that $E = 1 - (S_d/S_w) = (1 - k')$, and $R'_M = T_2E$, which can be read off a suitable diagram such as Fig. 1, ELECTRICAL WORLD, January 27, page 217. Then equation (4) becomes:

$$O_d - O_w = \frac{mNC'}{P} [L_1S_{d_1}R'_{M_1} + L_2S_{d_2}R'_{M_2} + \ldots + L_nS_{dn}R'_{Mn}] \quad (5)$$

By making $t_1 = t_2 = t_3 = \ldots . = t_n$, where $t_1 + t_2 + t_3 + \ldots t_n = m$ hours, and $n$ is the total number of equal time intervals on the replot of the load curve (as Fig. 3), then $t_1 = t_2 = t_3 = \ldots = t_n = m/n$, (6)

and equation (4) can be written:

$$O_d - O_w = \frac{NC'm}{Pn} \times (L_1D_1 + L_2D_2 + L_3D_3 + \ldots L_nD_n), \quad (7)$$

and if, for example the value of $P$ (the pounds steam per pound of coal) is also a known variable for certain conditions, as obtained from a boiler load curve, then equation (7) becomes:

$$O_d - O_w = \frac{mNC'}{n} \times \left( \frac{L_1 D_1}{P_1} + \frac{L_2 D_2}{P_2} + \frac{L_3 D_3}{P_3} + \ldots + \frac{L_n D_n}{P_n} \right) \qquad (8)$$

If in any unusual case the comparative curves (in Fig. 4) should overlap, then the respective term or terms, including this interval of overlap in any of the equations above, would be preceded by a sign opposite from that which precedes them here.

## Numerical Evaluations

In order to make this method more readily usable a few numerical solutions will be evaluated from the expressions developed above. Assume $P = 8$, $C' = 3.2/2{,}000$ and $N = 300$; then, using equation (3), the two mean-load values over the two unequal time intervals as previously derived from Fig. 3, and by aid of Fig. 4, we have:

$$O_d - O_w = \frac{300 \times 3.2}{8 \times 2{,}000} \left[ 8.8 \times 3{,}060\,(14.40 - 13.55) + 15.2 \times 1{,}780\,(15.05 - 14.60) \right]$$

$$= \frac{9.6}{160}\,(22{,}888.8 + 12{,}175.2) = \$2{,}103.84.$$

If we now take six equal time intervals, we are justified in assuming by inspection that each interval in both Figs. 3 and 4 is small enough to insure that each part of the curves covered by each interval will in no way seriously depart from a straight line. Therefore, the midway ordinate of each interval very closely approaches the actual average for that interval, and by using this method in connection with the replot we can obviate the necessity to determine either the areas or the equations of any curve. From equation (6), $m/n = 24/6 = 4$ (number of hours covered by each interval). The values for $L$ and $D$ are read from Figs. 3 and 4, and the various results as required from equation (7) may be conveniently arranged as shown in the accompanying table.

METHOD OF TABULATING CALCULATIONS AND DIFFERENCE IN RESULTS DUE TO SELECTION OF EQUAL TIME INTERVALS

| $m/n$-Hour Intervals | I | II | III | IV | V | VI |
|---|---|---|---|---|---|---|
| Corresponding: $L$ | 3,265 | 2,985 | 2,300 | 1,980 | 1,680 | 1,375 |
| Corresponding: $S_d$ | 14.50 | 14.33 | 14.52 | 14.84 | 15.20 | 15.60 |
| Corresponding: $S_n$ | 13.67 | 13.53 | 13.98 | 14.32 | 14.74 | 15.27 |
| $S_d$-$S_w - D$ | 0.83 | 0.80 | 0.54 | 0.52 | 0.46 | 0.33 |
| $LD$ | 2,710.0 | 2,388 | 1,242 | 1,029.6 | 772.8 | 453.75 |

Then $\sum L = 13{,}585,$

also $\sum LD = 8{,}596.1;$

hence, $m/n \times \sum L = 54{,}340$ kw.-hr., which compares well with 53,570 kw.-hr. from original load-curve, and

$$\frac{mNC'}{nP} \times \sum LD = \frac{24 \times 300 \times 3.2}{6 \times 8 \times 2{,}000} \times 8{,}596.1 = \$2{,}063.06.$$

showing a difference as compared with the previous solution of:

$$(2{,}103.84 - 2{,}063.06) = \$40.78.$$

Therefore:

$$V = M_d - M_w = 2{,}063.06/I_n, \text{ etc.}$$

(See Electrical World, Jan. 27, 1923, page 217.)

If we had used twelve equal time intervals with their corresponding twelve-mean $L$ and $D$, our result would have been 2,072.52 instead of 2,063.06—an error of less than one-half of 1 per cent, thus showing no corresponding gain in taking too many time intervals.

If the load on a machine, equipment or system, as reflected by its typical daily (or yearly) load curve, is known to increase gradually during a predicted or predetermined period of years (i.e., if, for example, the load curve assumes a shape and location as represented by *A-G-H-D* in Fig. 3), another condition arises which must be taken into account. Evidently it would be unfair to base our calculations on the initial or on the final state of affairs. The basis must be somewhere between and such that the exact location is determined by the weight average of characteristic portions of the present and probable load curve.

Assume, then, for illustration that one typical portion of the loads (higher values, lower or both) have

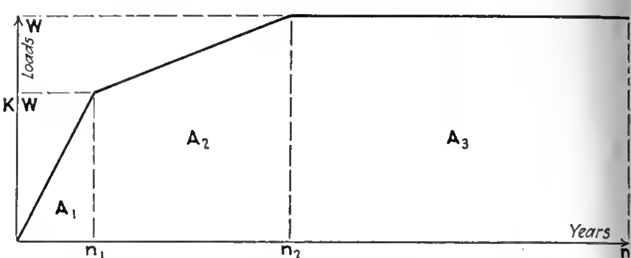

FIG. 5—METHOD OF CONSIDERING RATE OF LOAD GROWTH. THIS METHOD AVOIDS TREATING ONLY THE INITIAL AND FINAL LOAD CONDITIONS

a probable rate of growth determined by the diagram of Fig. 5.

Here, $W$ = maximum rating of the machine; $KW$ = fractional part of $W$; $n_1$, $n_2$, $n_3$ = corresponding of years; $A_1$, $A_2$, $A_3$ = corresponding areas of $n_1$, $n_2$, $n_3$ where $n_3$ is the end of useful life, owing to obsolescence, inadequacy, etc.

$$A_1 = KWn_1/2;\; A_2 = KW(n_2 - n_1) + W/2(1 - K)(n_2 - n_1)$$

$$A_3 = W(n_3 - n_2)$$

therefore the total area $A_T = A_1 + A_2 + A_3$ divided by the total number of years or $n_3$ gives the average load $W_g$ upon which to base our calculations, and this reduces to:

$$W_g = A_T/n_3 = W + W/2n_3[(K-1)n_2 - n_1]$$

From what has been indicated previously, a similar comparison could be carried out between the curves $C$ and $N_2$ or $N_2$ and $N_1$ of Fig. 4. In general, any number of curves of any shape can be examined simultaneously—curves, for instance, representing cost of coal with the number of years, fluctuations in wages, water rates, boiler efficiencies, load-variations; etc.

## Two Types of Magnetic Testing

The routine magnetic testing of the Bureau of Standards has been placed on a new basis which provides for two classes of tests. Class A will be restricted to specimens which are sufficiently uniform in dimension and magnetic properties along their length to justify the employment of test methods of the highest accuracy intended for use as standards for the calibration of testing apparatus and for other uses where high precision is necessary. Class B tests will be made in general in cases where the material is not sufficiently uniform to justify the use of precision methods or where the highest accuracy is not necessary. Circular 85 describes the tests in more detail and contains a schedule of prices.

# Effect of Coal Supply on Public Utilities*

## Essential Character of the Business Necessitates Constant and Adequate Supply of Suitable Coal, as Well as Ample Storage, to Insure Against Interruptions of Service—How Public Utilities Conserve the Nation's Coal Resources

By JOHN W. LIEB

*Vice-president New York Edison Company and Chairman of Joint Fuel Committee of Three National Utilities Associations*

THE development of the public utilities to their present size and importance where they serve practically the entire population of the United States has occurred largely in the last forty or fifty years. At present nearly one-third of our industries are supplied with power by central electric power stations. The total number of consumers for lighting and power exceeded ten million in 1922. Gas was supplied in 1921 to more than nine million consumers. The street railways in 1922 carried more than fifteen billion passengers. Here are a few significant public utility statistics: The total capital invested in 1922 (including gas companies) exceeded $15,000,000,000; the total kilowatt capacity of dynamos in central electric stations and electric railway stations exceeded 15,000,000 kw.; the outputs of these stations was 46,000,000,000 kw.-hr., and the number of employees was estimated at 525,000.

The magnitude of the public utilities may be realized by comparing their $15,000,000,000 of capitalization with the valuation of all of the class 1 railroads of the United States, estimated at approximately $20,000,000,000.

The essential importance of the utilities to the public welfare is also indicated by the importance and variety of useful service they render. Electric and gas lights are essential to the policing of our great cities. Fire protection, water supply, telegraph and telephone service and vertical transportation are all largely dependent for their operation on central-station service.

Domestic lighting, heating, cooking and many other household functions are dependent in our cities upon the utilities, as in like manner are urban and interurban transportation, shops, factories of all kinds, the manufacture of artificial ice, and so forth. The industrial uses to which electricity is now put are legion.

The utilities through their economical operation and low cost of energy are making possible the supply of greater and greater amounts of power for industrial workers, and, paralleling this increase, workmen are able to produce a greater value per worker through increased output.

A comparison, through a reasonably stable period, of the average horsepower available per workman and his increased productiveness shows that in 1899 the horsepower per worker was 2.12 as against 3.10 in 1914, while in the former year the annual value added to products per wage worker was $1,025, as against $1,404 in the latter. Though the output per workman is undoubtedly influenced by many factors, this increase in the application of mechanical power as a substitute for manual labor is undoubtedly a cause of the rapidly increasing wealth of the country and the emancipation of workers from drudgery and heavy labor. Largely through supply of adequate power deftly applied by American genius will this country in the coming years be able to hold her leading place in the markets of the world and still maintain for its workers the high plane of American living conditions.

The United States has outstripped the world in the total consumption of electrical energy, using about half of all the power produced and far exceeding her principal competitors. The kilowatts consumed per capita in the United States amount to 472, as compared with 163 in the United Kingdom and Ireland, 147 in France, 141 in Germany and 85 in Italy. Three small countries, Switzerland, Canada and Norway, which have large available water powers exceed the United States in the per capita consumption of electrical energy and have in that regard a material economic advantage.

### Utilities Must Have Constant Fuel Supply

The services of the utilities have become so essential to our industrial and civic life that should the electric and gas plants of a great city fail to function an inconceivable catastrophe would result. The public requires that the utilities maintain the continuity of service as a necessity to its health, safety and comfort, and it demands that the utilities keep in constant readiness the equipment and facilities to carry whatever load may be forced upon them, no matter how high or unexpected the demand or how adverse the circumstances. In order to do this it is evident that there must be available at all times adequate quantities of suitable fuel. During the past few years adequate supplies of coal of this character have not at all times been available. The public utility must function, and coal is the raw material upon which its service usually depends. For the public good it should, therefore, be placed beyond any danger of failure to obtain adequate quantities of proper fuel.

### The Coal Industry

During the past few years the gas and electric utilities have had great difficulty in obtaining coal of the proper quality and in the amounts needed. The supply was unreliable, the principal causes being strikes, car shortages and failures of transportation, due to congestion of equipment, resulting embargoes, etc. Yet the production of bituminous coal has not varied greatly during the last ten or twelve years. In 1910 the mines produced 416,000,000 net tons; in 1918 580,000,000 net

*Abstract of an address delivered before New York Electrical League, Feb. 28, 1923.

tons and in 1920 569,000,000 net tons. The increase from 1910 to 1920 was therefore 37 per cent.

The estimated percentage of distribution of bituminous coal mined is as follows: Industrial uses, 31.6; railroads, 27.7; electric power utilities, 5.7; domestic, export, coke and gas making, bunkering, etc., 35. The electric utilities used in 1922 34,000,000 tons of anthracite and bituminous coal.

Isolated power plants consume about two-thirds of the 31.6 per cent consumed for all industrial uses, or about 20 per cent of the total coal mined. A comparison of this consumption with that of the utilities, amounting to only 5.7 per cent of the total, indicates the high fuel economy of the utilities when the relative outputs of electrical energy are compared. These data were collected in an exhaustive study covering a number of states and the results demonstrated that the electrical utilities generated annually more energy than the aggregate produced by isolated industrial plants.

Up to the time of the war the coal business was reasonably constant, and it was not involved in serious straits until the end of 1917. In 1918 our activities in the war caused an excessive demand for coal and made a high peak which could not be fully cared for by our railroads. In 1919 conditions were fair until the advent of the miners' strike on Nov. 1, when production decreased to a low figure for about six weeks. Early in 1920 a heavy demand followed the coal strike, while on April 1, before conditions had become stable, the railroad switchmen's strike occurred. In 1921 the demand was not heavy and supply was reasonably uniform.

In 1922 coal was plentiful in quantity and reasonable in price, considering freight rates, until the great strike occurred on April 1, to be followed by the widespread strike of railway men somewhat later. Though the situation in 1922 was more serious and dangerous than that of 1919-20, it was better handled and the utilities suffered less, though the conditions last year and during the previous coal stringencies were still such as to call for the most earnest consideration.

As is well known, these great disturbances in the coal industry have caused prices to fluctuate enormously. We have not yet recovered from the results of the last disturbance and are still paying abnormally high prices, as has been the case since early in the summer of 1922.

### THE CAR SUPPLY

The opening up of an excessive number of new mines had its reflection on the railroad situation, making it necessary for the railroads to divide their available cars among 2,900 more mines in 1918 and 6,800 more mines in 1920 than would have been necessary had the average production per mine in these years been maintained on the 1910 basis.

Gathering the increased tonnage from a largely increased number of mines calls for vastly increased motive power, coal-car supply and man power from the railroad to serve them all. The number of cars called for, based on the rated ability of the mines to produce coal, kept pace with the increased number of mines until for the year 1920 cars were ordered in sufficient number to load more than 830,000,000 tons—56 per cent more than the total consumption of the country. In the latter part of 1922 cars were called for at the rate of twice the annual consumption of the country.

Under the conditions described, which have existed since 1917, the utilities, as has been said, have experienced great difficulties in obtaining the required amounts of coal of the right character at prices which they could afford to pay under the prevailing rate schedules, framed when coal and labor costs were much lower.

### UTILITY FUEL DIFFICULTIES

The utilities are in a sense agents of the public and must not only provide continuous service, but they hold a distinct responsibility to maintain that service at most economical rates. They are, however, peculiarly vulnerable to the injuries which result from coal crises—first, because they are strictly controlled by the regulatory authorities as to the rates they may receive for their products, and, second, because coal constitutes the absolutely essential and most costly raw material necessary in their processes of manufacture.

Quite uniformly over the United States, public utilities are regulated by public service commissions set up by the several states. They are, therefore, except in a few instances, unable readily to adjust their charges to the cost of coal and thus are at a disadvantage when competing for coal with industrial consumers.

From 20 to 30 per cent of the revenue received for products or service of the utilities is spent for fuel. By the practice of strict economy in every direction the public utilities, both gas and electric, were able to weather the period of excessively high costs during the war. Immediately following the war, however, a number of utilities found it necessary to appeal to the public, through the public service commissions, for increases in rates. In some cases these increases were allowed as applicable to the schedules themselves; in many others the exigency was met by the introduction of a so-called coal adjustment clause or coal charge.

Under the so-called coal clause plan the companies were permitted to add to their base rates, which had been established under low costs of coal, a supplementary charge based on the actual demonstrated increase of cost of coal alone, the companies themselves absorbing the similar large increases in labor, supplies and other items of expense.

These coal clauses became effective generally through the companies filing with the state public service commissions each month a statement as to their actual increases in coal costs, and on the basis of these increases approval was given for the application of the surcharge during the succeeding month. In this way a sliding scale was introduced under which the movement of the coal prices upward and downward became immediately applicable as an element in the rates.

The situation became so serious during or after the strike periods following the war, owing to shortage of production, railroad congestion, etc., that the three national public utility associations were compelled to designate special committees to aid in obtaining coal and to assist in untangling transportation difficulties. During the early summer and fall the joint fuel committee representing these associations found it necessary to intervene to aid more than two hundred utilities in order to save them from curtailment of service. This service has consisted in advising with and appealing to the government where conditions or policies required change, aiding specific utilities in

danger of shutdown through inability to purchase coal, helping to restrain prices and to guard contracts, preventing confiscation, tracing utterly lost coal shipments, and so forth. To do this it was found necessary to have an office in Washington and to maintain continuous contact with the principal administrative arms of the government, with coal dealers and their associations, with the railroads and their associations and with various other agencies which could be of service.

The experience of the utilities has proved beyond question that coal contracts are, as a rule, of little value in obtaining coal during times of extreme emergency unless protected by priority orders issued and policed under government authority.

One of the serious difficulties has been due to the fact that when there is a shortage of coal or of coal cars the supply the utilities receive on their annual contracts is often prorated proportionately with other consumers, some of whom may be "spot" purchasers.

During the periods of stress coal is usually difficult to obtain. Heat value, ash content, volatile constituent and delivery clauses in contracts are not accepted by operators—they can ordinarily sell their coal at these times without any such clauses—and changes in the attitude of mine workers and railroad conditions have often made it impossible for them to accept reasonable specifications. The result of all this has been that "spot" coal purchased to cover contract shortages resulting from these conditions has been exorbitantly high in price and most unsatisfactory in quality.

Little coal was received on regular contract from the beginning of the strike until August.

### UTILITIES REQUIRE COAL OF RIGHT QUALITY

To the electric utilities the question of quality of coal is a particularly serious one. In large electric power plants the kind of fuel which is usable is dependent in large measure upon the design of boilers, stokers, ash-handling equipment, etc. Utility plants are designed and installed with a view to quality and quantity of fuel, and when the coal is not of the character for which the plant was specifically designed serious difficulties result in the form of deteriorated equipment, reduced outputs or even complete shutdown.

The actual value of the coal for steam-making purpose declines rapidly with large ash content, and thus it is with great difficulty, if at all, that the outputs can be maintained when coal of inferior preparation and quality must be used. The following figures give the results of a test of Illinois coal of varying ash content under a standard boiler:

| Percentage Ash in Dry Coal | Horsepower | Percentage Efficiency |
|---|---|---|
| 9 | 690 | 61 |
| 24 | 615 | 51 |
| 35 | 227 | 30 |

It is important to obtain coal complying with a specific analysis from another point of view—the availability of coal for storage. Some coals, while they may be satisfactory in other respects, are unavailable for storage in considerable piles, as becomes necessary where large quantities are involved, owing to the danger of spontaneous combustion. When we have been compelled to accept unsuitable coals, we have frequently had two or three fires going in our coal piles, necessitating rehandling and restacking of the coal with a serious loss due to coking. Owing to the high temperature attained it is also difficult to transfer such coal into barges, the bottoms often burning through, which results in a complete loss of the coal as well as the barge. Coal which is liable to spontaneous combustion also causes extreme difficulty when deposited in the relay bunkers situated immediately above the boilers in the very center of the power houses where a fire is difficult to get at.

Utilities must be provided with fuel of a reasonably definite quality that they can use efficiently, and they have not been adequately cared for when they have been merely provided with some coal. The experience of the utilities covering several years has demonstrated that much unsatisfactory and grossly inferior, badly prepared coal is shipped during periods of fuel and transportation stringency. This not only reduces plant capacity but absorbs railway equipment unnecessarily.

### SOME PROPOSED REMEDIES

Various remedies have been proposed for stabilizing the coal business, though as yet the United States Coal Commission, after several months of intensive study, has not been convinced that a proper solution has been found.

One important group of those interested advocate in essence that the situation be allowed to work itself out without external government or other interferences under the ordinary laws of competition and of supply and demand.

A second suggestion is that the government itself purchase and operate the mines. This plan, though vigorously and continuously promoted by a group of the more radically inclined, has been almost universally condemned by the public on the ground that government ownership and operation has not proved either efficient or economical, and experience with the railroads under government management has not been such as to encourage further experimentation in that direction.

Finally, plans have been proposed whereby through the extension of the storage of coal by all users, by the seasonal variation of prices of coal and possibly seasonal variation of freight rates, by conservation or economy in the use of coal, and by simplifying its distribution, conditions can be materially improved.

Of the methods for ameliorating fluctuating conditions in the coal industry, the proper use of storage seems to offer exceptional advantage. The public utilities for self-protection early inaugurated the policy of maintaining generous storage of coal at their plants. Indeed, they have been leaders in this regard, and through wise buying and handling of storage have proved to be a helpful stabilizer to the coal industry. The large amounts of coal they put in storage prior to the beginning of the great coal strike on April 1, 1922, were a material element in saving the country from a catastrophe of large dimensions.

The following table of days' supply the utilities and all users had on hand in the country at various dates is significant:

| | 1922 March 1 | 1922 Oct. 1 | 1923, Jan. 1 |
|---|---|---|---|
| Coal-gas plants | 82 | 38 | 60 |
| Electric utilities | 54 | 3 | 33 |
| All users | 43 | 21 | 26 |

Larger storage capacities for all coal users, to be filled at times during the year when transportation facilities are best available, would do much to remedy

the present unsatisfactory fuel conditions. The railroads themselves should, in as great measure as possible, haul and store the coal for their own needs during periods when their facilities are not pressed by peak loads.

Further, the mines can in a certain measure promote storage which would prevent the irregular daily production outputs caused by variations in daily car supply. In many locations a coal pocket holding from one to two days' output may be installed at a moderate expense and so arranged as to discharge directly into the railroad cars with little additional equipment and no additional handling. Such a storage should enable the mine to run continually at least five days per week, and the slight additional cost would be largely overbalanced by improved showing in the overhead per ton of coal produced.

Application of electrical equipment in coal mines, while showing steady progress, has not yet reached the rapid development that was to be expected. Electric haulage was reported as in use in 46 per cent of the coal mines reporting, with 11,265 motors, and 51 per cent of the mines used electric cutting machines, although animal haulage and hand methods of mining still prevail to a surprising extent. Of the 3,054,000 hp. used in the anthracite and bituminous industries, about 1,383,000 hp. represented power produced by prime movers at the mines and 888,000 hp. motors operated by purchased power.

### Power Stations at Mines

It has frequently been suggested that much expense and transportation difficulty could be saved to the electric utilities and steadiness of mine output could be promoted by the location of generating stations at the mine mouth and the transmission of the power so generated to the point of use. This has been done in a number of cases in England, on the Continent of Europe and to some extent in America, and it has been found that wherever adequate water supplies exist for condensing purposes the installation has been successful. This condition, however, does not obtain in the majority of cases. Speaking broadly, it must be remembered that for every ton of coal burned in the power station from 600 to 1,000 tons of water must be provided for condensing purposes.

It is unfortunate that very few rivers of adequate size to provide this flow are available in the coal regions, and it is apparent that the object to be attained by placing the station in the coal region has in most cases been impossible of achievement.

The project of pumping coal through a pipe line has been considered by many engineers, and its feasibility has been shown, at least theoretically. The cost and design of the apparatus are well known, and no engineering difficulties are entailed in its operation. A proportion of 50 per cent by volume between material and water can be maintained. At 10 ft. per second, which is not excessive, a 14-in. pipe will carry more than 7,000,000 tons of coal per year, and this delivery is independent of the length of the pipe.

At the present time it is estimated that the cost of delivering a ton of coal, including fixed charges, from Scranton to the New Jersey side of the Hudson would probably not exceed 50 cents per ton, to which would have to be added the ordinary charges for lighterage and handling in the port of New York. It is also probable that bituminous coal could be pumped from either the Broad-Top or Clearfield region with equal facility, but at an increased cost of say $1.25 per ton, although this increase would be well within the cost of railroad freight. It has been estimated that approximately 18,000,000 tons or 20,000,000 tons of coal pass through New York City every year, which would absorb the capacity of three 14-in. pipes.

An advantage of all stabilization methods is that they will tend to furnish more continuous employment to miners and thus improve the economic and social conditions of the mine workers.

### Coal Conservation-Superpower Systems

America is notorious for her extravagance in the use of coal. Moves made to conserve this vitally important natural resource are wise for the protection of the future of the country and also tend to relieve the strain of heavy coal transportation. The public utilities can be of exceptional service in aiding to accomplish this result.

The government Superpower Survey of the Atlantic Coast from Maine to Washington, the report on which was made in 1921, affords a view of what is possible in this regard. It is estimated that power in this region can be supplied with the use of about 2 lb. of coal per kilowatt-hour, as against nearly three times that amount at present. The savings to be obtained would come largely through the possibility of the erection and efficient use of large, highly economical, suitably located power stations, taking advantage of the diversity factor in the varied industries of the several districts covered, lessening the reservation of spare equipment, making possible the electrification of railroads, and so on.

The building of great power systems, interconnected, as contemplated, by the Superpower Zone would make possible utilization of many water powers which otherwise would stand idle.

The electric and gas utilities offer an exceptionally effective medium for simplifying the transportation and distribution of coal. Though this phase of the coal distribution problem is seldom discussed, it nevertheless is one of great and growing importance.

In the power zone heretofore referred to are to be found more than seventy-six thousand industrial plants which use power. Five or six thousand of these use water power as their prime mover, but the great bulk are operated by power generated from steam. If these seventy thousand minor establishments obtained coal for generating their own power, large fuel shipments would have to be sent to seventy thousand points, requiring the time of locomotive and car equipment, and this would involve a material increase in shifting and switching.

However, as about one-third of the power required by these seventy thousand plants is supplied by central power stations, the amount of this detailed coal distribution and local delivery is materially reduced, as this power is generated from coal delivered at a few conveniently located central stations which have available the best modern coal-handling apparatus and commodious storage facilities. Thus today a very material measure of relief has been afforded the railroads through this centralization of coal delivery. If the transfer of the industrial plants of the country is continued, eventually the great bulk of the industrial power coal will be delivered to a few super-plants of great interconnected superpower systems.

It is evident that the public utilities hold wonderful opportunities for advancing the welfare of the nation through the conservation of coal and oil, simplifying the distribution of fuel, contributing to its conservation by the utilization of water power, and providing a supply of abundant, reliable and cheap power to our industries.

In order that their full value may become available to the nation, great systems covering large areas and supplying great loads will be necessary. To accomplish this purpose the utilities must continually expand, ever developing larger and more extended systems. This development is one of state-wide importance, and such public regulation as is needed should be of a state-wide character. Systems of this kind already include scores and hundreds of municipalities within their transmission areas, but they necessarily must be operated as a unit. It is impossible for them to develop or give good service to the public if they are subject to the harassing interference of all of the municipal or minor political establishments through which they may extend and in which they operate. Nor will such a consummation as the public desires and the companies wish to provide be possible unless state-wide regulation of a broad and equitable character is maintained and the laws and rulings governing the utilities are of a helpful and stable character and such as to attract the large quotas of capital which it is necessary to obtain each year to provide for the rapid extension of the public utilities in order that they may serve the public adequately, efficiently and economically.

# Automatic Start Reduces Surges

## Rotor with Two Windings of Different Resistances on 10-Hp. Induction Motor Brings Static Current Down from 550 to 260 per Cent of Full Load Current—Field of Application

TO KEEP down the excessive static current in induction motors without requiring extra compensating equipment has been one reason for the development of the automatic-start polyphase induction motor. A paper on this subject presented before the American Institute of Electrical Engineers by James L. Hamilton, chief engineer Century Electric Company, St. Louis, discusses this development from both mechanical and electrical standpoints.

The stator of this motor is similar to those of other induction motors, but the motor has two windings—one being a progressively wound, low-resistance winding connected to a short-circuiting device, while the other is a high-resistance squirrel-cage design. The high-resistance winding is usually placed near the surface of the armature, thus giving minimum reactance. It can be proportioned to give high static torque with low static current. The low-resistance winding is usually placed deeper in the armature or beneath the high-resistance winding and as a result would have high reactance at standstill due to primary frequency in the armature. However, near synchronism, the frequency in the armature being low, the low-resistance winding also has low reactance; hence good running conditions result.

The motor starts as an induction motor with only the high-resistance armature winding in circuit, thus permitting low static current and high static torque. After the motor has attained a predetermined speed, the low-resistance winding is short-circuited, thus permitting the motor to run with all the rotor copper in circuit, giving small slip, high efficiency and high power factor. The starting winding can be designed for a maximum static torque for a given current, thus limiting the starting current. The running winding can be designed for the best running conditions when the motor attains speed. This type of motor, therefore, has the desirable characteristics of a very high-resistance squirrel-cage motor at starting and the desirable characteristics of a low-resistance squirrel-cage motor when running.

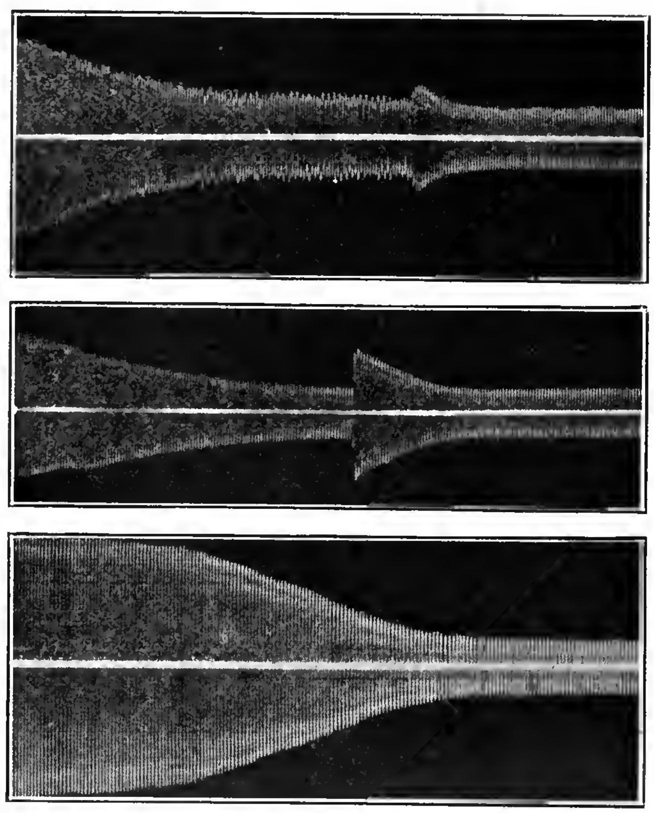

FIG. 1—STARTING CURRENTS FOR SINGLE-PHASE REPULSION-START, THREE-PHASE AUTOMATIC START AND THREE-PHASE SQUIRREL-CAGE MOTORS

| Oscil-logram | Motor Data | Amperes: Static | Amperes: When Governor Operates | Amperes: Per Line | Amperes: Full Load Equivalent Single Phase |
|---|---|---|---|---|---|
| Above— | 10-hp., 440-volt, 60-cycle, four-pole, single-phase repulsion start induction motor....... | 72 | 42 | 24 | 24 |
| Center— | 10-hp., 440-volt, 60-cycle, four-pole, three-phase, automatic-start induction motor. ..... | 60 | 54 | 12.5 | 21.5 |
| Bottom— | 10-hp., 440-volr, 60-cycle four-pole, three-phase squirrel-cage induction motor....... (without compensator) | 105 | | 12.5 | 21.5 |

A study of the static torque and current for various classes of direct-current and alternating-current motors is presented in Fig. 3. From these data it is seen that approximately the same low static current for a given static torque may be obtained from direct-current motors with starting resistance, from single-phase motors of the repulsion-start type, from polyphase induction motors with manually operated resistance in the rotor, and from the automatic-start polyphase induction motor. With a three-phase motor the starting current was reduced from 550 to 260 per cent full-load current with this automatic start, compared with the results obtained using a standard motor without starter.

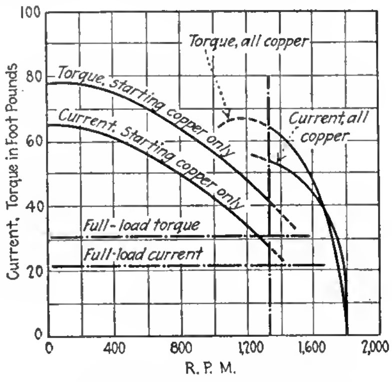

FIG. 2—STARTING CHARACTERISTICS OF 10-HP. INDUCTION MOTOR

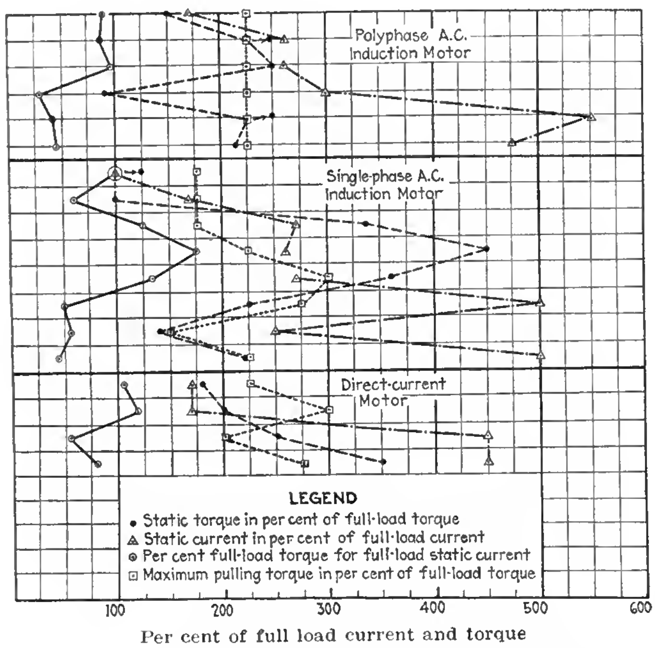


Per cent of full load current and torque

FIG. 3—STUDY OF THE STATIC TORQUE AND CURRENT FOR VARIOUS CLASSES OF MOTORS

TOP SECTION—POLYPHASE ALTERNATING CURRENT INDUCTION MOTORS

Four symbols on uppermost line of diagram: Two-phase or three-phase, wound rotor, 5 hp. with starting resistance.
Second line: Two-phase or three-phase, automatic start, wound rotor, 15 to 50 hp.
Third line: Two-phase or three-phase, automatic start, wound rotor, ½ to 10 hp.
Fourth line: Two-phase or three-phase, squirrel cage with compensator, 7½ hp.
Fifth line: Three-phase, squirrel cage, no compensator, ½ to 10 hp.
Sixth line: Three-phase, squirrel cage, no compensator, ¼ hp.

CENTER SECTION—SINGLE-PHASE ALTERNATING-CURRENT INDUCTION MOTORS

Symbols in first row of squares across diagram in this section: 7½-hp., repulsion start, with compensator starter.
Second row: 7½-hp., repulsion start, with resistance starter.
Third row: ⅓ hp., repulsion start.
Fourth row: $\frac{1}{10}$ to ¼ hp., repulsion start.
Fifth row: 1 hp., repulsion, weakly compensated.
Sixth row: 15 hp., repulsion, strongly compensated.
Seventh row: 15 hp., with $R$ and $X_L$ start.
Eighth row: ⅓-hp. split-phase start.

BOTTOM SECTION—DIRECT CURRENT MOTORS

Symbols in first row of squares across diagram in this section: ½-hp. shunt, with starter.
Second row: ½-hp. compound, with starter.
Third row: ¼-hp. compound, without starter.
Fourth row: ¼-hp. shunt, without starter.

From experience it has been found that a static torque of 175 to 250 per cent of full-load torque is desirable to break the static friction of machinery or apparatus. Since the automatic-start polyphase motor takes a minimum of current from the line during the starting period for a satisfactory static and starting torque, it has been considered favorably by some central stations because it reduces the starting load period. The starting currents are predetermined and cannot be changed by an inexperienced operator.

A representative curve on starting characteristics is given in Fig. 2 for a 10-hp., 440-volt, four-pole, 60-cycle induction motor. These curves have been plotted from observed readings on the motor. The static torque in this case is 75½ lb.ft., or 250 per cent of full-load torque, with a static current of 65 amp., which is 300 per cent of full-load current. The National Electric Light Association states that 75 per cent of the locked rotor current is considered as the starting current, so that the so-called starting current of this motor would be 75 per cent of 65 amp., or 49 amp.—250 per cent of full-load current. As noted in Fig. 1, the starting winding has a maximum torque at or near standstill, which gives the maximum torque efficiency at this point. If the starting winding of higher resistance is used to obtain lower static current, the amount of load the motor can bring up to speed will be reduced. It is always desirable to have no greater current flow when the governor short-circuits the running winding than flowed at the moment of connecting the motor to the line. While the starting copper resistance is nine times the stator resistance, the running rotor resistance is practically only twice the stator resistance. Therefore, the starting copper winding has a resistance of four and one-half times the running rotor resistance.

The weight and size of this type of induction motor for a given speed and rating are practically the same as for a direct-current or a polyphase wound-rotor slip-ring type induction motor.

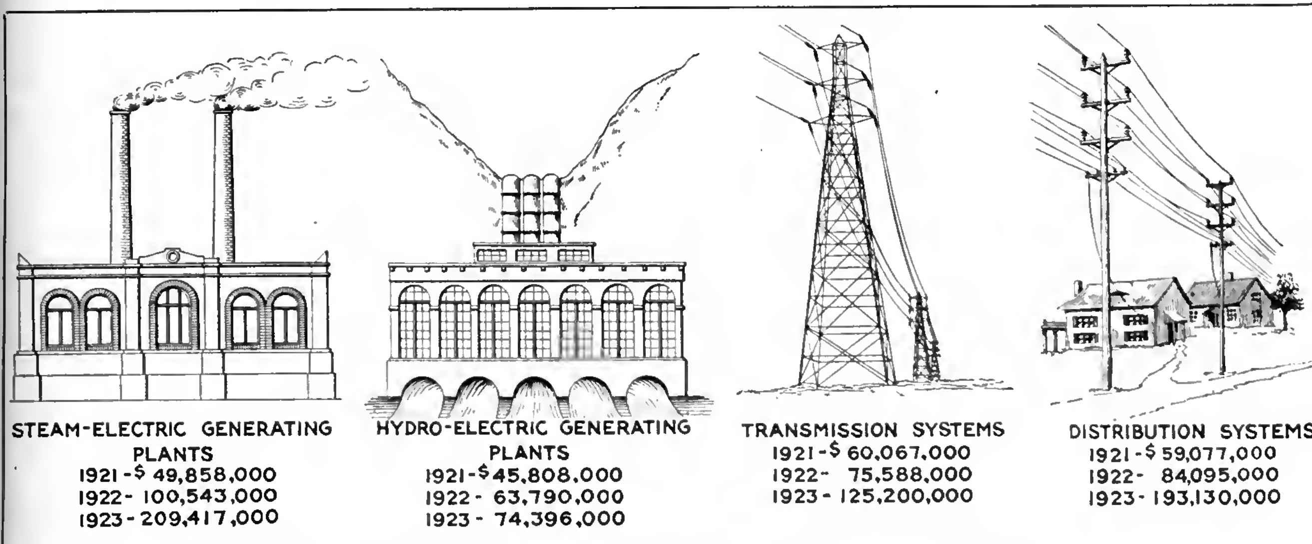
The automatic-start polyphase induction motor is well adapted for operating various kinds of machinery having considerable inertia, or loads that are difficult to start from rest. It is also suited for the operation of machinery where the motor would not be under constant supervision of an operator. It can be started on a fuse or other protective device which will protect the motor under operating conditions. A fuse of 120 per cent of rated current of the motor is usually quite large enough, while a fuse as large as 150 per cent of rated current of motor is never needed.

The oscillograms and the table in Fig. 1 show the starting point for three different types of motors, a single-phase repulsion start, a three-phase automatic start and a three-phase squirrel-cage induction motor without compensator. In this last-named motor it can be seen that the static current swings up to 105 amp. while the automatic-start induction motor had an amperage of only 60.

The starting efficiency of the automatic-start polyphase induction motor is substantially the same as for shunt or a compound-wound direct current, a polyphase slip-ring motor with resistance in rotor starting and a single-phase repulsion-start induction motor. In all sizes this type of motor may be started by closing the switch without the use of a starter as it takes not over 300 per cent of full-load current and has a static torque of about 250 per cent of full-load torque.

# Additions and Extensions During 1923 Estimated at $602,143,000

### "Electrical World" Survey Indicates that 2,890,400 Kw. Will Be Added to Generating Plants by Central-Station Companies—Value of Extensions to Distribution and Transmission Systems Estimated at $318,330,000



VALUE OF PROPOSED ADDITIONS AND EXTENSIONS DURING 1923 EXCEEDS ONE-HALF THE TOTAL GROSS REVENUE FOR 1922

A HIGH degree of expansion in an industry is an excellent indication of prosperity in that industry. When expansion follows a period of general industrial depression and takes on the attributes of high records, then general conditions in that industry may well be considered as of the highest order. Such are the conditions to be found in the electric light and power industry at the beginning of 1923.

Ever since its birth in 1882 the industry has spent annually an always increasing amount for additions and extensions to take care of the constantly growing demand for electrical energy. During the recent period of high prices and high cost of money it was financially impossible for the central generating and distributing companies to make any but the most necessary extensions and additions to equipment. With the recession of exceedingly high costs and the possibility of once again borrowing money at a reasonable rate of interest, the industry has laid plans for record additions and extensions to equipment during 1923. The extent of the large expenditures to be made in the present year is indicated by a survey which has just been completed by the ELECTRICAL WORLD. Returns were received from more than two hundred companies, representing about 70 per cent of the installed generator rating of the country.

The total value of the additions that will be made to the central generating, transmission and distribution systems during the present year is estimated at $602,143,000, which is $278,127,000, or about 86 per cent greater than the estimated expenditures made during 1922, and $387,325,000, or about 180 per cent more than the 1921 expenditures.

The estimated new generating installations during 1923 total 2,890,400 kw., of which 1,987,400 kw., or about 68.8 per cent, will be for steam-electric plants and 903,000 kw., or about 31.2 per cent, for hydro-electric plants. In 1922 it was estimated that 1,772,000 kw. was added to the generating equipment of the central stations, of which about 58 per cent was for steam-

TABLE I—VALUE OF PROPOSED ADDITIONS TO ALL CENTRAL-STATION GENERATING AND DISTRIBUTING SYSTEMS DURING 1923 AS ESTIMATED BY "ELECTRICAL WORLD"

| Section | Steam-Electric Generating Plants | Hydro-Electric Generating Plants | Total Value of Additions to Generating Plants | Transmission Systems | Distribution Systems | Total Value of Extensions to Transmission and Distribution Systems | Total Value of All Estimated Additions During 1923 |

| Totals for United States | 901,500 | 1,028,000 | 1,987,400 | $49,858,000 | $100,543,000 | $209,417,000 | 350,200 | 744,000 | 903,000 | $45,808,000 | $63,790,000 | $74,396,000 |

electric plants and 42 per cent for hydro-electric plants, while in 1921 it was estimated that only 1,251,000 kw. in generator equipment was installed during the year, of which 72 per cent was for steam-electric plants and 28 per cent for hydro-electric plants. The new generator installation in 1923 will, therefore, probably exceed that of 1922 by about 63 per cent and that installed during 1921 by about 131 per cent.

It must be borne in mind in studying these data that the estimates are for additions to generating and distributing systems which were operating prior to Jan. 1, 1923, and do not include the systems of new operating companies organized during 1923, the expenditures of which are, of course, impossible of computation at the present time.

### Value of Steam-Electric Plant Additions More than Double that in 1922

The returns received from the survey indicate that the value of the proposed additions to steam generating plants during 1923 will total $209,417,000, or a little more than twice the expenditures estimated in connection with this type of plant during 1922 and more than four times the steam-plant expenditures in 1921. The rating of the new generators to be installed in steam-electric plants during the present year is estimated at 1,987,400 kw., which is about 93 per cent over that estimated for 1922 and about 120 per cent over the 1921 new generator installation in steam-electric plants. No relation, however, can be said to exist between the value of the additions to steam-electric generating plants and the kilowatt rating of the new generators to be installed. Many companies reported extensive expenditures for new buildings, boilers, stokers, switches and protective equipment without any increase in the generator equipment.

While the net investment involved in hydro-electric projects in course of construction under licenses from the Federal Power Commission totals about $202,300,000, it must be remembered that that figure includes the cost of transmission systems involved in these developments and also that only a portion of this new development will be completed during the present year. Returns received in the ELECTRICAL WORLD survey indicate that during 1923 about $74,396,000 will be spent for new hydro-electric plants or additions to old plants, exclusive of the cost of transmission systems leading from such plants. In 1922 it was estimated that $63,790,000 would be spent in hydro-electric development, and in 1921 $45,808,000. Though the value of additions to hydro-electric plants appears to have increased yearly, yet the rate of increase is materially below that reported for additions to steam-electric plants.

The total value of extensions to the transmission and distribution systems of the country during 1923 reaches the high figure of $318,330,000. Extensions to transmission systems will total about $125,200,000, which is about fifty million dollars over the estimated value of the 1922 extensions. The estimated value of expenditures for extensions to the distribution systems of the country reach $193,130,000, or about two and one-third times the estimated value of extensions to distribution systems during 1922. These record-forming proposed extensions to the distribution systems of the country are probably the most indicative to be found in the accompanying tabulation. The crux of central-station operations is the ultimate consumption of the generated energy by the consumer. The record extensions to distribution systems reported from every section of the country are clear indicators of the extent to which the electric light and power industry is weaving itself into the domestic and economic fabric of the nation.

The North Central States lead in total value of proposed additions and extensions during 1923 with $206,180,000, of which 45.2 per cent will be spent for extensions to transmission and distribution systems and 54.8 per cent represents the value of additions to generating plants. The Middle Atlantic States and the Pacific States follow with $186,200,000 and $95,010,000 respectively. In the case of the Pacific States almost 60 per cent of the total expenditures is for extensions to transmission and distribution systems, this item totaling $56,720,000.

# The Hope of Reward

By L. R. NASH
*Stone & Webster, Inc., Boston, Mass.*

SOME years ago the writer had on the walls of his office an old saying to the effect that "People who do what they get paid for generally get paid for what they do." This is an apt characterization of one of two classes into which those who toil either with hands or brain may be broadly divided.

The first class includes those who hold that the world owes them a living and that they are justified in giving the minimum in hours or effectiveness of work that will insure the holding of their jobs. The second class, with broader vision, holds that in the long run diligence and efficiency will be rewarded and that each day's work should embody the maximum of accomplishment or plans for future achievements.

Few of us realize the extent of individual responsibility for the world's welfare. We may admit that this welfare is measured by the total productivity of all industry, but we are apt to measure this total in terms of inventive genius and the ever-expanding application of machinery to even the simplest of daily tasks.

No one will deny that during the past generation the world has made its greatest progress in labor-saving devices, and yet the appalling fact remains that during that period there has been no appreciable increase in the per capita production of commodities useful in maintaining human life and comfort. This almost unbelievable situation has, by very careful statistical analysis, been shown to exist in the United States, and no other country in the world has shown greater application of machinery to industrial processes.

What is the reason for this stagnation in productivity after centuries of rapid progress? A searching study of the situation, however important and even imperative it may be, is not appropriate herein. Certain of the reasons, however, are obvious and are within the scope of this discussion. The period in question has witnessed a steady reduction in hours of daily labor. At its beginning ten hours or more was common practice. Now eight hours is fairly well standardized, and the workers in a few industries regard six hours as their goal. Certain trades have adopted the habit of school children by working only five days a week.

### *Reduced Working Hours Decrease Productivity*

A reduction from sixty to forty hours of work per week is in itself sufficient to counteract a vast increase in productivity through use of machinery. But curtailment has not stopped there. The units of work per day or per hour have also been subject to drastic and artificial restrictions in many industries, as have also the kinds of work a particular individual is permitted to do. Coincident with these tendencies have come higher rates of wage and standardization of wages without definite recognition of wide ranges in skill within a particular industry.

The inevitable effect upon industry as a whole has been to increase costs of production. A part but not all of this increase has been offset by the use of machinery. For more than twenty-five years there has been a steady upward movement in prices, independent of the war increases. Those whose productivity has been curtailed, as well as others, have had to meet this increase, and they have, therefore, shared in the consequences of their own acts. Few thinking people now deny that reductions in hours of labor, manual or mental, have been beneficial to industry generally, as well as to the individuals directly involved, to the extent that efficiency and productivity have been increased; nor will it be denied that labor in many cases deserved an increased proportion of the value of the joint products of labor and capital. It is the arbitrary reductions and restrictions, benefiting neither industry nor individuals, that deserve unrestrained criticism.

The effect of restrictive methods upon the individual is more far-reaching than its drain upon his pocketbook. It does not take more than ordinary intelligence to recognize the dishonesty in accepting a day's pay for work that might be done in a half day, nor to see that a standardized wage is an averaging process under which the skilled workers help to support the incompetents. A competent worker thus restricted knows that his abilities are wasted, for not only does their full exercise, if permitted, bring him no more pay but it even draws out the reproaches of his less skilled fellow workers against such a proof of their own shortcomings.

In short, the tendencies of the day toward standardization and co-ordinated efforts are destructive of the highest moral standards and efficiency and of that individual incentive which is necessary for both. Any person working without stimulus or hope of reward beyond a fixed standard stipend is a drifter upon life's troubled waters and may become a dangerous derelict.

The proponents of collective methods and standardization claim that the gains which have been brought about justify the individual sacrifices which have been made. A careful study of wage history fails to disclose these alleged gains, but shows, on the contrary, that individual bargaining has brought greater gains in income than collective bargaining. Individual incentive with its hope of reward, contrary to popular impression, has proved more powerful than collective action without such incentive and hope. And this is as it should be; for, if our cherished American standards and traditions, so often praised and defended, mean anything, they mean a maximum of individual freedom and full opportunity for advancement financially, politically and socially.

---

THE foregoing comments, applicable broadly to all kinds of human activities, are merely the preamble or text for the real point of this paper. A rule that works well for individuals is apt to work equally well for groups of individuals. If a hope of reward serves as a desirable stimulus to one man, it will have a similar effect upon a business in which the energies of a number of men are combined. Business is very sensitive to opportunities for profitable expansion, as it is also apprehensive of possible burdensome restrictions. If the profits from business undertakings are in large part taken from the owners through taxation, or are kept within closely prescribed limits, the incentive for ventures into new fields and for aggressive developments and refinements in existing activities is destroyed. It matters not that such new activities might be of great or even revolutionary advantage to the world through new processes or commodities or lower costs of existing ones; the attendant risks will not be taken without the possibilities of unfettered commensurate reward.

In the pioneer days of steam railroads lines were pushed out into or through vast uninhabited areas in the hope that, after the inevitable years of losses, a liberal measure of compensating profit would follow. Why has railroad building in the United States virtually ceased during the last generation? Not because all actually or potentially productive sections have been reached, but, rather, because the undiscerning hand of regulation has withdrawn the possibilities of reward which alone appeals to hardy, adventurous spirits. A return of not more than 5 per cent upon investments in uncertain ventures has no appeal to a prospector who scorns the placid security of a savings bank.

Illustrations might be multiplied, almost without limit, of the steady encroachment of restrictive regulation in the field of commerce and industry, accompanied in most cases by withdrawal of incentive for aggressive activity, and followed by a spiritless conservatism which no longer seeks or expects anything more than conventional compensation for a standardized product. Progressive business, as well as red-blooded American citizens, will not be satisfied with such stifling of their ambitions and hopes of reward. They will either de-

stroy the unwise restrictions or, failing this, will withdraw to other fields not yet touched by the leveling process. It is to be hoped that the first course will prevail.

This is not a condemnation of public regulation, but only a criticism of certain phases of it in which the phenomena above discussed have been in evidence. Those of us who are engaged in the public utility field have not yet realized the results of the standardization of regulatory methods which is gradually becoming effective. The public service field is still comparatively new, and the pioneer spirit and enthusiasm for progress have not yet yielded to conventionalizing influences. However, if the influences continue, the yielding is inevitable.

A more specific statement with respect to regulatory methods as applied to public utilities is now necessary in order that the corrective measures which this paper proposes may be more intelligently considered. The most common exercise of regulatory powers is in the fixing of rates. The almost universal rule is that rates should be sufficient to cover the cost of the service rendered, including operating expenses, taxes, depreciation and a reasonable return upon the fair value of the property employed in the service. It is customary to accept actual operating expenses and taxes and perhaps retirement annuities, if or when they have been shown to be reasonable.

### Operating Efficiency Deserves Recognition

When, however, the value of the property and the proper rate of return thereon are considered, the commissions are apt to abandon specific inquiries and adopt a standard procedure. For example, a uniform return of 8 per cent may be declared reasonable, at least for utilities of a particular kind, without due regard for the risks of the particular enterprises and the efficiency with which its operations are conducted. Operating ratios of public utilities may differ by as much as 25 per cent under apparently similar conditions; the return demanded by investors may vary an even greater amount. In either case the difference may be due, in large part at least, to business skill or the lack of it in the management of the properties. It does not seem reasonable to permit widely different rates for different utilities when the entire difference may be due to varying skill in the construction or handling of the properties. Under competitive conditions no such variation in charges would be possible, for the business under higher rates would soon disappear.

Under regulation, which is merely a means of securing competitive results in monopolistic business, such differences could be adjusted by establishing a reasonable standard of business skill, presumably materially higher than that of the least efficient company and assuredly lower than the most efficient. A premium for efficiency and a penalty for inefficiency would thereby be created, serving a very useful purpose. Both penalties and premiums would lead to better results, with the weight of advantage in favor of the premiums. Without them there is lacking a natural, sustained incentive for improvement. Public utility executives will not in the long run make strenuous efforts to improve and expand their service if all the benefits derived therefrom are taken away from them and given to others. Why should they worry about lower cost and greater volume of business which do not add to their profits? Eighteen holes of golf on pleasant afternoons will prove much more interesting to them than saving a tenth of a pound of coal per kilowatt-hour for the benefit of their patrons.

That this principle is of broader application may be seen in an assumed case of a reasonably efficient street railway of the conventional type. An investigation shows that by the purchase of one-man cars the service of this railway can be improved and operating expenses reduced enough to pay a return on the added investment and provide a margin to amortize the investment in superseded two-man cars. If the proposed change in cars were made, a rate case might be brought and a finding made limiting operating costs to the new basis and the rate of return to the conventional amount on the "used and useful" property, excluding the unamortized superseded equipment. Surely with such possibilities there is no incentive to give better service, but, rather, a risk of serious loss.

If the above illustration is considered as extreme or unusual, a simpler and more conventional one may be substituted. Our assumed street railway, after strenuous past efforts to raise its power-station efficiency to the maximum possible limit, with no heat unit escaping without the closest scrutiny, may awaken to the fact that the kilowatt-hours so zealously produced are being handled rather carelessly after they leave the switchboard. It may find that, through a moderate investment in power-measuring devices on its cars, it can save 10 to 20 per cent of its entire station output. But the installation of these devices calls for some new money and also for a clerical and supervisory force which, if results are to be accomplished and maintained, may disturb the peaceful routine of some of the veterans on the front end of the cars and cause other annoyances. Why bother with the thing at all if the savings are all passed along to the other fellow? These and other more routine refinements in operating costs offer no advantages to the utility if they are to be wholly passed along to patrons through rate reductions as soon as they are discovered.

One more illustration, in this case from actual experience, may be cited to make clear the broad application of this principle to public utilities. Not long ago a large company became convinced, after careful investigation, that welfare activities and a program of death and disability payments would be a good investment through the increased efficiency and improved morale of its employees that would follow. After the company had spent considerable money in studying the plans adopted by other companies and in working out its own plans in the light of the most successful experience elsewhere, but before putting them into effect, its rates were the subject of an investigation by the public service commission. In its findings in the case the commission excluded from the cost of service all charges relating to the proposed welfare and pension program on the ground that such expenditures should not be reimbursed by customers unless or until the program had been put into effect and had proved profitable. It is not hard to forecast the policy of other utilities under the same jurisdiction with respect to such matters, however helpful they might think the final results would be to company, employees and public. With their own initial investment in jeopardy and no ultimate financial gain possible, the unanimous verdict would be "nothing doing."

The situations here illustrated are perfectly analogous to that of the individual who is assured of a standard wage so long as he renders reasonable service. In either case service would be better or greater if the reward were in proportion to the effort and ability to serve. The remedy in the case of the individual is simple in principle, although it involves practical difficulties of application. A suitably adjusted reward for business administration of a high order is not so simple in principle, although it has possibly fewer difficulties of actual application.

A number of regulatory commissions have reduced the authorized return upon public utility property as a penalty for mismanagement or inefficiency. A few others have commended unusual administrative ability as being worthy of reward but have not put the reward in tangible form. The suggested method of award has usually been a higher rate of return, and this appears in imperfect form in several service-at-cost franchises and in the so-called "sliding scale." A greater refinement in this factor might include the value of the property on which the return is based, with particular reference to the basis of valuation and certain intangible elements which are often subjects of controversy. Another real incentive would be found in the establishment of a standard of operating cost, the savings under which would belong wholly or in part to the utility.

The difficulty attending the practical application of such an incentive program lies in the exceptional ability, good judgment and intimate knowledge on the part of the regulatory bodies required for its equitable adjustment in each of the many and diverse cases which would arise. One of the state commissions* has recently developed an interesting system of grading public utilities. This system, which furnished the original motive for this paper, sets up an extended list of factors and elements which are concerned in the furnishing of satisfactory service to the public. The items are given varying weights, depending upon their importance, in determining the final standings of the various utilities. The system has the imperfections to be expected in a pioneer effort of its kind, and the purposes of the grading have not been disclosed. It is doubtful if any system of rating can be devised which would even approximately measure the over-all excellence of a complex business. The more complications are encountered, the less opportunity there is for helpful application of rules and formulas and the greater the need of broad, unrestricted judgment.

### MERIT SYSTEM NEEDS CONSIDERATION

In spite of these fundamental limitations to a rating or merit system, the increasing need of it in the public utility field justifies a most careful study of its possibilities by all regulatory commissions and its tentative application at an early date. Regulation is still in its development stage and the commissions have much to learn from the results of their past practices before a stable, consistent policy can be established. With due deference to the earnest efforts of the commissions to deal justly with both public and utilities, it is submitted that too many restrictions have been placed upon values and returns thereon in rate cases. This element in the cost of service amounts ordinarily to from one-fourth to one-third of the total cost. A variation of 10 per cent in this element has a negligible effect upon the bulk of the utility's patrons. For customary individual or home service it would amount to less than 10 cents per month. On the other hand, this difference may in the aggregate mean to the utility good credit instead of inability to meet all capital needs, liberality in making service extensions instead of delays and restrictions, satisfactory and reliable service instead of breakdowns and irregularities, and, finally, an incentive to improvements and progress instead of discouragement and stagnation. Surely these differences are worth much more to customers than their trivial cost, and a recognition of this fact by the commissions would be of advantage to all concerned.

An increase in the rate of return by 1 per cent, or even less, in a few merited cases as a reward for earnest and successful efforts to render excellent service, and the recognition of such proceedings as a tentative standard by commissions generally, would go far toward reviving the old pioneer courage and aggressive spirit of the operators and to inspire new interest on the part of investors. Good public utility service is vital to any live community, and it should not be withheld for lack of a reasonable hope of reward.

*The Illinois Commerce Commission.

# Accuracy and Vision Required*

### Quite Often Insufficient Time Is Allowed Engineers in Which to Prepare Estimates Properly—Costly Errors from Too Great Haste

BY A. D. THRALL
Vice-President Minnesota Loan & Trust Company, Minneapolis

WERE I to be asked what I considered the most desirable qualifications in an engineer's report, I should reply, "Accuracy and vision." Have we not sacrificed more to speed in this country than really is necessary? The man who wishes to develop water power wants to do it all at once. The engineer must within a few days have his statistics prepared and in hand. He is supposed to be able to make soundings by guesswork that are absolutely perfect. His contours are expected to be drawn by the naked eye in a few moments. His costs must be estimated and be turned in before he actually has determined where his sand and gravel may be obtained. The proprietor wants to let the contract before the cubical contents of the structure or the general plan are finally determined. Isn't this a mistake? We cannot maintain this lavish expenditure of funds simply for the purpose of cheating time. We acquired the habit during the war. A minute then might have meant a hundred thousand lives, and we weighed lives against money, with the balance tipping always in favor of the former.

But the war was a lavish devourer of raw materials. It was a spender of men's labor, and there was a depletion of wealth such as never before had been known.

We became accustomed to get results in the shortest space of time, regardless of costs and very often without proper attention to preliminary details.

I have in mind a project where several million dollars was expended on a large power project before it was definitely known just what the flow of the stream had been. (I don't believe that today, years after construction, there are any definite data.) The consequence was that before the project was successful it was necessary

*Part of a recent address before the Engineers' Club of Minneapolis.

to build a large steam auxiliary to produce sufficient power to carry on the enterprise. Only during three or four months a year was the water power up to the capacity of the plant. Here was a waste of many hundreds of thousands of dollars caused by lack of an engineer's report and by accepting insufficient and unauthenticated figures.

We are all acquainted with projects built during the last two or three years that have been estimated on the basis of a dollar and have cost on the basis of two dollars. The usual calm excuse has been that it was the rise in price of commodities and of labor that caused the discrepancy, but the wildest stretch of the imagination could not cause the mere price of commodities to double the cost of a project within the limit of time that elapsed. There was more behind it than that. It was probably the speed at which the project had been planned, the fever under which everybody worked to complete the proposition, which caused many things to be left out of the calculations that, had time been given him, the engineer would have included. So that before we can have the accuracy that we need on the part of the engineer, or the financier, we must have patience on the part of the promoter.

One of the great reasons why it is so difficult just at the moment to get an entirely new project going is because of the uncertainty of the actual figures of cost. The individual investor is very loath to hazard his funds in any enterprise the cost of which is not assured. Before we can effect a complete cure of this condition the engineer must know that he has full time to finish his work thoroughly, so that, barring the slight variance in actual prices, he can figure very closely the cost of a project. The banker, on his part, must feel that the engineer has had sufficient time to insure that the figures submitted are the actual figures and that before the undertaking is completed there will not be added an additional 100 per cent of cost, the avenues for raising which have been closed. When confidence shall have been re-established, then again will the investors' money be available for new developments.

Not only is accuracy an essential, but there is that great intangible gift of vision. We all strive to get as broad a view as possible. To a few men it is given to see in front and behind, but the success of our personal achievement and of the country's commercial development depends upon the breadth of this view. We all know it, we all appreciate it, when we meet it, and we endeavor in every way to develop a broad view individually. It doesn't reside in figures, it is in the human element behind the figures, and when based upon sound judgment developed from reasonable deduction and not as the result of idealistic hopes it forms the basis of the most permanent kind of confidence.

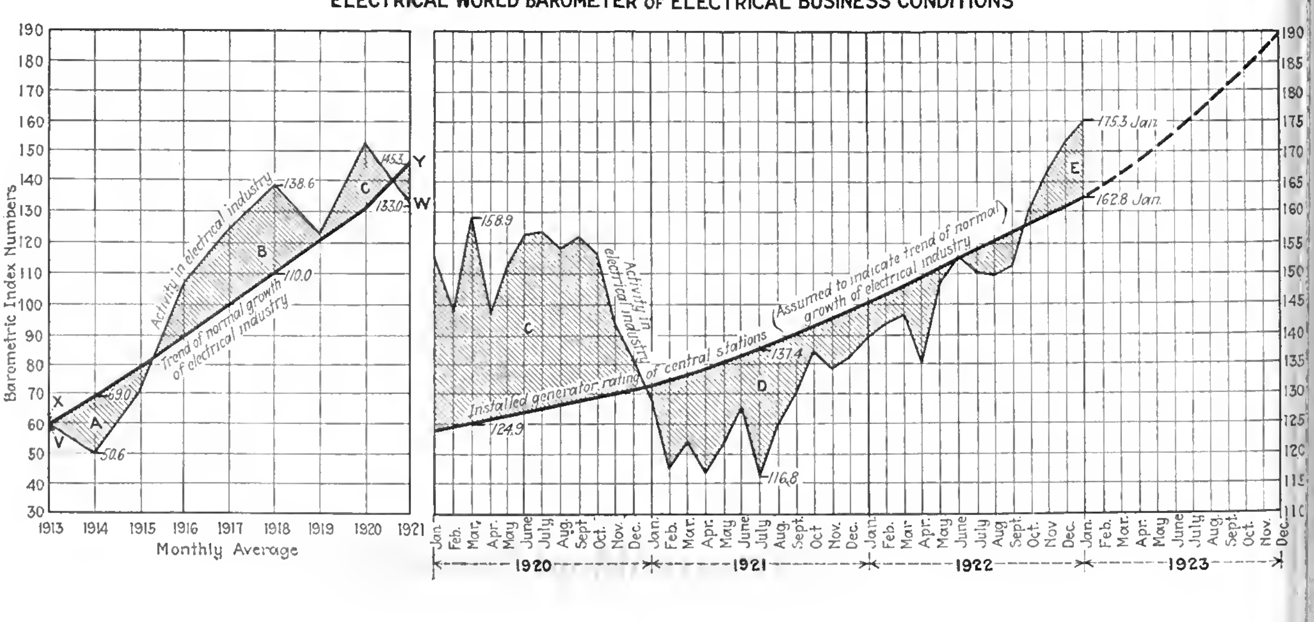
With this friendly interest fully developed, we shall at least make a beginning toward a condition of broader and wiser endeavor along those lines in which we are mutually interested.

## Upward Trend Retarded During January

INDEX figures upon which the "ELECTRICAL WORLD Barometer of Business Conditions in the Electrical Industry" is based indicate that January activity within the industry was in excess of that of December, but that the upward trend was retarded during January as compared with the trend generally experienced by the industry since last September. The basic data indicate an increase of 3.2 points on the barometer scale as compared with December activities. The electrical industry as a whole was in January operating at 12.5 points or per cent above what would have been the point of seasonal demand if growth in the industry had been normal. In December it was operating at 11.2 points or per cent above the point of normal demand.

In its review of general business conditions the Harvard University committee on economic research has the following to say: "Developments in speculation and money during the first month of the year were favorable to the continuance of business advance, although the movements of the curves of our index charts are small. Speculation remains at the same level as in December. Actual commercial paper rates declined under seasonal influences by about the expected seasonal amount. These developments strengthened the probability that the expansion in business activity and the increase in wholesale commodity prices now in progress will be extended through the second half of 1923. With fundamental conditions in the money market unchanged during the next month or two, continuance of improvement in business throughout the year will be clearly forecast."

ELECTRICAL WORLD BAROMETER OF ELECTRICAL BUSINESS CONDITIONS



# Natural Gas as a Fuel for Central Stations

## Unusually High Efficiency in the Burning of Natural Gas Has Been Developed with New Type of Burner—Long Life of Burner and Boiler Settings Are Assured with This Equipment

By E. A. QUINN
*General Superintendent San Joaquin Light & Power Corporation, Fresno, Cal.*

NATURAL gas as a fuel for central-station steam plants has failed to meet with the great degree of favor it should have enjoyed in sections where this fuel is available because of the very poor efficiency and short life of the ordinary types of burner that have been employed. The cost of fuel is the greatest single item of expense in the production of power and ranges from 40 to 70 per cent of the total cost. For this reason and because of the fact that all fuels are slowly but surely increasing in price larger investments in fuel-saving equipment are justified. In localities where a specific fuel is plentiful the problem resolves itself merely into a study of the best methods of burning this fuel. To the engineer efficient combustion means the chemical union of a substance with oxygen at such a rate as to cause rapid increase in temperature without waste. In the new Midway plant of the San Joaquin Light & Power Corporation a burner developed by the engineers of the company is in use which is giving efficiencies of 20,000 to 22,000 B.t.u. of natural gas as fired per kilowatt of electrical energy at the switchboard. This plant recently completed and placed in operation has a capacity of 25,000 kva. It is located near the oil fields of Kern County, California, and is the third plant on the system of this company in which natural gas is burned under the boilers.

### Gas Quality and Pressure Vary

Gas varying from 900 B.t.u. to 1,080 B.t.u. per cubic foot, depending on the location of the wells where it is obtained, is purchased from a local gas company. It is delivered to the plant through a 10-in. welded steel-tube line, guaranteed to withstand a pressure of 500 lb. per square inch. The pressure of the gas delivered ranges from 150 lb. to as low as 7 lb. per square inch in extreme cases. There is no gas held in storage by either the gas company or the power company, and with the exception of what may be taken from the mains by pulling down the pressure there is no reserve to draw on. In this way a small amount of gas can be obtained in case of an interruption to the supply while the oil burners are hurried into action to prevent losing the load on the station. In view of the fact that the gas companies have no storage they desire a constant load and a uniform flow from the wells. Variation in the demand for gas entails a hardship on them and in some cases may injure wells. Flow meters of the orifice type are used to measure the gas delivered. The static and differential pressures are recorded on one chart, from which records the consumption is readily calculated by means of planimeter readings and standard tables. As the gas enters the company's property it is stepped down to 20 lb. or 25 lb. pressure by Chaplin-Fulton pressure regulators and is metered at this pressure.

At the Bakersfield plant there are two sources of supply, and after passing through the regulators the lines continue to the metering stations, where a tie connection parallels them so that the total gas may pass through either or both of the metering lines. In each of these lines there is provided a disk with a 4-in. orifice installed in a flange joint with Wescott differen-

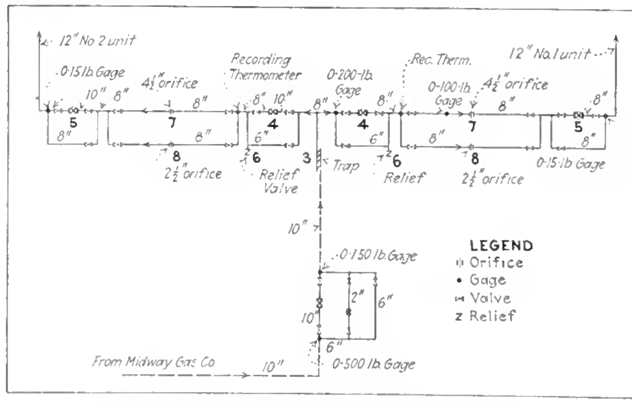


FIG 1—ARRANGEMENT OF METERING EQUIPMENT AT THE MIDWAY STEAM PLANT

tial connections. Meters are operated at their highest rating, cutting them in or out as the demand varies.

After passing the meters the gas is reduced to a maximum of 2 in. of mercury and a minimum of 1½ in., at which pressure it enters the boiler-room header and is passed on to the boilers, being controlled at each boiler by a hand-operated gate valve. Just outside the power house traps are installed to collect oil, water or other residue which may have been carried over from the wells by the gas. These traps are so designed that it would seem impossible that they should not function properly. There are times, however, when the gas carries an oil vapor that will not be caught in any form of trap, and this vapor is carried past the traps and into the boiler-room gas piping and is apparently only given up when the pressure reaches the exceedingly low point at which it is sent directly to the burners. The first two boilers taking gas from the header get the greatest amount of this free oil. Each individual header is provided with drains to remove the oil before it reaches the burner tips.

Samples of gas are brought in twice daily from the Midway steam plant and tested for heating value, or B.t.u. content, and specific gravity. The gas is shipped in bottles made of 4-in. pipe, 30 in. long and tapering to a point at each end, with ⅜-in. nipple and valve attached. The gas is blown in one end and out the other until there is no doubt as to the contents being a true sample of the gas being delivered to the plant. The outlet valve of the cylinder is closed and the pressure allowed to build up to 200 lb. The inlet valve is then

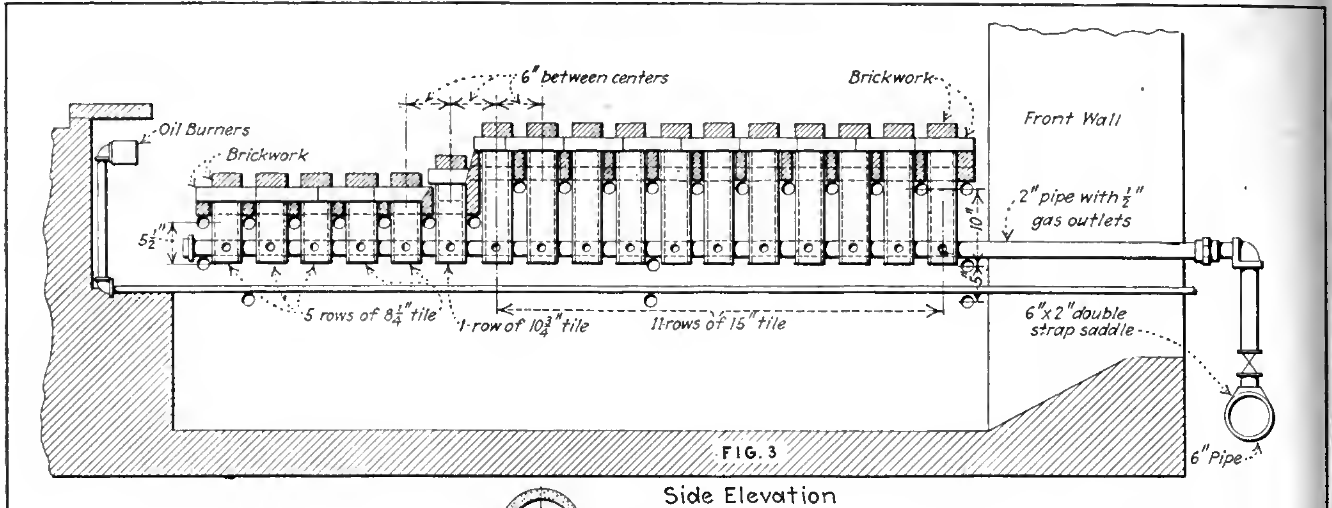
closed and the cylinder immersed in water for the purpose of detecting leaks.

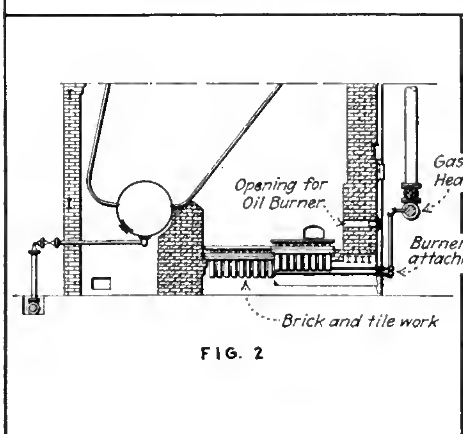
A Humian-Junkers constant-flow calorimeter is used to determine the B.t.u. value of the gas. In this type there is a constant flow of water through the calorimeter and the gas is burned at a constant rate. The temperature of the water at the inlet and outlet of the calorimeter is very accurately read from thermometers calibrated to 0.1 deg. F., mounted with telescopic sights. The gas burned is measured with a very accurate meter of the wet type, and corrections are made for barometer and gas pressure. With these

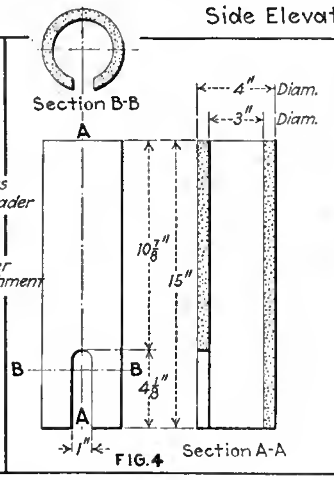
Beaumé fuel oil may be calculated. From this the kilowatt-hours per barrel of oil is figured and used by the operators who are more familiar with the firing of oil to get some conception of the relative performance of oil and natural gas.

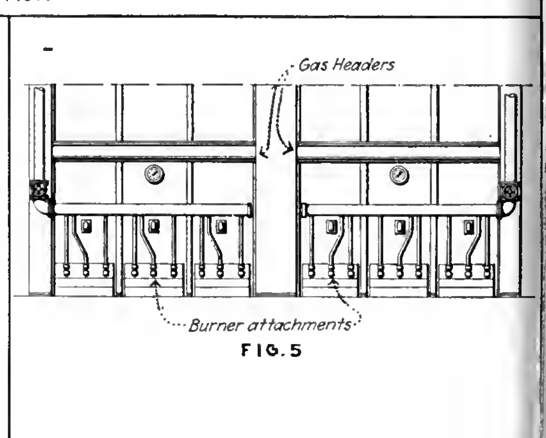
For accurately calculating the gas consumption as recorded by orifice meters, the specific gravity of the gas must be considered as this has a material bearing upon their accuracy. For this purpose an Edwards density balance is used.†

The specific gravity of the gas is the ratio of the total pressure required to balance the beam in air to









DETAILS OF BURNER SETTINGS FOR TYPICAL BOILER INSTALLATIONS

Fig. 2—Setting used with 800-hp. Connelly boiler. Two shutters control the air to the two sections of the combustion chamber. An emergency inlet is provided for oil burners. This is the present and most efficient application of gas burners under boilers.

Fig. 3—Burner setting in class M Stirling boilers. Used before present development was adopted. Oil burners were originally installed in an offset in the bridge wall.

Fig. 4—Cross-section of tile used.

Fig. 5—Front of 825-hp. Connelly boiler with main gas header and pipe feeds to each furnace. In burning gas it is essential that both the air and gas be easily and quickly controlled. In this plant the gas is controlled by the shifting of one lever so that the quantity of gas delivered to each boiler can be reduced immediately should the plant suddenly lose its load.

corrected measurements the B.t.u. per cubic foot is the following calculation:

Temperature rise of water × weight of water ÷ cubic feet of gas used. *

The B.t.u. values of the gas are used as a basis for comparative efficiency data. The total B.t.u. of the gas consumed during a twenty-four-hour period is used to determine the B.t.u. per kilowatt-hour, or the over-all efficiency of the plant. Knowing the total B.t.u. value of the gas consumed, the equivalent barrels of 14-deg.

*There are other corrections which must be made also. One is for the relative humidity of the air. In general this correction is positive up to about 8 per cent humidity and negative for humidity above this amount, varying with the temperature of the air in the room. The other is for the difference in temperature, if any exists, between the room and the water at the inlet, due to the heat that may be absorbed or given off by the body of the calorimeter.

that required to balance it in the gas. The specific gravity of the gas must be accurately determined, as a slight inaccuracy extending over a month's time will mean a large difference in the monthly fuel bill. The beam is brought to balance three times on gas and air and the average of the three readings is taken as a

†This instrument consists of a balance beam carrying a sealed cylinder on one end and a counterweight on the other. The balance beam with its support is mounted in a gas-tight chamber to which is attached a mercury manometer and a small rotary vacuum pump operated by a small motor. The balance case and manometer connections are filled through an inlet needle valve with dry air, and the pressure is adjusted by removing the excess air through another needle valve by use of the small vacuum pump until the beam balances, which balance is ascertained by the observation of the cross line on the end of the beam. After this pressure is determined the balance is evacuated by use of the vacuum pump and filled with gas. The pressure is again adjusted until the beam is in equilibrium, and note is made of the pressure.

basis from which to make calculations. The variations of these readings are very slight, and the use of any one set has been found to be sufficiently accurate for calculation.

### IMPORTANCE OF GAS ANALYSIS

It must be borne in mind that the analysis of the gas is continually changing owing to the variable demand made upon the gas companies for their product and the consequent necessity of cutting in and out of service different wells, each of which produces a gas of different analysis. With gas from different wells it is possible to obtain a theoretical $CO_2$ percentage in the flue gas of from 8 to 13 per cent. All of the gas used at the company's plants contains $CO_2$ ranging from a fraction of 1 per cent to 6.6 per cent, the balance being methane and ethane with minute parts of illuminants. Thus it may be seen that caution is necessary when prescribing a percentage of $CO_2$ as a basis from which to work toward furnace efficiency. Any changes in the gas can be readily detected by the firing of the boilers. The static and differential pressures are recorded by the differential meters, and the temperature of the flowing gas is recorded. Averages for the twenty-four hours are taken of the above pressures and temperatures and with the specific gravity found from test, and, knowing the orifice constant, the cubic feet of gas is calculated. If the gas tests were not made daily, it might work an injustice to the gas company as well as the power company.‡

### NEW BURNER DEVELOPED

The San Joaquin Light & Power Corporation first used natural gas under its boilers at the Bakersfield steam plant in 1911. The first burners installed were of various types. Experiments were made with different burners in an effort to find one which would burn gas economically and at the same time would stand up in service. It was found that patented metal burners were rapidly destroyed, and in an effort to overcome this difficulty the tile burner was developed. At first this was a crude affair as there was no control of the air passing through the tiles, the only control over the fire being by increasing or decreasing the quantity of gas and opening or closing the dampers in the stacks. This original burner gave a very high combustion and high efficiency, and attempts to increase its efficiency by adopting a method of controlling the air through the combustion chamber resulted in an even higher development.

From the accompanying illustrations it will be seen that all air entering the combustion chamber must pass through the burner tiles, and by having a long tile with two baffle bricks over each one a high degree of oxidation is insured. A gas burner to be efficient and economical must have the heat applied properly in the combustion chamber. Gas burners of the horizontal type are likely to damage the boiler foundation and side and bridge walls of the boiler settings owing to an excessive heat being concentrated in certain spots in the combustion chamber. Some burners will not carry boilers at a high rating without causing excessive vibrations or pulsations which can assume dangerous proportions. These pulsations are due primarily to improper mixing of the gas and air which gives incomplete combustion in the form of a series of explosions.

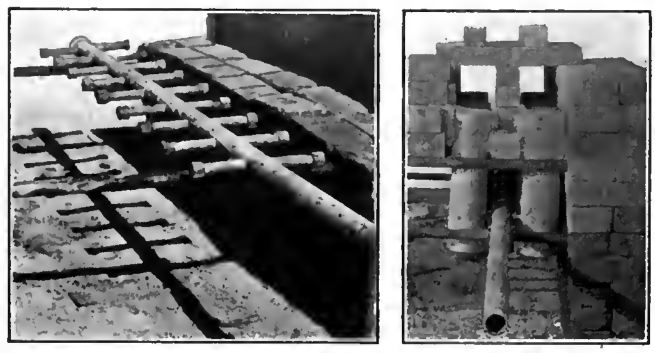
The San Joaquin burner does not have these objectionable features. The load on the boiler can be varied from 25 to 200 per cent boiler rating without back flares. This feature is due to the small gas orifice and the extreme length of the burner tile. Furthermore, the gas is distributed over the entire furnace floor and is not concentrated in the front or at the back of the furnace. The burner tiles are supported by ½-in. pipe nipples and are held in vertical position by shredded asbestos and high-heat-resisting fireclay, allowing perfect freedom for expansion of the tiles. The arrangement and number of burners required for any given installation depends on the width and depth of the combustion chamber and the horsepower of the boiler. Quality of the gas, except in extreme case of an excessive amount of water, has not made any change in the satisfactory operation of the burners which are now being used.

The assistance of C. P. Rhine, designing engineer, and R. A. Wallingford, boiler-room efficiency man, in the preparation of this article is acknowledged.

RESULTS OBTAINED WHEN BURNING GAS

(Based on weighted water tests run on an 825-hp. class M-30 Stirling boiler)

| Boiler Rating (per Cent) | $CO_2$ in Flue Gas (per Cent) | Temperature of Flue Gas (Deg. F.) | Efficiency (per Cent) |
|---|---|---|---|
| 84 | 9.88 | 443 | 84 |
| 110.6 | 10.5 | 518 | 84.7 |
| 139 | 9.8 | 578 | 82.7 |
| 163.64 | 10.64 | 514 | 82.2 |
| 171.2 | 9.3 | 625 | 78.3 |



GAS-BURNER HEADER SUPPORTED BY PIPE AND RED BRICK PIERS AND DETAILS OF FURNACE CONSTRUCTION FOR GAS BURNING

Left—The header is very accurately drilled and tapped so all nipples will be in a horizontal plane. Orifices $\frac{3}{16}$ in. in diameter are drilled in the nipples to permit issuance of the gas. Right—The fire brick wall starts at the burner supports with two courses below the top of tile. Pipe or rod supports hold the tile or burner floor in place. The powdered asbestos cement and fireclay mixed half and half is also supported by the pipes. Asbestos and fireclay are packed around the tiles to allow expansion and reduce breakage. All air entering the combustion chamber passes through the tiles.

‡The following examples illustrate this point: The orifice constant for a 4½-in. orifice in an 8-in. line is 7004.5. Take the differential pressure as 32, static pressure as 21, gas temperature as 68 deg. F. and specific gravity as 0.65. The temperature gravity correction is 0.953; the pressure extension is 33.657; the cubic feet of gas per hour equals 7004.5 × 33.657 × 0.953 = 224,669. The cubic feet of gas for twenty-four hours equals 5,392,056. If the specific gravity had changed to 0.60 with the temperature, static and differential pressures the same as in the above example, the cubic feet of gas per twenty-four hours would be 5,612,736. If the gravity had been taken as in the first case, the plant would have used 220,680 cu.ft. of gas that did not show on the meter. As another case take the specific gravity at 0.70. Other things being equal, the cubic feet of gas per twenty-four hours would be 5,194,932. In this case if the specific gravity had been assumed to be 0.65 and the true gravity was 0.70, the plant would not have used 198,024 cu.ft. of gas that showed on the meter. From these examples the necessity of taking gas samples each day is evident. Assuming that the plant is carrying a load of 10,000 kw. and that the calorific value of the gas is 972 B.t.u. per cubic foot, then in the first of the examples the B.t.u. per kilowatt-hour equals 21,837, in the second 22,731 and in the third 21,035. From this it will be seen that the engineer cannot get a correct report of the number of B.t.u.'s per kilowatt-hour unless he absolutely knows the calorific value of the gas in question.

A Place Set Apart for Suggestions, Comments and Criticisms, to Which All Men of the Electrical Industry Are Cordially Invited to Contribute

## Importance of Cable Engineering

*To the Editors of the* ELECTRICAL WORLD:

I have been impressed many times recently with the lack of appreciation, on the part of young engineers as well as some old ones, of the magnitude and importance of cable engineering as a part of electrical engineering. In trying to find a reason for this, I am inclined to believe that there is at least some fault in the university training of these engineers. I think any one will agree, any analysis will show, that most of the emphasis of electrical engineering courses is on machinery, with some attention to high-voltage transmission, and that cable work is largely neglected.

I think it will surprise some to know that this company spends almost twice as much for lead-covered cable as it does for turbo-generators, and that the investment of this company in overhead and underground lines, including the poles and conduits and manholes, is nearly one-third of the total investment.

A superintendent of one of the large cable factories told me recently of his difficulty in finding a technical man who would devote his time to research work on wires and cables, principally lead-covered cable. In answer to an advertisement he said he had about twelve or fourteen applications, and when these men, who were all technical graduates, were told that the research was to be regarding lead-covered cable, they thought the field entirely too narrow and did not consider it worth their while to undertake such work. Where did the technical graduates get such ideas, and is it not fair to assume that their ideas regarding the narrowness of the field were due in large part to the fact that while they were in the university they received very little information along such lines and performed in the laboratory no experiments or tests on cables? Is it not true that the technical graduate forms his opinion of the relative importance of the various lines of engineering work largely from the amount of time devoted to the various subjects by the professors in their classwork and their lectures, and by the routine experiments or tests which are required of him in the electrical engineering laboratory? And if the technical colleges in their classwork and in their laboratory work devoted an amount of time to the subject of wires and cables in keeping with the importance of these subjects, do you not think that the condition above described would have been reversed, and would not the cable manufacturer probably have had more applications than he could use, instead of being turned down by fourteen men who answered his advertisement?

That particular manufacturer has no occasion for feeling lonesome. There are other manufacturers and utilities that are in exactly the same condition. As you are aware, there have been some tremendous advances in the art of cable manufacture in the past five years, and there is every reason to believe that the present rate of improvement will continue for some years.

The manufacturers that are making the most progress are the ones who have a staff of technical men continuously engaged on research work, and the ones that are making the slowest progress have no men whatever engaged continuously on research work, or perhaps do a little research spasmodically when they are forced into it by difficulties in meeting their guarantees. The last two sentences are not mere theories or ideas, but are statements based upon the records of our tests on cable purchases made in the last four years. We buy cable from all of the leading manufacturers in this country, and we are able to tell from the tests on the cables that we purchase just when a manufacturer makes an improvement in his product and the amount of the improvement. We can also tell from these records, beyond any doubt whatever, which manufacturer is in the lead, and, with a very close degree of accuracy, the relative standing of the leading makers in the art of cable manufacture. Their order shifts a little from time to time, owing to the varying amount of research work that is being undertaken by the several manufacturers.

In view of the facts set forth above, does it not seem self-evident that the regular series of tests offered to the higher students in electrical engineering laboratories should include a few tests on lead-covered cables? Such tests, for example, might be thermal resistivity of the insulation and dielectric loss. If the dielectric-loss curves are taken at a number of temperatures and voltages on a single piece of cable, then these curves will show the ionization loss in the cable. All of these tests could be made on a single piece of single-conductor cable, permanently set up in the laboratory, although it might be more convenient to have the two tests made on two separate pieces of cable. I think that these tests would very likely require the use of instruments and methods of tests which would be entirely different from any of the tests which students are now performing, and if this is the case would not such tests be a distinct addition to the laboratory? And would not the laboratory, with the addition of these tests, give students a better idea of the relative importance of the various branches of electrical engineering than they can possibly get without such equipment?

## Lighting of Hampden County Memorial Bridge at Springfield, Mass.

*To the Editors of the* ELECTRICAL WORLD:

Referring to page 378 of the Feb. 17 issue of the ELECTRICAL WORLD, showing a night photo of the Hampden County Memorial Bridge at Springfield, Mass., which was taken by the writer, I would call your attention to an error which occurred in the description of the lighting.

Your account makes it appear that one 500-watt "Mazda C" lamp was used in each of the four 80-ft. towers in a globe of 2½ ft. diameter. These towers each use four 500-watt "Mazda C" lamps, which are inclosed in a sectional diffusing globe 6 ft. in diameter. Owing to the height of the towers and the characteristic of the globe it was necessary to use approximately five times the wattage in this unit that was used in the ornamental luminous-arc lamps to obtain the correct balance in the lighting effect.

L. O. INGALLS,
Electrical Engineer.
United Electric Light Company,

# Central Station and Industrial Practice

Installation, Operation, Maintenance, Test and Repair of Generation and Distribution Equipment, and Methods of Economically Utilizing Electric Service in Large Industrial Plants

## Cable Rack for Industrial Power House

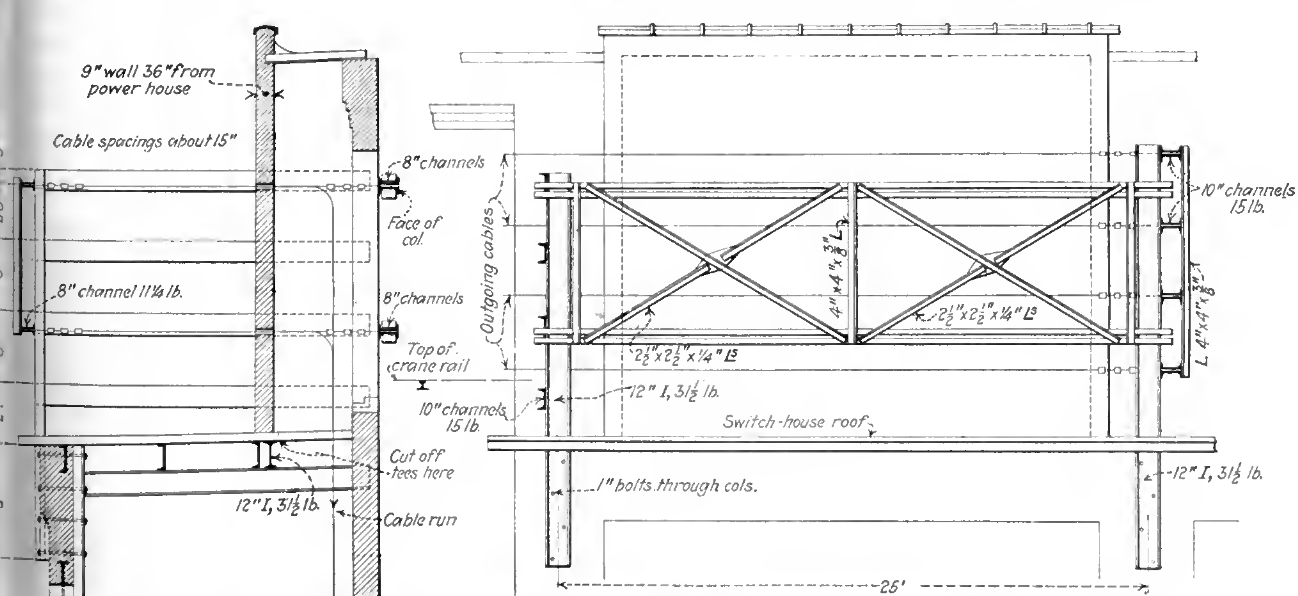
CABLE RACK CONVENIENTLY BUILT ON SWITCH-HOUSE ROOF

XIGENCIES often arise in industrial-plant layouts which involve tensive and difficult changes in ectric power distribution facilities, id too often, it sometimes seems, a pe line or some structural arrange-ents force the power distribution ystem out of its logical and impor-nt position in the industrial-plant ans. No doubt this condition has isen because of the inherent flexi-lity of electric distribution systems compared with the carriers of her forms of energy.

Some time ago a problem presented self during the construction of a rge industrial plant concerning the rangement of outgoing power feed-s from the power house. The origi-l design contemplated the feeders aving the switch house at right igles to the outer wall, but subse-ient location of additional buildings ljacent to the power house left only ie avenue for the power feeders—arallel with and above the switch ouse, which was essentially a lean-to ructure half the height of the power ouse.

Naturally a cable rack above the of then became essential, but running the leads from the interior of the switch house to the rack above presented considerable difficulty. It was not possible to obtain room for an exit on the outer wall of the switch house owing to adjacent structures, and roof bushings are not often desirable for the usual industrial-plant conditions. A solution was found by building a 9-in. "false" wall from the roof of the switch house about 36 in. out from the power-house wall. The roof purlins of the switch house under this wall were reinforced by a 12-in., 31½-lb. I beam. A large steel-frame window in the power-house wall was removed, permitting the placing of channel members as shown in the line drawing to carry the ends of the short transverse cables. The cables from the switching equipment were run vertically along the wall and were spliced to the transverse cables. A short vertical jumper connected the transverse cables with the line cables above and below the transverse cables and running parallel to the walls of the power house.

All dead-end connections were made without the necessity of drilling by arranging 8-in., 11¼-lb. chan-



STRUCTURAL LAYOUT OF CABLE RACK ON ROOF NECESSITATED BY CLOSENESS OF OTHER BUILDINGS

nels back to back with spacers so that a space of 1¼ in. was left between them in order that any size of eyebolt required might be inserted in the slot. At one end of the rack 10-in. channels were provided for attaching steel pins and line insulators.

The transverse cables are horizontal, but water does not run in through the wall bushings as the very slight sag in the cables causes a drip to be formed on the cables outside the false wall 36 in. from power house.

# Extracts from an Operating Code

BY FIELD EDITOR ELECTRICAL WORLD
New York, N. Y.

## Dangers from High or Low Water in Boilers

VERY serious damage may be caused in boilers or to engines or turbines connected to them if the water becomes too high, so that it goes over into the steam main, or if it is too low, causing the boiler to overheat. There are three things that may cause the water level to rise quickly, and that should be very closely watched by the water tender: (1) Increasing the forced draft, particularly when the setting and the water in the boiler are still hot from previous high steaming rates; (2) increase in feed-water pressure, caused by placing an additional feed pump in service or by decrease of feed-water temperature; (3) faulty action of the feed-water regulator.

In case of high water the following preventive steps abstracted from the operating code of the Philadelphia Electric Company should be taken as a typical method for reducing the water level properly:

INSTRUCTIONS TO REDUCE HIGH WATER IN BOILERS

1. Close the feed-water valve.
2. Try the gage cocks to make sure that the water is high.
3. Open the superheater drains and surface blow-off valves, if easily accessible.
4. Cut off the forced draft.
5. Open the blow-off valves.
6. Stop the stoker.
7. Partly close the back damper, leaving sufficient draft to clear the gases.
8. Maintain practically a banked condition and blow down until the water level has been lowered to between two and three gages.
9. If a feed-water regulator is in service, close the feed valve to the regulator and operate the feed valve by hand until the trouble has been located.
10. When normal water level is reached put the boiler in service.

Low water in a boiler may be dealt with under two divisions—one treating conditions where the water in the gage glass is low and can be seen and the other where the water is below the gage glass.

Case 1. When the water level in the gage glass is low it should be brought to normal level by increase in rate of feeding the water.

Case 2. When the water is out of sight and the water tender has no positive knowledge of its level a very dangerous condition exists which may result directly in a disastrous accident, or later in extended and expensive boiler repairs, unless proper steps are taken to remedy this condition at once.

Should water be admitted to overheated drums or tubes, the sudden formation of steam would greatly increase the pressure, which would violently rupture the boiler metal in case it was hot enough to have lost its strength. The least that can be expected would be loosening of the tubes in the drums or headers, caused by the uneven contraction of the boiler metal when the cold water touched the hot surfaces. In this case the fire should be dumped and the boiler subjected to a hydrostatic test. The specific instructions for this operation follow:

WHEN WATER IS BELOW GAGE GLASS TAKE BOILER OUT OF SERVICE

1. Close the feed-water valve to the boiler.
2. Cut off the forced draft.
3. Partly close back damper, leaving sufficient draft to clear the gases.
4. Stop the stokers.
5. Where possible, drop the dump plates.
6. Drown the fire and allow the boiler to cool.
7. As the steam pressure drops, shut the main stop valve.
8. Close the trap-line valve above the automatic non-return valve.
9. Lock the automatic non-return valve.
10. After the boiler is cool, open all vents between automatic non-return valve and the boiler.
11. Inspect the boiler and subject it to a hydrostatic test.

## Induction Motor-Generator with Compensator Start

INDUCTION motors of motor-generator sets without slip rings and external secondary resistance must be protected against excessive starting current by impressing a low voltage on the primary in starting. This voltage is obtained by placing the compensator handle in the starting position. When the machine has reached approximately full speed full voltage is impressed by throwing the compensator handle to the running position. The following abstracted from the operating code of the Philadelphia Electric Company are instructions for operating these sets.

STARTING

1. Close the alternating-current bu[s] switch.
2. Place the compensator in th[e] starting position.
3. When the machine comes up t[o] speed place the compensator in the running position.
4. Close the generator field switch.
5. If the generator is compoun[d] wound, close the equalizer switch.
6. Adjust the direct-current voltag[e] to that of the bus and close the circu[it] breakers and negative and positive machine switches.

SHUTTING DOWN

1. Reduce the load of the machin[e] to be taken off to as low a value a[s] possible.
2. Trip the direct-current circu[it] breakers and open the machine an[d] equalizer switches.
3. Open the alternating-current bu[s] switch.
4. Return the operating handle [of] the compensator to the "off" position [if] it does not return automatically.

## Repairing Flume Without Interrupting Service

FIVE miles of wood flume su[p]ported directly on the groun[d] along level stretches and on woo[d] trestles at gulleys is being rehab[il]itated by the Tennessee Electr[ic] Power Company without taking [it] out of service. The flume, whi[ch] serves the 15,000-kva. hydro-electr[ic] station No. 2 on the Ocoee Riv[er], measures 11 ft. x 14 ft. in cross-se[c]tion and carries 13,000 cu.ft. [of] water per second. The wood ber[ts] supporting the bottoms and sides a[re] being replaced by galvanized-ste[el] bents and the wooden trestle by co[n]crete. The substitute parts are bei[ng] placed between those to be replac[ed] so that the latter can be removed [as] the work progresses. Seven hundr[ed] out of 6,400 bents have been install[ed].

RATE OF CUTTING CAST-IRON PLATES (LEFT), CIRCULAR SECTIONS OF CAST IRON (CENTER) AND SQUARE BLOCKS OF CAST IRON (RIGHT)

## Cutting Metals with the Electric Arc

THE process of arc cutting is purely a melting process, the heat energy of the arc terminal being directed along the line where the cut is desired. Graphite or carbon electrodes are usually employed for this work. In special cases metallic electrodes heavily wrapped with asbestos yarn employing current values higher than normal have been used for cutting, the electrodes being first dipped in water, which forms steam and blows the molten metal away. This method, however, is quite expensive and has been used only to a limited extent by the British Admiralty for cutting deep, small diameter holes in armor plate.

For general cutting work graphite or carbon electrodes are used and current values of 300 amp. to 1,000 amp., depending upon the nature of the work and the cutting speed desired.

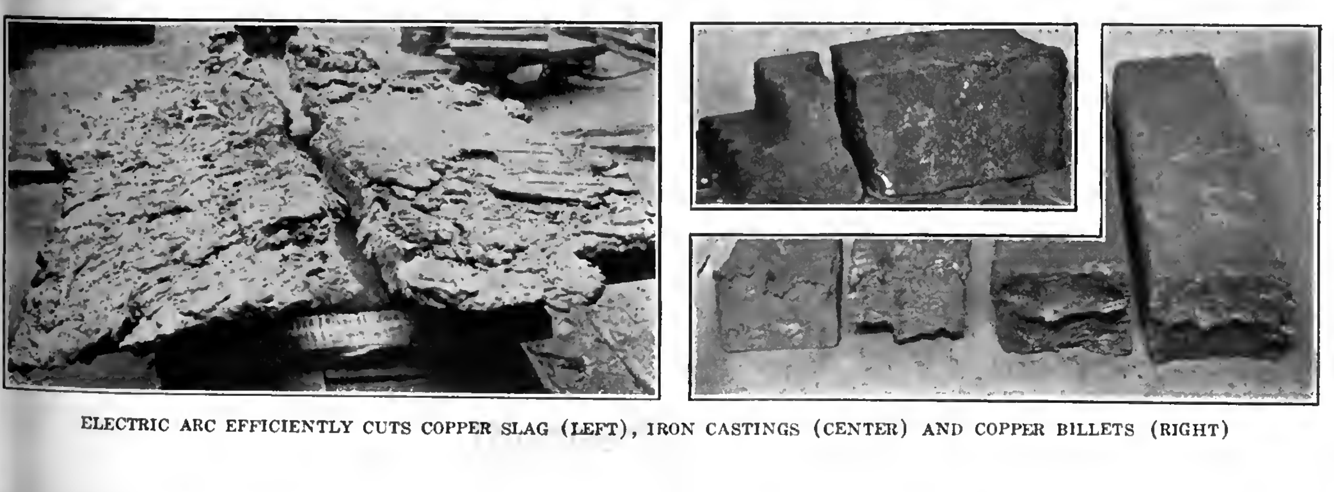
Foundries make use of arc-welding equipment for repairing defective castings and use the same apparatus for cutting off risers and burns from their castings. A riser from a large gray-iron casting was cut through the neck in five minutes' time, using 800 amp., the neck measuring 3 in. x 9 in. The riser was then cut through the main portion, 8 in. x 8 in., in seventeen minutes, using the same current. With labor at 60 cents an hour and electric power at 2 cents a kilowatt-hour for the motor-generator, there would be a cost of 15 cents for cutting the neck and 52 cents for cutting the body of the riser. The speed of cutting castings of several forms is shown in the accompanying curves, using a current of about 600 amp.

Where it is desirable to cut the material to accurate dimensions, it is necessary to lay out a guide line with white lumber crayon which the operator can follow with his arc. It is then possible to make a neat cut in plate steel $\frac{1}{4}$, $\frac{3}{8}$ or $\frac{1}{2}$ in. thick. As an example, a piece of $\frac{1}{4}$-in. plate steel was cut at the rate of 75 ft. per hour, using 450 amp.

Companies will find the arc process by far the cheapest method for cutting rivets and for cutting up steel-plate material into pieces sufficiently small either to be charged directly into the cupola or to be cut up to such size that the pieces may be handled for recutting in a shear. The plate material in these cases is generally heavily covered with paint or rust so that current values of 400 amp. to 600 amp. are frequently used, and in some instances as much as 800 amp. Using this latter current value coal cars have been cut up at an average rate of 75 ft. per hour, an entire coal car being cut up in four hours' time into pieces sufficiently small to be handled by four men who were shearing the material for cutting into charging size. The cost, including labor and power for the motor-generator, was \$6.80.

For cutting the rivets, currents of 400 amp. or 600 amp. are usually used. When using 400 amp., average operators will cut from 1,800 to 2,000 rivets, $\frac{5}{8}$ in. in diameter, per ten-hour day, and some operators will run as high as 2,600 to 3,100 such rivets when the work is on a piece-rate basis. Cutting with the arc is not limited to iron and steel, but can be applied equally well to non-ferrous metals such as brass, bronze and copper. In fact for cutting copper which cannot be cut mechanically the arc process is by far the cheapest to use.

Because of the high thermal capacity and high heat conductivity of copper it is necessary to concentrate the applied heat at a sufficiently high rate to melt the copper before the heat is dissipated in it. To do this cutting effectively it has been found most satisfactory to use a current value of 800 amp. to 1,000 amp.



ELECTRIC ARC EFFICIENTLY CUTS COPPER SLAG (LEFT), IRON CASTINGS (CENTER) AND COPPER BILLETS (RIGHT)

A large piece of copper slag which was originally 6½ ft. wide and 7 ft. long along the central cut had several cuts made. The metal was approximately 1½ in. thick through the sections where the side cuts were made. This was done at a rate of 3½ ft. per hour. The thickness of the metal through the central cut varied from about 1½ in. at the extreme edge to 7 in. at the center of the piece, the average thickness therefore being about 4¼ in. This cut was completed in five hours. A current value of 1,000 amp. was used for all this work The cost on the basis of labor at 60 cents an hour and electric power for the motor-generator at 3 cents a kilowatt-hour is $16.78.

## Safety Entrance Switches with Meter Adapters

INCLOSING service entrances and meter loops has received much consideration during the past year, and many companies which formerly had no specified entrance requirements have adopted some type of combination safety entrance box. The benefits derived from this type of entrance are evident. They include a decrease in fire hazard over open meter loops, the prevention of tampering with the meter as all wires are inclosed and sealed between service brackets and meters, and the improved and more uniform appearance of the meter installations. Companies which have adopted certain types of switches have had minor problems to solve arising from the peculiarities of the type of switch, while others are attempting to solve the same problems before announcing their requirements.

The following questions no doubt have confronted many companies and have led to varied solutions:

1. Will the extensive use of entrance switches and keen competition between manufacturers develop a more practicable switch than is now on the market?
2. Is it good policy to specify one particular type of switch?
3. If a particular make of switch is not specified, will meter installations become a hopeless assortment of different types of boxes, causing much trouble and expense in changing meters and testing and also resulting in the electrical contractors using the cheapest box procurable?
4. Which should furnish the meter adapter, the central station or the consumer?
5. Are testing devices essential, and, if so, who should bear the expense?
6. Should the box be so constructed as to permit the renewal of blown service fuses by the customer without breaking the seal on the box?
7. Has the company a legal right to seal a switch box owned by the consumer?
8. If the service fuses are sealed: (a) Shall the consumer be required to place an additional set of fuses on the load side of the meter, when there is only one circuit in the house? (b) Should the customer or any electrician have permission to break the company's seal to renew service fuses? (c) Who should bear the expense of renewing the service fuses?
9. If the service fuses are accessible to the customer: (a) Will a fire hazard often be created by improper fusing or cutting out of fuses when none are available at the time of blowing? (b) Will the assurance against theft of energy be decreased?
10. What type of fuses shall be specified for the service, plug or N. E. C. standard?
11. Will older types of meters have to be junked for lack of suitable adapters for them?
12. Should the combination entrance box be required on previously wired installations when these are reconnected?
13. Does the expense to both consumer and central station justify the requirement of this type of entrance?

In adopting a standard entrance box it is essential that the box be rugged in construction, simple in operation, plainly designating the "off" and "on" positions of the switch, equipped with some device which will facilitate testing without removing wires from the load side of meter, and at the same time afford means of supplying electricity to the premises by conveniently shunting the meter. If more than one box is approved, the meter adapters should be interchangeable, or else difficulty will be encountered in changing the type of meter at an installation where the type of box is not the same. It will also cause an undue investment on account of having to carry in stock an assortment of adapters for each box.

It seems plausible that sooner or later some standard specifications in the manufacture of these boxes must be adhered to, and it is up to the central stations to specify this standard and avoid the use of the irregular designs before their lines are crowded with boxes which will eventually be objectionable. A good combination box is an asset to both the consumer and the central station, but a poorly made and designed meter entrance box is far worse than none at all.

## Repainting Towers with Conductors Alive

OWING to the fact that the Tennessee Electric Power Company has no loops or duplicate circuits in most parts of its system, it is repainting its black-steel towers while the circuits are "alive." Around the conductors and in the other hazardous portions of the tower this is being accomplished by using paint brushes attached to insulating wood poles like those used in live-line insulator changing.

METER ENTRANCE BOXES MUST BE RUGGED AND PROVIDE SUITABLE MEANS FOR SHUNTING AND TESTING

# The Stoker Problem Discussed from an Operating Viewpoint*

THE mechanical stoker regarded as a unit is one of the most reliable pieces of apparatus in station equipment provided that it is worked continuously and is operated and maintained intelligently. This statement is qualified because it is felt that there is room for improvement in design to provide against undue depreciation of the stoker while in a banked condition and to insure that it is not put out of commission during the banked period or while bringing it from "banked" to "steaming."

With regard to the subject of maintenance, there is still a chance for further improvement. Particular reference is made to those parts on the stoker where the wear is greatest, emphasizing that the construction be made so that these parts can be renewed separately.

In discussing the efficiency of the stoker the auxiliaries which the stoker imposes are also included. If inefficient auxiliaries are required, then the use of them must be charged up against the stoker.

### Factors Controlling Efficiency of Stokers

In using the stoker efficiently the operator is bound by limitations of design over which he has no control. He has a definite load to maintain, and if this is maintained efficiently, a definite amount of coal is required. The size and distribution of the air holes in the grates and the grate area are fixed quantities for the operator. These two items should be so accounted for in the design that, for continuous operation at uniform rates, a fuel bed can be maintained of such shape and thickness that the proper amount of air will pass for the efficient burning of the coal and that the coal will approach 100 per cent combustion before reaching the grinder pit.

It is realized that the designer cannot design the furnace to meet uniform conditions of service and at the same time produce a furnace for wide and rapid change in the rate of forcing without some sacrifice of efficiency. However, the design should be such that the change can be made without undue throwing of the coal by the air, so that the contour of the fuel bed may be brought back to give efficient operation.

*Extract from an address before the Stoker Manufacturers' Association.

It is generally conceded now that it is not feasible to operate the clinker-removal system continuously in synchronism with the stoker drive but that it is better to adopt a policy of intermittent operation in order to allow for variations of ash content in the coal and for the different rates of forcing the stoker. There is one objection to this method of operation: As the grinder always removes the refuse faster than it is made, the responsibility for keeping the clinker grinder from burning out is left to the operator. Hence it has been found desirable to speed the grinder up to a point where it is only necessary to operate it a few minutes out of each hour.

### Design of Clinker Crushers Claimed to Be Wrong

A fallacy in design that has done more to discredit the clinker grinder than any one other thing is the usual shape of the grinder pit. When the coal reaches the clinker pit it is nearly all ash, and there is then very little decrease in volume. However, almost invariably the clinker pits are designed with decreasing volume as the ash proceeds on its way. This particular mistake in design is causing a large part of the trouble met with today with clinker grinders.

While discussing the coal feed, it should be pointed out that the same mistake is made as in the grinder pit. Why decrease the size of the hopper as the coal feeds down closer to the ram? Agitation would be needed in few cases if the hopper were properly designed.

If the variable forced-draft fan does not prove possible, other things considered, then a compromise ought to be made by running several fans to a common duct serving several boilers and by arranging to take fans out of operation in order to maintain the desired conditions. By following this method the efficiency will be impaired only when the pressure is not carried at an economical point for the given speed. The delivery of air per fan can be maintained approximately constant and therefore efficiently.

The cost of operation of stokers is affected both by the design and by the method of operation. The admission of air through the brickwork of the side walls and side air boxes has done much to cut down cost of operation as well as maintenance owing to absence of clinkers. The increasing amount of air added above the fire, however, will have to be taken into consideration in the design of the stoker when its use is extended to other parts of the furnace, as is the tendency in new layouts.

The designer of the stoker should do everything that is possible to reduce siftings. The accumulation of siftings not only increases operating cost because of the labor of removing but also by the moral effect on men working in untidy surroundings.

With the improved method of operation and the improvements in the design of the stoker that have been made, the labor of operation has been reduced to a minimum, and today 60,000 kw. is being produced with three men, two of these being rated as water tenders and stoker operators and the other as greaser and oiler and general utility man. The stoker has been brought today to a degree of perfection where there is no advantage from the labor standpoint in burning oil.

### Heating Feed Water by Bleeding Main Turbine Units

Perhaps it would not be out of place to speculate on changes in stoker design which will have to be made in the future in order to keep pace with changes of methods in other parts of the plant. The particular thought in mind is the change of sentiment with regard to the source of heat for feed water. The latest ideas on the subject among engineers who have made a study of this problem is to bleed heat from one or more of the stages of the main turbine in addition to what may be obtained from steam auxiliaries and house-turbine sets.

This method is making the installation of economizers harder to justify in large power plants. The heat from the flue gases, however, cannot be wasted; therefore preheaters will be forced into use, and apparatus for this purpose, which is now effectively in use abroad, will undoubtedly be introduced into this country. When this becomes an accomplished fact and air is being delivered to the boiler at 200 deg. or 300 deg. F., there will be need for redesigning grate air-flow passages to meet the new requirements in order to maintain the present good results in maintenance.

**Advertising, Selling and Service Methods**
**Commercial Organization and Management, Customer and Trade Relations, Public and Financial Policies, and Reports of Company Plans and Experiences**

## Hazards of Amateur Radio Antenna

THE sub-committee on radio of the accident prevention committee of the National Electric Light Association, has recently reported on twelve fatal accidents caused by radio enthusiasts coming into contact with light and power circuits when installing aërials or working with radio conductors. The committee calls attention to installations being made by youngsters and laymen which were heretofore made only by experienced linemen.

A serious aspect of the situation is the fact that the accidents are due entirely to ignorance and are of a character which regulation cannot reach because the damage is done before the authorities who must administer regulatory measures are aware of what is going on. Court penalties are therefore ineffective. The committee has called attention to some of the educational work done by central stations in sending out bill stickers and by the use of newspaper advertising, talks to school children and in some cases warnings and information broadcast over the radiophone itself. The following points have been compiled by the committee from data used by a number of companies in such educational work:

Never pick up a wire lying on the ground or dangling from a pole. The wire might be alive, that is, charged with electricity to a dangerous degree. Report fallen wires immediately to the police department or power company.

Never climb a pole to which wires are attached. They might be in contact with high-voltage wires and consequently dangerous.

Never string wireless aërials over or under any other wires. Should these two sets of wires come in contact with each other, the aërials might become dangerously charged.

Never attach radio aërials or anything else to poles carrying wires of any sort. Accidental contact with live wires may cause injury or death or bring about fires.

Always attach aërials to substantial supports so located that if either the support or aërial wire breaks it cannot come in contact with other wires.

Remember that it is quite practical to operate a radio set with an indoor aërial.

Do not use kite aërials.

Do not attach antennas to chimneys. Chimneys were not designed for such purposes, and you might be down below when the bricks start falling.

In the interest of public safety the company is forced to forbid the attaching of any radio aërials to its poles and to insist that no radio antennas be strung above its power distribution wires.

The committee also made the general recommendations that amateurs should not be allowed to attach aërials to poles or towers carrying electric light or power wires and that surveys should be made and aërials in hazardous locations, insecurely fastened or supported, should be condemned or removed. The central-station companies should co-operate with those installing aërials and when practicable supervise their erection. Indoor aërials are recommended where practicable, and care should be taken to see that storage-battery and rectifier sets are properly installed as to both electrical and fire hazards. It was also recommended that reliable information as to radio hazards and prevention methods should be given adequate publicity. This information should be widely distributed through newspaper men, superintendents of schools, and to the general public by talks, newspaper advertising, stickers on customers' bills and other available means.

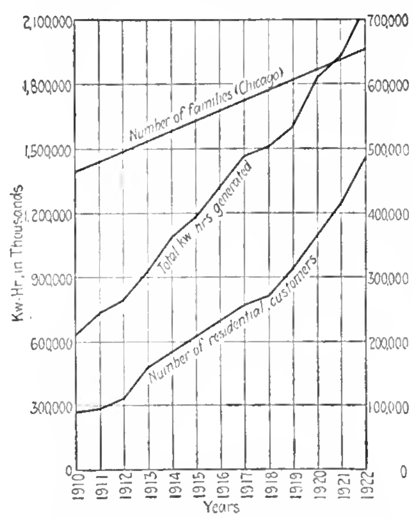
## Boston Edison Forming Boys' Club

TO INTEREST boys of ten to sixteen years who are related to its employees, the Edison Electric Illuminating Company of Boston is forming an "Edison Light Boys' Booster Club," under the direction of L. D. Gibbs, superintendent of the advertising department. A letter has been sent to all of the company's employees with the object of ascertaining the probable field of activity to bring the rising generation into closer contact with the business of producing and supplying electricity. It is expected to develop a self-governing organization and to include visits to plants and other "doings" of interest to boys in the company "family."

## Twelve Years' Growth of Electric Service

THE accompanying diagram shows graphically how the number of residential customers on the lines of the Commonwealth Edison Company in Chicago has increased during the last twelve years. This increase has been much more rapid than the increase in the number of new families in the city.

Since 1910 the number of families



INCREASES IN CUSTOMERS, NUMBER OF FAMILIES AND KILOWATT-HOUR SALES

has increased less than one-half, while the number of residential customers of the Edison company has increased over four times. The chart shows that the territory is far from the saturation point as there are still about 157,000 families in Chicago who are not now being supplied with electricity. This fact provides a large field for expansion of the company's business.

In addition, commercial and large industrial users of electricity are constantly being added as customers. One of the greatest factors in increased business of the company, as reflected in the curve showing kilowatt-hour sales, is the increased use of electricity by the existing customers. The home is rapidly becoming electrified, greatly relieving the housewife of physical labors, and electricity is being put to more widely diversified uses as respects both power and light.

## Installment Bonds Used to Finance Rural Lines

AN INTERESTING method of financing rural extensions is used by the Wisconsin Hydro-Electric Company at Amery, Wis. A separately formed construction company builds the lines, for which it receives payment from the central station in installment bonds having a face value of $500 each payable in twenty-five annual installments of $20 each. The annual payments cover both principal and interest.

The construction company has the privilege of selling the bonds to prospective customers on a rural-service line at $300 each. The plan is to sell a sufficient number of bonds to cover the entire expense of the extension for any given group of consumers. The $200 in addition to the purchase price covers the item of interest over the period of twenty-five years. The actual working out of the payment plan is shown in the accompanying table. Column 1 shows the bondholder's investment year by year as the installments are paid. Column 2 is the interest on the actual investment each year at 5.13 per cent. Columns 3 and 4 show the payments made yearly on principal and interest and make up the $20 yearly installment payment shown in the last column.

The contract with a prospective consumer is made contingent upon the ability of the Wisconsin Hydro-Electric Company to make similar contracts with a sufficient number of consumers to justify the extension from a revenue standpoint. The customer agrees to take service for a period of five years at rates that may now or hereafter be established as reasonable by the Wisconsin Commission. Following is the form of contract used:

CUSTOMER'S INVESTMENT IN INSTALLMENT BONDS WITH COMPUTED INTEREST RATE AND YEARLY PAYMENTS ON PRINCIPAL AND INTEREST

| Year | Customer's Investment | Return at 5.13 per Cent | Annual Installment Payment on Investment | Interest | Total Annual Payment |
|---|---|---|---|---|---|
| 1st... | $300.00 | $15.39 | $12.00 | $8.00 | $20.00 |

| | | $200.00 | $300.00 | $200.00 | $500.00 |

APPLICATION AND AGREEMENT FOR RURAL ELECTRIC SERVICE

Whereas the undersigned,.............. hereinafter called "the customer," desires to obtain electric service for use on........ farm, located on the..........side of the highway and on the..........of Section........, Township.........North, Range.......West, in...........County, Wisconsin, and

Whereas the Wisconsin Hydro-Electric Company of Amery, Wisconsin, hereinafter called "the company," is engaged in the business of generating, transmitting, and supplying electric energy to the public for general use, and is contemplating the extension of service in Barron and adjoining counties, and

Whereas the Amery Construction and Supply Company of Amery, Wisconsin, hereinafter called "the construction company," is in the business of constructing and contracting, and desires to obtain a contract from the company to construct the said proposed extensions, and the company has proposed to the construction company, to employ it to construct said extension and to pay it in installment bonds of the said company for the total sum of principal and interest of five hundred dollars each, payable in twenty-five annual installments of twenty dollars each, beginning on the first day of January, 1923, and thereafter annually, until paid, said annual installments to be in lieu of both principal and interest with the privilege of said construction company selling said bonds to prospective customers along said extension, for the sum of three hundred dollars each, and soliciting contracts similar to these presents, and

Whereas the customer subscribing hereto firmly believes that there are many others along the highway leading from the company's high-tension electric system at.... .....of Section.........., Township..... ....North, Range..........West, past the customer's farm and to................. in the County of.............., Wisconsin, who are also desirous of obtaining electric service, and who will sign a contract similar to these presents, in the aggregate to warrant the construction of such extension and to insure a reasonable return to the company on its investment, the customer therefore hereby authorizes the company to proceed with the construction of an electric extension that will supply............with single-phase, alternating-current electric service, at 115 and 230 volts, 60 cycles, delivered to and connected with the customer's nearest building on the premises above described, nearest to the company's transmission line; as soon as, in its judgment, sufficient applications and agreements similar to these presents have been obtained to warrant the construction thereof, and to insure the company a reasonable return upon its investment, it being understood that unless such sufficient agreements are obtained within one year from date hereof, then this contract shall be void; it being further understood that all cost of furnishing and constructing the transmission line along the highway and the branch line from the highway to the customer's nearest building and including transformer, lightning arresters, meters and all other equipment up to the meter, are to be paid for and thereafter to be maintained by the company so long as the customer desires service; all wiring beyond the company's physical connection to the customer's nearest building is to be provided by the customer at..................expense.

In consideration of the construction company and the company soliciting and being able to obtain a sufficient number of applications and agreements, in the company's judgment, to warrant it in constructing the electric extension applied for, and in consideration of the construction company entering into a contract with the company to construct the said extension, and to accept in payment thereof the bonds of the company above mentioned, the customer hereby agrees to take over and purchase from the construction company.... ..........of said installment bonds in the sum of principal and interest of five hundred dollars each, and to pay the construction company for the same the sum of three hundred dollars for each of said five hundred dollar bonds, one of said bonds to be accepted and paid for when the poles for said extension have been distributed out as far as the customer's premises; and an additional............of said bonds to be accepted and paid for upon the completion of said line and when it is energized for use of the customer.

In consideration of the premises, and of the company constructing the lines applied for, the customer hereby further agrees to give the company free use of right-of-way across any of his lands along the route taken for said electric line and extensions, together with permission to trim any trees, so that they will clear the wires and equipment of the company at least fifteen feet, on any property owned by............

The customer,.........successors, heirs, or assigns, further agree to take and pay the company for electric service for a period of at least five years beginning not later than sixty days from the time said lines are energized by the company at such reasonable rates and charges for rural service and energy as are now, or may hereafter be, established by the Railroad Commission of Wisconsin.

It is understood and agreed by the customer, and also by the company and the construction company, that this application and agreement, when duly signed by them, is a binding agreement, and in the event that sufficient similar agreements are obtained within one year to warrant the company, in its judgment, to make said extension, this agreement shall not be subject to cancellation or revocation.

## An Unbiased Criticism of Municipal Ownership

SELDOM is it possible to find an expression concerning municipal ownership which is not tinctured by the prejudices of one side or the other. For that reason an editorial, "The Power-Plant Issue," appearing in the Aberdeen (Wash.) *Daily World* of Feb. 15 is particularly refreshing. It deals with the taxation on the income of the municipal plants in Seattle and Tacoma for service which they propose to render by extending their lines beyond the corporate limits of those cities. In an impartial manner the editorial questions the efficiency of municipal operation and points out the unfairness of competition between the tax-exempt plant and the privately owned company. It further emphasizes the fact that after all the public pays the freight, for it must make up, through increased taxation, the loss sustained by the removal of city-owned property from the tax rolls. The editorial reads:

Seattle and Tacoma, in both of which the power plants are municipally owned, desire to sell power outside their city limits. The Legislature, so far as present proceedings go, thinks that if they are permitted to do so, they should be taxed for the privilege. The proposal is that they shall pay the state a tax on earnings. Objection is made to this on the ground that municipal enterprises ought to be tax-free, that in return for tax exemption they provide the people with cheaper power.

But there is another side. If these power plants were not municipally owned, they would be privately owned

and the private owners would pay taxes on the property. The transfer of these plants to municipal ownership simply means that that much property has been taken from the tax rolls. If the state goes on doing that sort of thing, private enterprise will be driven out, along with the taxes private enterprise pays. That is the aim in certain quarters. But even if it is achieved the state will still need revenue. It will get it in one way or another. The people will pay it. There is no other outcome. There can be no system of taxation that will make one certain class pay all the expenses of government with the majority exempt.

The question involved in this power issue is whether the municipally owned plant is entitled to a tax advantage over the private enterprise. If the private enterprise were not subject to state regulation, which it is; if its earnings were not limited by the state, as they are, and if its service were not controlled under the law, the municipal plant would be entitled, perhaps, to state aid, which is what a tax exemption amounts to. But since the state assumes power over the private enterprise and practically takes charge of it, why should the municipal plant be tax exempt? If it is to survive, it must do all the things that private enterprise is supposed to do and do them just as well. It should have no advantage.

In going outside their own domains Seattle and Tacoma ought to stand on the same basis as any other purveyor of power. Why not? Communities outside Seattle and Tacoma are not concerned with the success of the Seattle or Tacoma power plants, which were designed in the first place to serve the people of those two cities. That is their sole function. With that the people of the state have no concern. But the state is not entitled to give these cities a subsidy in the shape of tax exemption so that they can sell their surplus power outside their city limits. That is especially true when other power concerns stand ready to furnish the service the Seattle and Tacoma city plants want to furnish.

These city-owned plants enter the outside field under the advantage of no taxes at home. They ought to be able to sell power cheaper than other companies, which contribute to the support of the state, without asking a further subsidy from the public. They ought to be able to undersell the private company even with a 5 per cent earnings tax. If they cannot, and it appears they think they cannot then it must be that public control and management of business enterprise is neither so efficient nor so economical as private operation. And that is the truth. The public enterprise, with every advantage on its side, cannot compete with the private enterprise. It never has in this country, and chances are it never will. In order to maintain it at all, the people must pay. But their concern ought to be to get power as cheaply as possible and service as good as possible. Why should they subsidize municipal plants when they can get power as cheap without the subsidy? Why should they care where the power comes from so long as their needs are met at a reasonable price? And why should they dig down in their pockets to pay the taxes the municipally owned plants of Seattle and Tacoma should pay?

Tax exemption as enjoyed by municipally owned utilities is the "ace in the hole" whereby their advocates have been able to show an apparent saving over the privately owned company. How much importance municipal authorities attach to this form of special privilege is indicated by objections raised by Seattle and Tacoma to payment to the state of a tax on earnings which would accrue to them if they extend their lines beyond the city limits.

## Portable Exhibit Displays Better Window Lighting

TO EDUCATE the merchants of the state to the advantages of better window lighting and higher intensities of illumination, the California Electrical Co-operative Campaign is using the portable window-lighting exhibit shown in the accompanying illustration. The window is a model in every respect, with equipment of the latest design. It has been made large enough to accommodate a good-sized display and is provided with three types of fixtures used to give low, medium or high intensity of illumination. Daylight lamps with which it is possible to obtain an intensity of approximately 100 foot-candles are used.

PORTABLE WINDOW-LIGHTING EXHIBIT BEING SHOWN THROUGHOUT CALIFORNIA

The display is being shown by the electric clubs of the state at special merchants' day programs which the clubs have arranged. The trimming of the window is done by an experienced window trimmer supplied by some one of the merchants of the city, and the display is in charge of a special demonstrator. The chart shown at the right in the picture gives the results of the survey made in Cleveland last year to determine the relative drawing power of show windows with various kinds of displays and different intensities.

## A Bonus Plan to Increase Appliance Sales

TO CREATE and maintain interest in the sale of merchandise, the Pacific Power & Light Company, Portland, Ore., has adopted a plan of merchandising bonuses for employees which became effective the first of the year. In the past the company has achieved good results during periods of campaigns, but it was not practicable to increase the yearly volume of sales to a satisfactory amount by one or two successful campaigns a year. The company operates in eighteen districts in three states — Oregon, Washington and Idaho—and it is expected that the plan will bring about continuous selling effort throughout the year. A brief outline of the bonus plan and average sales during the past six years is interesting.

The amount of the bonus accruing to any district will be a fixed percentage of the merchandise sold in that district. To each district a yearly and quarterly sales quota is given, based on the number and classification of customers served. The bonus money will be distributed quarterly, and in order to qualify the district sales must equal or exceed the quota assigned for the period. The quarterly bonus will amount to 2 per cent of the gross sales, in addition to which 1 per cent will be paid at the end of the year on the amount by which the yearly quota has been exceeded. Provided each quarterly quota is reached, this would mean 2 per cent on the yearly quota and 3 per cent on all over that figure.

The quotas for the districts have been placed much lower than the anticipated sales in 1923, and every district is expected to be able to exceed its quota by a comfortable margin.

It is interesting to note how the quotas given the districts compare with the average yearly sales for the past six years, during which time the Northwest has experienced a variety of business conditions. The tabulation shows the relation between average yearly sales for six years and the quota assigned for 1923.

AVERAGE YEARLY APPLIANCE SALES DURING LAST SIX YEARS

| District | Per Cent of 1923 Quota | District | Per Cent of 1923 Quota |
|---|---|---|---|
| Astoria | 113 | Prosser | 224 |
| Dayton-Waitsburg | 105 | Seaside | 97 |
| Goldendale | 183 | Sunnyside | 86 |
| Hood River | 91 | The Dalles | 88 |
| Kennewick | 182 | Toppenish | 105 |
| Pasco | 100 | Walla Walla | 80 |
| Lewiston | 130 | White Salmon | 157 |
| Pendleton | 90 | Yakima | 107 |
| Pomeroy | 165 | Vancouver | 120 |

It will be seen that in twelve of the eighteen districts the average yearly sales equaled or greatly exceeded the quota established for 1923. No district failed to sell less than 80 per cent of the 1923 bogey. Taking each year's sales separately, it is found that in 1917 thirteen districts exceeded their quota, in 1918 eleven districts exceeded their quota and in 1919 every district went over the mark set. In 1920 all but two districts sold more than the quota allotted to them, and in 1921, the poorest year experienced in the sale of merchandise, six districts exceeded their quota, while in 1922 the number was increased to ten.

## Observance of Safety Rules Rewarded by Extra Vacation

EMPLOYEES of the Dallas (Tex.) Power & Light Company engaged in hazardous work who go the entire year without personal injury will be allowed extended time on their vacations as a reward. The announcement of this policy was made by C. E. Gill, vice-president and assistant general manager, at the annual safety meeting of the employees. C. E. Calder, president of the company, addressed the men and paid high tribute to the work of the engineering, construction, organization, distribution and operating departments, which, by adoption of safety methods, have materially reduced the number of accidents and time lost on this account. As an additional incentive to observe safety rules, the sixteen crews in the distribution department will compete in a contest for the best record in the application of safety rules and practices, and suitable rewards will be given members of the winning team.

## "Quality" Merchandising by the Central Station

RELIANCE of the public upon the word of the central-station company has long been a potent factor in the growth of appliance sales. That the great majority of central stations are rendering a good account of their stewardship is reason for congratulation within the industry. The accompanying rather unusual advertisement throws a light upon the pursuit of quality merchandise by one of the Tenney companies in Massachusetts and shows the value of testing appliances before putting them upon the sales floor.

**Here's a strange advertisement**

*It tells about an article we'll never sell you*

A manufacturer of household appliances was very anxious to have us sell his electric iron.
We submitted his iron to tests in our laboratory. It was satisfactory in many respects. But—we quote the laboratory report—
"The nickel plating is insufficient to prevent the surface from rusting."
So that's why we'll never offer that iron for sale. You can't buy it from us.
Our business depends on your satisfaction. We take care to offer only such articles as give true value and efficient service.

**Suburban Gas & Electric Company**

C. F. Chisholm, Mgr.

**Telephone Revere 145 or Ocean 254**

## What Other Companies Are Doing

**Hartford, Conn.** — The appliance department of the Hartford Electric Light Company in 1922 had a very successful year, passing its bogey of 10,000 sales by 247. Following are the numbers of the principal appliances sold: 4,034 flat irons, 1,124 cleaners, 1,061 portable lamps, 834 radiators, 589 toasters, 271 percolators, 244 washers, 299 heating pads, 44 electric ranges.

**Springfield, Ill.**—The Central Illinois Public Service Company sold 18,763 shares of its preferred stock in its own territory during the year 1922. This is 300 per cent greater than the sales for any previous year. The company's stockholders increased in number from 2,355 to 4,541. In addition, there were at the end of the year, on account of these and other sales, 5,643 subscribers for stock on the partial payment plan. A total of 993 employees sold one or more shares each during 1922. The company had at the close of the year stockholders and subscribers for stock in the ratio of one for less than nine electric customers served.

**Malden, Mass.** — In a recent house-wiring campaign under the auspices of the Malden Electric Company the owner of fifty-four dwellings authorized the minimum installation of three floor outlets per home, which formed the basis of the development of business under central-station and contractor-dealer auspices. Tenants were left free to expand the initial installation and in many parts of the company's territory the three-outlet initial installation was regarded as only a starting point by the local public.

**Texas.** — The Texas Power & Light Company recently completed the reconstruction of its offices at Denison, Taylor and Sweetwater to provide the best possible accommodations for customers both for routine transactions and for the merchandising of appliances. In the case of the Denison office the company arranged to move from a side street to a site in the center of the business section. The office chosen was completely renovated and arranged for the attractive display of electrical merchandise. G. B. Richardson, the company's merchandise sales manager, argues that every customer who comes in to pay a bill is a possible purchaser of energy consuming appliances and that facilities should be provided for their careful inspection.

**Astoria, Ore.**—At the recent meetings of the Commercial Section of the N. E. L. A. at Denver John V. Strange of the Pacific Power & Light Company of Portland, Ore., brought out an interesting condition with regard to electric bake ovens as a result of the fire which recently destroyed the business section of Astoria. The company supplies both gas and electric service in the city, and, desiring to retain as much gas business as possible in the reconstruction after the fire, gas rates for industrial uses were reduced to below pre-war rates. In spite of this fact every commercial bake oven which will be installed will be an electric oven.

# Digest of Electrical Literature

Including Brief Abstracts of and References to Important Articles Appearing in the Scientific and Engineering Press from All Parts of the World

## Hydro-Electric Development and Steam Equipment

*Design of Structural Supports for Turbo-Generators.*—The relative merits of the three common types of foundations or pedestals for steam-turbine units—that is, reinforced concrete, structural steel and composite construction, are discussed in this paper, which was presented by E. H. Cameron before the American Society of Civil Engineers on Dec. 20. The restraint of vibration, provision for repair of auxiliaries and restrictions of deflections should be the controlling factors of the design. The author suggests that the basis of comparison in deciding on a type of pedestal for a turbo-generator installation should be solely utility or fitness, rather than relative cost.—*Power*, Jan. 23, 1923.

*Water Developments on the St. Lawrence River.* — NEWTON FUESSLE. — A general discussion of the hydro-electric development that is being considered on the St. Lawrence River. Virtually 5,400,000 hp. is available and if totally developed it would save 54,000,000 tons of coal each year. The article was written following an interview with Hugh L. Cooper on the subject.—*Outlook*, Jan. 31, 1923.

*Modern Jet Condensers in Small Lighting Plants.*—R. E. HELLMER.—Condensing equipment is essential to the economical operation of a steam-power plant. There are two classes of condensers, namely, surface and jet types. The question as to which is the better type to employ in a particular power plant should be determined wholly by the operating conditions that exist at the plant. The author describes a variety of installations using the jet type of condenser, particularly small power plants.—*General Electric Review*, January, 1923.

## Generation, Control and Switching

*Voltage Maintenance on Direct-Current Systems.*—P. J. ROBINSON.—The problem of maintaining a constant voltage over a network and keeping down costs has resulted in the installation at Liverpool of an automatic substation. The equipment of the station includes one 500-kw. rotary converter, coupled through a transformer to a 6,000-volt, three-phase, 50-cycle supply on one side and to a three-wire, 460-volt direct-current circuit on the other. An electrically operated oil switch with an alternating-current closing coil is used to control the rotary converter. Other apparatus includes a three-phase transformer for the various instruments, isolating switches, a low-tension direct-current panel for the rotary converter, low-tension feeder panels for control of the four three-wire feeders, etc.—*Paper presented before the Institution of (British) Electrical Engineers*, Feb. 1, 1923.

*Remote Supervisory Control.*—J. L. McCOY. — The author describes a method by which there are transmitted a series of low-frequency impulses which are interpreted by electromechanical apparatus at the receiving end of a system, thus enabling a load dispatcher at all times to control the system. When initiated these impulses cause the actual operation at remote points. The receiving apparatus in such cases translate the series of impulses directly into an operating impulse, performing the desired switching operation.—*Electric Journal*, February, 1923.

## Transmission, Substations and Distribution

*Transformer Designed to Conserve the Oil and Eliminate Explosions.*—W. M. DANN.—On account of the number of explosions of serious nature in power transformers a new type of transformer has been designed for the prevention of disasters. The author first considers the conditions producing explosions and then describes the transformer, in which inert gas such as nitrogen is employed over the oil or in an expansion tank. A compartment containing a deoxidizing material is mounted on the wall of the tank and is connected to the nitrogen space by means of pipes. Within this compartment is a valve which by means of a mercury seal isolates the nitrogen body from the atmosphere within certain predetermined limits. A dehydrator is placed in the connections between the deoxidizing compartment and the gas space to remove all traces of moisture from the ingoing gas.—*Electric Journal*, February, 1923.

*Predetermination of the Heating of Self-Cooled Transformers.* — R. KÜCHLER.—The author develops formulas for the calculation of the heating of tanks, cores and windings of core-type, oil-immersed, self-cooled transformers. Tested on fourteen standard transformers of well-known make, the different formulas come in 60 per cent of the cases within about one degree of the observed value. In the remaining cases considerable discrepancies occur, but the author ascribes these to measuring inaccuracies. — *Elektrotechnische Zeitschrift*, Jan. 18, 1923.

*The Lead-Cable Borer in California.*—H. E. BURKE, R. D. HARTMAN and T. E. SNYDER.—Experiments indicate that the cable-borer beetle is able to penetrate any lead alloy used as a cable sheathing or any poison or repellent placed on the sheathing. The greatest damage done by these beetles is to the lead sheathing of telephone cables in California. The extensive report gives a review of the injury done throughout the world to metals by boring insects, damage by the California lead-cable borer to trees and forest products, a history of the beetle and an account of the investigations.—*Bulletin No.* 1107 *of the United States Department of Agriculture.*

## Units, Measurements and Instruments

*Spectro-Photo-Electrical Sensitivity of Some Halide Salts of Thallium, Lead and Silver.*—W. W. COBLENTZ and J. F. ECKFORD.—This paper narrates the results of a study of the effect of crystal structure, chemical constitution and atomic weight upon spectro-photo-electrical sensitivity. It was found that the photo-electrical reaction on the above salts is confined to a very narrow region of the violet end of the spectra, being the narrowest and most sharply defined electrical spectrum of all substances yet investigated.—*Scientific Paper No.* 456 *of the Bureau of Standards.*

*Apparatus for Calibrating Alternating-Current Meters.*—W. SKIRL.—In calibrating alternating-current meters it is customary to provide a separate current and voltage circuit. Aside from a decided saving in current, this method permits an easy and independent regulation of current, voltage and phase displacement. Special transformers are described to regulate current and voltage in a great number of fine steps from zero up to the full meter rating. Motor-generator sets with one rigid and one adjustable stator are described which serve to obtain any desired phase displacement. The author describes some actually built single and three-phase testing switchboards and gives their complete wiring diagrams.—*Siemens Zeitschrift*, December, 1922.

## Motors and Control

*Direct Current.*—O. POLLOK.—The author shows that while for high-tension transmission three-phase alternating currents are beyond dispute the best system, transformation into direct current for motor drives has many and valuable advantages over the use of three-phase motors. The necessary small air gap of induction motors, the lack of speed regulation, the very poor power factor at low or no load, their straight motor character without the possibility of generative braking, the 50 per cent larger number of starter contacts and connections, are all decided disadvantages as compared with the direct-current motor. The latter has been much improved with the introduction of commutating poles, and the usual troubles with the commutator do not exist with well-made, modern direct-current motors. For the drive of tool machines, if three-phase motors are

used, a large number of gears, gear cases, friction clutches, fly wheels, etc., are usually required, in order to obtain the necessary number of speeds. As an example, a milling-machine drive is shown with twenty-four gears, six shafts, two clutches and four operating levers, which give sixteen different speeds from 5.5 r.p.m. to 200 r.p.m. of the spindle. A similar drive, equipped with a variable-speed direct-current motor, contains only nine gears, two shafts and two levers and gives 120 speeds between 5.5 r.p.m. and 200 r.p.m. of the spindle. The drive of a 3-ton crane is mentioned where a 22½-hp. direct-current motor gave the same hourly lifting output as a 45-hp. three-phase motor, the latter consuming 40 per cent more watt-hours. A saving in current of from 35 per cent to 40 per cent can be realized by driving feeding rolls on blooming mills with direct-current motors instead of induction motors, aside from the much simpler controlling apparatus for direct-current motors. It is emphasized that the safety of a drive depends not only upon the reliability of the motor itself, but also upon that of the necessary control apparatus, which is much greater for a two-wire direct-current system.—*Elektrotechnische Zeitschrift*, Jan. 11, 1923.

## Illumination

*Adequate Street Lighting a Municipal Necessity.*—F. M. REAST.—Effective lighting for streets and highways is of the utmost importance to every town and city. Based on a recent report of 3,223 fatalities which occurred during the hours of darkness in a large number of cities in the United States, it was found that 15.6 per cent were directly attributed to lack of sufficient illumination. This indicates very pointedly the conditions that must exist in localities where effective lighting facilities are not available.—*Central Station*, February, 1923.

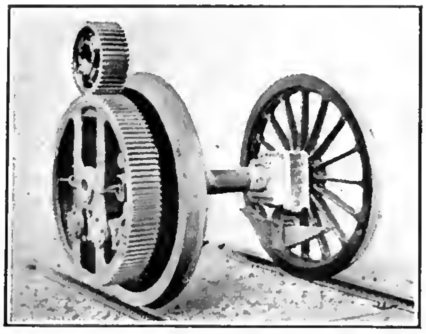
## Electrophysics, Electrochemistry and Batteries

*Preparation and Properties of Pure Iron Alloys.*—W. L. CHENEY.—The author discusses the results of a study of the effect of heat treatment and chemical composition on the magnetic properties of a series of unusually pure iron-carbon alloys ranging from pure iron to 1.6 per cent carbon. Magnetization curves and hysteresis data were taken after each heat treatment and microscopical analysis were made after certain selected heat treatments. The hardened alloys when drawn back to successively higher temperatures showed marked changes in the normal induction, residual induction and coercive force which correspond to transformations of the material. They also showed variations in the maximum intensity of magnetization as computed from the reluctivity relationship. Microscopic analyses confirmed in the majority of cases the fact that the number of values of intensity indicates the number of constitutents present in the material. Variations in the maximum permeability for some alloys show greater differences than other magnetic quantities. Comparing the magnetic properties with the carbon content, there were found certain changes in these properties as the carbon content was increased.—*Scientific Paper No. 463 of the Bureau of Standards.*

*One-Axle Electric Mule.*—D. TRAUTWETTER.—A newly developed electric mule is described which has only one axle, to each end of which is fastened a solid rubber-tired double wheel of about 18-in. diameter. A 3½-hp., 60-volt motor is mounted above the axle and actuates by means of a chain a differential worm drive. On each side of the axle is suspended one half of the 36-kw.-hr. storage battery, which, under normal service conditions, is charged every two days. The mule has a pull of 250 kg. on the wheel circumference, weighs 1,500 kg. and develops a speed of 1 m. per second. The operator walks in front of the vehicle.—*Elektrische Betrieb* (formerly "*Elektrische Kraftbetriebe und Bahnen*"), Jan. 10, 1923.

## Traction

*Individual Axle Drive for Locomotives.*—In the new drive described the motor is between the wheels of the driven shaft and connected to it over a single reduction gear, the large wheel of which is outside of the axle journals. The pinion on the motor is not keyed solidly to the shaft, but contains four intermediate springs. The large gear wheel is connected to the driven axle by a somewhat complicated lever mech-



SET OF LOCOMOBILE DRIVING WHEELS WITH OUTSIDE GEARING

anism, which permits a considerable misalignment between the centers of the gear and the wheel in every direction. Sixteen distinct advantages of this drive are enumerated, and locomotives of the same power output, one with the conventional rod drive, the other with the new drive, are compared. The first locomotive built with this individual axle drive has recently been inspected after running 66,000 miles, and no traces of wear have been noticed, nor was it necessary to make any readjustments.—*Brown-Boveri Mitteilungen*, January, 1923.

*An Analysis of Regenerative Braking on Electric Locomotives.*—C. E. FAIRBURN and F. A. HARPER.—As a result of extended investigations, characteristic curves of locomotives regenerating energy used for braking have been made for the authors. Motor characteristic curves which show the horsepower, tractive effort, speed and efficency plotted against the current input are well known, and the problem of regenerative braking is handled in a similar manner. The mathematical solution of the curves developed is given.—*English Electric Journal*, Vol. II, No. 2.

*New York, London, Paris and Berlin Transit Compared.*—D. L. TURNER.—In the matter of transportation methods a somewhat different condition prevails in this country from that in Europe. Attention is directed to some of these points of difference in a report presented before the New York Transit Commission by the author, who spent some time in Europe studying city transit conditions. One striking point brought out is the far more strict adherence to rules on the part of European crowds. Another point of difference is the better methods used by European railways to give travelers the information they want. This is done in a variety of ways—by signs on the cars, maps in poster form, direction signposts and other methods which make traveling by street car abroad easy for the stranger.—*Electric Railway Journal*, Jan. 13 and Jan. 27, 1923.

## Telegraphy, Telephony, Radio and Signals

*Standardization of Wavemeters.*—A. TSUBOUCHI.—The establishment of an accurate standard wavemeter is based on calculating the inductance and measuring the capacity of a standard wavemeter and computing the wave lengths from these quantities combined. For checking or correcting the wave lengths harmonics drawn from a triode generator are made use of. Thus the range of wave lengths from about 200 m. to about 22,000 m. are covered by the standard wavemeter. In order to cover a wide range of wave lengths a series of eight standard coils of simple forms with larger inductance than that of the square coil has been made. Combining these series of coils and the standard condensers, the required range of the standard wavemeter has been covered.—*Research No. 115 of the Electrotechnical Laboratory*, Tokyo, Japan.

*Permissible Telephones for Coal Mines.*—The Bureau of Mines is prepared at its Pittsburgh experiment station to conduct inspections and tests of telephones designed for use in coal mines. A telephone submitted for permissibility tests is to be so designed and constructed that under no circumstances can its normal operation cause ignition of either dust or gas, or a combination of dust and gas, in the surrounding mine atmospheres. A thorough inspection of the telephone will be made to determine its adequacy and permissibility. Tests will be made to check the electrical characteristics and constants of the various parts, and to determine the adequacy of the insulation and of other parts or features of the apparatus.—*Schedule 9-A of the Bureau of Mines.*

## Electrical Engineering Laboratory Experiments

By C. W. Ricker and Carlton E. Tucker. New York: McGraw-Hill Book Company. 310 pages, illustrated.

This book is a commendable compilation of the usual laboratory experiments for engineering students. With each experiment is sufficient explanation to guide the student who has not thoroughly studied the theory connected therewith. At the end of each experiment a list of the results required is given, subdivided into several parts. This permits an instructor utilizing the book as a laboratory manual to assign certain parts for a given laboratory period or for a given group of students. Other parts may be entirely omitted or assigned at some other time. Thus the book is adapted to the use of many different types of classes and also indicates to the student the portion of the standard tests which he is not required to perform, leaving no doubt in his mind that he has not mastered the complete field. The list of additional references is very desirable for the student who wishes more information on the subject at hand.

Naturally the laboratory manual must be based on the apparatus available to the student for the performance of the experiment. Although the experiments are of a quite general nature, it is obvious that the writer has in mind perfectly definite apparatus. This is as it should be, and any institution utilizing a book of this nature should keep this fact in mind, making such modifications as may be necessary.

Many institutions prefer the loose-leaf manual of instructions containing little or no theory. Such sheets can be filed with and as a part of the complete report. The advantage of the bound manual is its availability for reference.

R. G. Warner

## The Twelve-Hour Shift in Industry

By the Committee on Work Periods in Continuous Industry of the Federated American Engineering Societies. New York: E. P. Dutton & Company. 302 pages.

The title of this book is a misnomer. It treats chiefly of eight-hour shifts and gives no economic or engineering reasons for changing from the longer to the shorter work period. Such reasons as are vouchsafed are sentimental and humanitarian, and these appear unwieldy instruments in the hands of engineers. Where good management and co-operation of labor prevail a shorter day has proved advantageous; but how much credit is due to management, good relationships, labor-saving devices, etc., and how much to the shorter period of labor, is hard to determine. From 5 to 10 per cent of industrial work is on processes requiring continuous operation, and of the men engaged in such work only one-half to one-third operate on twelve-hour shifts, so that the argument is directed to only a small part of industry. That part comprises the iron and steel works, and there the plea is hardly necessary, because those in authority are already convinced of the necessity of a change to a shorter work period. Judge Gary of the United States Steel Corporation has addressed the presidents of the subsidiary companies on this point as follows: "I am not going to argue in favor of the twelve-hour day. I am opposed to it if and when it can be eliminated, not because I think it is necessarily harmful but largely for the reason that there is more or less public sentiment against it." Public opinion will be more potent in effecting a change than any engineering study, and the present volume can add little in the way of argument and proof to minds already made up upon the desirability of an eight-hour day.

## Rate Making for Public Utilities

By Lamar Lyndon. New York: McGraw-Hill Book Company. 209 pages.

This book is fundamentally a thesis on the question of valuation and rate making for public utilities in which the author expounds and explains—in fact, argues—his analysis of the proper approach to these problems. It cannot be gainsaid that the whole thesis is fair. Of all the various bases of valuation, that which will clearly support the integrity of the honest investment is held to be the most sound on economic, social and ethical grounds. In the treatment of his subject the author indulges in few generalities, but confines his statements and arguments to the various phases and elements of valuation and rate making. There is never any doubt as to what is being talked about or said. In his foreword the author says the book "is not partisan in any respect," but that "at first glance it might appear that this book is antagonistic to the public service corporations." It is not hard, though, to agree with him that "such, however, is not the case," if the public service corporation's real interests are considered.

The author does not hesitate to criticise, and try to educate, both public utility engineers and engineers for the public. He takes a justified fling at engineering experts who "claim that they can tell by inspection how far a plant has depreciated. They can look it over and say, at once and without hesitancy, just what condition it is in, just how much of its life has expired and what its remaining value is, and these statements they can make so surely and definitely that they testify under oath, in court, that these statements are facts and truly so."

There are closing chapters on rate making for gas supply, for electrical supply, for electric railways and for telephone service, in which the individual characteristics of each utility service are carefully analyzed. This is a book which any one who has anything to do with public utility economics, operation, control or criticism should not fail to read. It should do much to prevent divergence between engineers for the public and engineers for the public utility.

H. V. Bozell.

## Freileitungsbau Ortsnetzbau

By F. Kapper. Third edition. 368 pages, 364 illustrations, 2 plates and 53 tabulations. Munich and Berlin: R. Oldenbourg.

The fact that this book has had three editions within seven years well bespeaks its popularity. The author covers the vast subject of dimensioning and installing of main and distribution lines in a comprehensive and simple manner, interspersing constantly actual examples of existing lines and network. A great many valuable working drawings are included in the text, such, for example, as steel-tower constructions for long-distance spans. The use of survey instruments and methods for the quickest lay-out of the right-of-way of lines are among the subjects treated in the twenty-seven chapters. A useful book for the construction engineer in the field.

A. Palme.

## New Electric Power Handbook

Cleveland: The Electric Power Club. Fourteenth edition. 364 pages.

This volume, which is given without charge to consulting engineers, architects, electric light and power companies, educators and rated electrical contractors and dealers, covers substantially all the standardization the club has effected in electric motors, motor pulleys, generators, transformers, electric tools, mining and industrial locomotives, control equipment, power switchboards and switching equipment manufactured in this country. The handbook also contains definitions, symbols, general engineering recommendations and other information needed by users and purchasers of electric power apparatus and control equipment.

## Merger of Illinois Utilities

**Illinois Power & Light Corporation Organized to Take Over McKinley and Studebaker Properties**

SENATOR McKINLEY and others associated with him are proposing a consolidation of the southern Illinois properties controlled by Clement Studebaker and his associates with the properties of the Illinois Traction Company.

The plan provides for the retirement or exchange of approximately $50,000,000 of securities and the creation of a new company, all of whose common stock will be owned by the Illinois Traction Company.

All of the operating properties of the Illinois Traction Company in Illinois will be consolidated into one company, to be known as the Illinois Power & Light Corporation, which will acquire through consolidation the properties operated by the Southern Illinois Light & Power Company. To accomplish this consolidation and to establish a proper foundation for a new first and refunding mortgage for the consolidated operating company, including the creation of an attractive preferred stock, it is planned to acquire approximately $22,000,000, par value, of bonds and to call for redemption a further $9,000,000 of bonds now in the hands of the public. It is also proposed to acquire approximately $9,300,000 of guaranteed preferred stock issued by subsidiary companies and $1,641,000 of preferred stock of the Illinois Traction Company. All these holdings will either be canceled or pledged under the new mortgage. In addition it will be necessary to provide for the retirement of $5,649,000 of Illinois Traction preferred stock, $2,169,000 of Western Railways & Light preferred, $1,665,000 of Southern Illinois Light & Power preferred and $631,000 of Bloomington & Normal Railway & Light preferred, all of which are now in the hands of the public. The intention is to offer the holders of these securities in exchange therefor a like amount of 7 per cent cumulative preferred stock of the new Illinois Power & Light Corporation.

CAPITALIZATION OF ILLINOIS POWER & LIGHT CORPORATION

| | |
|---|---|
| Divisional bonds (including Southern Illinois Light & Power bonds) | $36,414,800 |
| First and refunding mortgage 6 per cent bonds | 30,000,000 |
| Thirty-year 7 per cent sinking-fund debentures | 10,000,000 |
| First preferred 7 per cent cumulative stock, par $100 | 17,678,500 |
| Participating preferred stock, 6 per cent cumulative, par $50 | 1,865,500 |
| Common stock, no par value | 400,000 shares |

For legal reasons it will probably be necessary for the Illinois Power & Light Corporation to control through stock ownership the Illinois interurban railways and the utilities operating in states other than Illinois.

The capitalization of the new company, subject to the approval of the Illinois Commerce Commission, is given in the accompanying table.

## Alabama Power Company to Reduce Retail Power Rates

Reduction of the cost of electric power furnished under retail power contracts by the Alabama Power Company and the Sheffield Power Company is provided for in a formal order issued by the Alabama Public Service Commission last week following an agreement with the companies. The rate follows: Demand charge, $1.50 per month per kilowatt, plus energy charge, 3 cents per kilowatt-hour for the first 1,000 kw.-hr. consumed per month, plus 2 cents for the next 4,000 kw.-hr., plus 1 cent for the next 15,000 kw.-hr., plus 0.9 cent for the next 30,000 kw.-hr. It is specified that the demand shall be determined by either inspection or demand meter, but in no case shall it be less than 1 kw.

## Committee on Insulation Is at Work

During the midwinter convention of the American Institute of Electrical Engineers held at New York last month there was a meeting of members of the committee on insulation of the National Research Council. This committee numbers about forty men, but it is to a small active group among this large membership that the Engineering Division of the National Research Council looks for the pushing of the work. Those present at the meeting were J. B. Whitehead, chairman of the committee; G. B. Shanklin, F. M. Farmer, W. A. Del Mar, R. W. Atkinson and A. D. Flinn, chairman of the Engineering Division. Their preliminary report, as prepared by the chairman, will be a general statement of the important problems in the field of insulation attacked from the simplest fundamental aspects with specific suggestions of problems for experimental approach. The more complex questions continually propounded by the industries will be left for a later date.

## Ford Gets High Dam

**Preliminary Permit Granted as Concession to Sentiment in Twin Cities —Rigorous Conditions**

WHAT is very apparently a concession to public opinion in the locality affected was made by the Federal Power Commission in awarding a preliminary permit to Henry Ford covering the High Dam project in the Mississippi between Minneapolis and St. Paul. To guard against non-use such as has followed the construction of the Ford dam at Troy, N. Y., and to safeguard the public interest in other ways, the commission imposed very strict conditions.

In the first place, provision is made to insure the maximum possible utilization of the power. Mr. Ford is required to install four units with the maximum capacity of 4,800 hp. This is all the power that can be developed without extensive and expensive changes in the dam. A further condition imposed by the commission is an annual charge of $95,500 for the use of the government's dam. Mr. Ford is also required to put in a tailrace 2,000 ft. long, so as to prevent the silting up of the navigation channel and the lock. The commission feels that these rather rigorous conditions are necessary in order to insure the use of the power in the public interest.

NORTHERN STATES MAY BUY POWER

Mr. Ford is required by the permit to apply for license before July 1. On that date he must present executed contracts for the sale, delivery and use of the maximum power that can be delivered at the dam. This probably means that a large block of the power must be sold to the Northern States Power Company. That company is understood to be ready to purchase such power as Mr. Ford has to sell, but since it is now securing dump power for 2½ mills per kilowatt-hour, delivered, it was brought out clearly at the hearing that the company would not be willing to pay a higher rate to Mr. Ford. It could be discerned that the Northern States Power Company has some apprehension as to what might develop if one or both of the municipalities adjacent to the High Dam should receive power for general use.

Doubtless with some of the extravagances of another Ford development in mind, the commission required as a condition of the preliminary permit that the development be made along the most efficient and economical lines.

Chief Engineer Mayo of the Ford

staff, who appeared in his behalf, told the commission that it is the expectation to use the power principally in electric furnaces. No attempt was made to explain why Mr. Ford is desirous of resorting to hydro-electric power for his St. Paul plant when engineers' estimates are that it will cost three times more than the power he could develop from coal at such a plant.

The president of the University of Minnesota and Representative Newton of that state made vigorous pleas for the reservation of power for the university's use and of a turbo-generator site to permit the university to carry on extensive experiments of a hydro-electric character. This plea was not granted. Under the law the commission has no right to place charges on a licensee in addition to those prescribed in the act.

# Governor Smith's Views on Water Power

### Favors State Ownership, Development and Limitation—To Continue Fight Against Federal Control—Wants Private Lines Made Common Carriers

GOVERNOR SMITH'S long-awaited message on water power was sent to the New York State Legislature last Tuesday. A remarkable feature of the message is that the issue of cost receives scant consideration. The Governor asks for an "adequate appropriation" to begin the work, but the vital question of when and how $150,000,000 is to be raised is not answered. Another outstanding feature of the message is the Governor's proposal that existing private transmission lines be made common carriers and regulated as such by the state. He opposes exportation of any power beyond the boundaries of the state.

#### THE GOVERNOR'S RECOMMENDATIONS

Declaring that the state should at once develop the power resources on the Niagara and St. Lawrence Rivers for transmission to every municipality in the state over lines owned and controlled by it, the Governor makes, in brief, the recommendations which follow:

First—That appropriate legislation be enacted to carry out this policy. "To do this will require an adequate appropriation of public funds made immediately available."

Second—That the State Engineer be charged with the duty of beginning development work and negotiating with the federal government for consent to develop hydro-electric power on these streams consistent with its control over these waters for navigation.

Third—That, pending the development of all these powers, existing transmission lines should be declared common carriers by law and compelled to transmit electrical energy at a reasonable rate.

Fourth—That no further permits or licenses for the development of power should be granted to any private corporation, existing statutes providing for such grants to be repealed.

Fifth—That $75,000 be made immediately available to the Attorney-General to enable him to defray the expenses of the action now pending and begun by the state against the federal government to determine the jurisdiction of the state over the navigable waters within its borders for power development.

On the last recommendation the Governor says:

"This action should be prosecuted with the utmost care, vigor and dispatch in order that this vital question be finally determined. We have already delayed too long. While we have been debating and bickering over the enactment of laws for the progressive development of our great water power under state ownership and control, the federal government has enacted a water-power law which challenges our right, authority and jurisdiction over the navigable waters of our state in all matters relating to power development.

"The federal government contends that it has the right, authority and jurisdiction to control and dictate by license how, when and where developments are to be made on the Niagara and St. Lawrence Rivers, as well as all other navigable streams of the state. Such right and authority, if sustained, would enable the federal government to deprive the State of New York and its people of this priceless heritage bestowed upon us by the Creator himself. In the final analysis it would permit the federal government to divert the energy created by the fall of water in our streams to other states against our will. The bed of our streams over which power-creating water flows belongs to the state, or, better still, to its citizens. Our use and control of the same is threatened. I am credibly advised that a strong and determined propaganda is now being spread in support of a plan to divert the electrical energy from our border streams to territory outside the state. This we must resist with all the power that we can bring to our command.

"No pending public question is of more moment to the people of this state than the development of this great resource. It has been exploited in the past in the interest of private corporations that have operated it for private gain. What remains of it must be developed in accordance with the enlightened thought of today, and that, I take it, is by the state itself, under state ownership and state control, to the end that all of the people may be able to realize the individual benefit which should flow to them from their own resources and their own property."

After an investigation now in progress with respect to the development of power from the surplus canal waters at Crescent and Vischer Ferry, the Governor will prepare a message on that subject.

Immediate action by the state for the development of hydro-electric power and its sale to municipalities for distribution to private consumers was urged by the New York State Mayors' Conference at its mid-winter session in Albany on Wednesday.

#### UTILITY BILL FOR NEW YORK CITY

Public utilities in New York City other than transit lines will be regulated by a single-headed department of public utilities if a bill introduced on Tuesday by the Democratic leaders shall become law.

The New York City Public Utilities Commission would be an appointee of the Mayor, but, like the New York City transportation bill, this measure provides that the Board of Estimate shall have the power to increase the number of public utilities commissioners exercising supervision for the city.

The bill gives to the city the power to own and operate gas and electric light plants and other utilities. The Board of Estimate could initiate steps for their construction or acquisition when it deemed such action advisable. As in the transportation act, the board appears to be the sole judge of the timeliness and need of such steps.

All the powers now exercised by the Public Service Commission in regard to public utilities within New York City are transferred to the prospective New York City Department of Public Utilities, which would control rates as well as the operations of such corporations.

# Surveys in Two States

### Pennsylvania and Massachusetts Contemplate Further Development of Hydro Resources

GOVERNOR PINCHOT of Pennsylvania has requested that the Legislature provide a special appropriation of $35,000 to carry on an outline survey of water and fuel resources available for Pennsylvania and of the most practicable means for their utilization for power development.

The Governor explained that the purpose is to conduct a careful study of power development possibilities both within and outside the state, expressing it as his opinion that the development of Niagara Falls, the Delaware, Susquehanna and Potomac Rivers and other sources of power is of as great interest and value to the state as if these sources were entirely within Pennsylvania.

"Such a survey should point out the way to secure for all industries, farms, homes and railroads in all parts of the commonwealth an abundant supply of cheap electrical energy while duly safeguarding existing investments in the electric industry," the Governor said.

A conference was held at Boston on

Monday at the instance of the Associated Industries of Massachusetts on the question of whether steps should be taken to ascertain the possibilities of securing additional power from Massachusetts water sources. The question at issue was whether the manufacturers would care to make a united survey of the situation, which would involve an expense probably of $50,000. President Charles R. Gow of the Associated Industries and President Charles L. Edgar of the Boston Edison company were the principal speakers.

There is a great deal of water power wasting in the state, they declared, which might be transformed into electrical energy, especially since it is impossible to bring electricity from Maine or Canada.

# Water Power National, Not Local

## Guy E. Tripp, in an Argument for a Superpower System in North Atlantic States, Protests Against Narrow View of New York's Resources

INSTANCING the interconnected system of the Southeastern States, which stretches for more than six hundred miles and embraces Alabama, Georgia, Tennessee and the Carolinas, and the still longer Pacific Coast interconnections as examples of hydro-electric practice that should be emulated in the Northeast, Guy E. Tripp, chairman of the board of the Westinghouse Electric & Manufacturing Company, has just given to the press a protest against narrow state views on the development of the water powers of New York and against basing plans on the engineering practice of 1907 rather than that of 1923.

"Large water powers," Mr. Tripp says, "are no longer merely a local asset. No matter where they are situated, they are, beyond the shadow of a doubt, a resource of the entire nation. It is now economically wrong to restrict the energy derived from them within any arbitrarily chosen limits. This energy must be so distributed that it will benefit the greatest possible number of people.

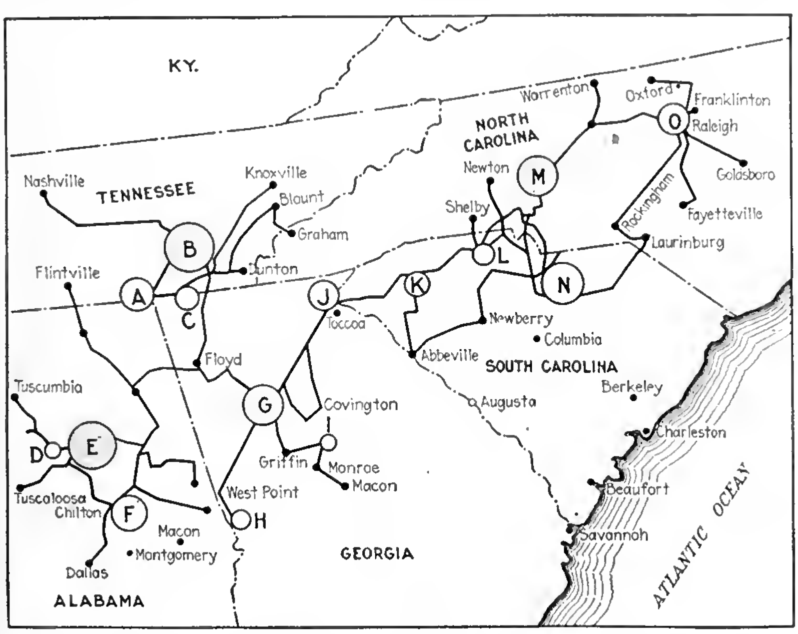
"Water power," he continues, "must be developed on a national, and not on a local, basis. From now on every hydraulic generating station should be designed with reference to a great interstate system of distribution. Engineering science has prepared the way for such a system. It has studied every source of power and every center of power distribution in America, and since it knows or can accurately estimate practically every factor involved, it has devised means for supplying all of the power needed for fifty years to come.

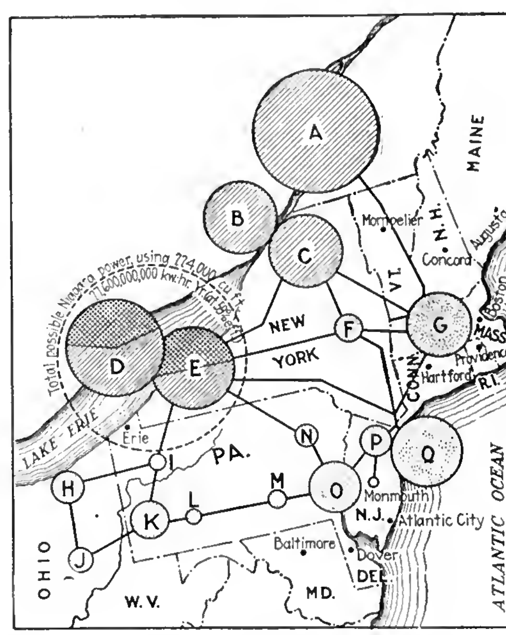
### NEW YORK MUST CHANGE POLICY

What is the situation in New York State? Though it has the finest steam and water-power stations in the world, there is no comprehensive co-operation between them. The great Niagara companies distribute power to only a narrow strip lying along the northern border of the state, and the splendid steam plants of New York City serve only the metropolitan section. As things now stand, millions of horsepower are being allowed to run to waste, vast and unnecessary sums are being spent for coal, large areas of the state are unsupplied with electricity, there is danger of power shortages because of lack of coal and other causes in even our largest city, and all through the district, relatively small generating equipments are being installed, only to be replaced by somewhat larger ones, which in turn are soon replaced, causing a continuously pyramiding of capital charges which are borne by the public. Yet, under the encouragement of the state government, together with the co-operation of the various power companies, which will undoubtedly be given, an interconnected power system, unsurpassable anywhere in the world, could be readily formed in this section."

According to Mr. Tripp, the total amount of power generated by the electric systems of New England, New York, New Jersey and Pennsylvania in 1921 was 14,000,000,000 kw.-hr.; the total power of the Niagara Falls and River is 27,000,000,000 kw.-hr. per year, and the total power of the St. Lawrence River is 21,000,000,000 kw.-hr. per year.

Mr. Tripp explains his conception of how New York's water powers should be developed by the use of two maps, here reproduced, one showing the Southern system and the other the suggested North Atlantic system, as explained in the captions. "The plans are complete," he says, "but a leader is needed to put them into execution."





SOUTHERN SUPERPOWER SYSTEM, AND PROPOSED SUPERPOWER SYSTEM FOR THE NORTHEASTERN STATES

In the map on the left hand of the page the white circles (A, C, D, F, H, I, J, L, N) represent the amount of power generated at points indicated; the gray circles (B, E, G, K, M, O) represent amount of power distributed to consumers from the points indicated, which are the principal distributing centers of the system. All circles are drawn to scale. The total amount of power supplied by this system exceeds 2,000,000,000 kw.-hr. a year, most of which is generated by water power.

In the map on the right hand of the page circle A represents the total undeveloped power of the St. Lawrence River lying wholly in Canada. B and C represent the undeveloped power of the border portions of the river belonging respectively to Canada and the United States. The light portions of D and E represent the amount of Niagara Falls power now being used by Canada and the United States; the dark portions represent the amount of Falls power proposed for early development. The inclosing dotted circle represents the total power of the Falls. Circles F to Q inclusive represent the amount of power now being generated and consumed at the points indicated. All circles are drawn to the same scale.

## President's Coal Commission Is Continued

While the continuance of the President's Coal Commission was imperiled by the delay in voting its appropriation, Congress in an eleventh-hour effort gave the commission all legislation which it had asked. This included the appropriation of $400,000, the authorization to require sworn answers to questionnaires, the extension of the life of the commission until Dec. 31, and the authorization for Judge Alschuler to serve as a member of the commission. Chairman Hammond said that he can foresee no contingency that will interfere with the submitting of the final report on Sept. 22. There is reason to think, however, that the commission is glad to have additional time made available to provide for delay.

## Charts Show Growth of Illinois Northern Utilities

To explain the meaning of its annual report for the year ended Dec. 31, 1922, the Illinois Northern Utilities Company used charts indicating annual growth from 1918. Gross earnings for 1922, including merchandise sales, were $2,129,276, which is an increase of $141,956 over 1921. For the same year the gross revenue from the sale of gas and electricity increased $198,088, or 12 per cent. Net earnings amounted to $707,685 as against $655,426 for 1921, an increase of $52,250. This increase would have been even greater had not the coal strike compelled the company to pay abnormal prices for coal during the latter part of the year. After paying $189,362.92 on preferred stock, a surplus remained of $111,473.69.

During the year 2,101 electric customers were added, making a total of 29,348. Stock sales to customers were continued, adding 491 stockholders and giving a total of 1,477 at the close of the year. In addition, 423 individuals were subscribing to the company stock on the monthly installment basis.

## Pacific Gas & Electric Has Big Year

The report of annual earnings issued this week by the Pacific Gas & Electric Company showed an increase of $1,694,898 in gross revenues and a gain of $2,557,107 net as compared with the previous year. The company's gross business during the year ended last Dec. 31 was $39,204,605 and balance available for common dividends was $4,013,003, or 11½ per cent.

The company's sales during the year reached 1,098,000,000 kw.-hr., an increase of 76,300,000 kw.-hr., or 7½ per cent, as compared with the previous year. The net addition of 46,295 customers during 1922 exceeded all former records. Total customers served as of Jan. 31 were 649,293.

The company's investment in plants and properties on Dec. 31 last stood at $200,250,877. On Dec. 31 last the funded debt was 56.53 per cent of the total capitalization. In 1922 15.3 per cent of gross and 38 per cent of net was required for annual interest on all outstanding bonds as against 25.9 per cent and 61 per cent respectively in 1921. The company has approximately $15,000,000 cash on hand, which it is anticipated will be sufficient to cover its capital requirements for construction work during the year.

## Hoover Calls Radio Conference for March 30

Inaction by the Senate having caused the radio control bill passed by the House of Representatives, as reported in the ELECTRICAL WORLD for Feb. 3, page 292, to fail, the House a few hours before the session closed adopted a resolution directing the Federal Trade Commission to investigate and report to the next Congress regarding control of radio patents. The bill that died in the Senate would have vested authority in the Secretary of Commerce to regulate transmission stations through a licensing system. Because of its failure Secretary Hoover on March 6 sent out invitations for a reassembly of the radio conference held a year ago, together with some additional members, to investigate what administrative measures may properly be taken temporarily to lessen the amount of interference in broadcasting. The conference will be held March 20 at 11 a.m. at the Department of Commerce, Washington.

## A. T. & T. May Increase Its Stock to $1,000,000,000

The directors of the American Telephone & Telegraph Company recommend in their annual report to stockholders for 1922, just issued, that the authorized share capital of the company, now $750,000,000, of which more than $699,000,000 was outstanding at the end of the year, be increased to $1,000,000,000 to take care of present commitments and future requirements. No new stock offering is, however, contemplated for 1923. With a billion-dollar capitalization, the company would rank all others in the country in share capital, the present leader, the United States Steel Corporation, having a total of $950,000,000.

Taking the American Telephone & Telegraph Company alone, without its associated companies, the report shows that in 1922, after meeting operating charges and making provisions for depreciation, obsolescence and taxes, it had available for interest and dividends $81,668,440. Interest charges were $15,498,012, a reduction of $4,023,097 from 1921, thus reflecting the reduction of $74,095,100 in the company's debt during the year. Dividends paid to stockholders at the rate of $9 per share per year amounted to $52,971,252, an increase of $10,296,849 over 1921, this increase being principally the result of an increase in the outstanding capital stock of $151,162,100.

## N. E. L. A. on Code Revision

**Objections to Addition to Rule 12-b to Be Made at Public Hearing of N. F. P. A. Committee**

AT THE public hearing of the electrical committee of the National Fire Protection Association next Monday, W. H. Blood will present objections of the National Electric Light Association to certain proposed revisions of the National Electrical Code. The requirement which is most objected to is the proposed addition to Rule 12-b, second paragraph, which reads as follows: "Line wires of voltage less than 5,000 volts between wires shall have an improved weatherproof or rubber-insulated covering." The National Electric Light Association requests that this proposed addition shall not be added to the code.

### WHY RULE IS OPPOSED

The reasons given for the objection are as follows:

1. The covering consisting of braidings and compound known as "weatherproof" covering is not an insulating material and should not be so described. The fact that this material was at one time considered to be an insulating material is not of present significance, considering the great advance in the knowledge of the properties of insulating materials made during the last few years.

2. It is current good practice among the electricity supply companies to warn all employees that covered wires are to be handled as though they were bare, and this practice is sound on account of the unreliable insulating properties of these coverings. It is only with the utmost difficulty that this wise provision is impressed upon the line workmen and others concerned, and therefore any official expression tending to support the idea that such materials are insulation will have the effect of weakening the earnest efforts made for the safety of line workmen and others.

3. Any slight temporary protection as actual insulation that may be afforded by new weatherproof coverings for line wires is usually more than offset by the increased wind and ice loadings which result from the greater diameter of the covered wire, whereby the lines are more liable to stretch or break and the supporting structures are more heavily loaded.

Attention is invited to the following quotation from the Bureau of Standards Handbook No. 4, "Discussion of the National Electrical Safety Code": "No requirements for provision of insulating coverings for conductors in overhead lnes of any voltage have been made. While such coverings are sometimes an aid in preventing burn-outs, the reduction of hazard derived from their use is problematical. Their use may even cause an added hazard for the higher voltages, as after being in service some years they deteriorate. Their use in this condition gives rise to a false feeling of security. Much

more reliable and effective safeguards against the danger from fallen and crossed wires are the provision of proper wire clearances and separations and the maintenance of these clearances and separations by suitable minimum conductor sizes, sags and strength of supports."

4. During the three years past, when the 1920 edition of the code contained no requirement for the use of weatherproof coverings on line wires, there has been no general tendency to discontinue its use for the purpose to which it was formerly applied, and this is good evidence that there is no desire on the part of the electricity supply companies to abandon this weatherproof covering in the situations where it is useful and appropriate.

5. The proposed voltage limitation of 5,000 is arbitrary and unrelated to any standard distribution voltage and to current good practice. It may have been intended at some former time to provide a figure for demarcation between "distribution" and "transmission" voltages, but if this was the case, it no longer has any significance in that connection or any relation to current good practice. It provides no reasonable line of demarcation between voltages for which covering has a large and only a negligible value.

6. Municipal and insurance inspectors are widely averse to such a rule, as shown clearly in the discussion at the recent meeting of the Western Association of Electrical Inspectors, where stress was laid on the rapid deterioration of line wire coverings and the false sense of security engendered by such coverings. Inspectors of state utility commissions, who deal much more generally with overhead lines both near to and remote from buildings, generally adhere to the provisions of the National Electrical Safety Code and do not require insulating coverings.

7. It is submitted that the applicable parts of the National Electrical Safety Code should govern in this case, no less than as provided in the proposed change in Rule 13 which every one supports and which reads: "It is advised . . . that the rules of the National Electrical Safety Code, Part 2, be followed."

8. Finally, it is believed that the proposed revision is entirely too sweeping in its effect and not justified by experience. Such a rule, if included in the National Electrical Code at all, should be drawn only after thorough study and full hearing of all interested parties; that has not been done in the present case.

## Another Bill Aimed at Indiana Commission Fails

A bill to enable cities on referendum vote to operate municipal utilities without jurisdiction of the Public Service Commission or to build a utility plant without obtaining its consent has failed in the House of Representatives of the Indiana General Assembly by a vote of 48 to 39. Three more votes would have given the bill the requisite two-thirds majority. A motion to postpone the bill indefinitely was lost, and it may be called up for third reading again at any time by any representative.

The same bill in the Senate is expected to come from committee with a divided report, the majority against it. It is thought to have small chance in the Senate. Governor Warren T. McCray will be vigorously against it.

## Federal Board Files Reply

### Amended Bill of Complaint of New York Contested in United States Supreme Court

SETTING up the claim that the federal government has authority over the Barge Canal system of New York under the interstate commerce clause of the Constitution, the canal system being a part of an interstate and foreign commerce waterway, Solicitor-General Beck has filed in the United States Supreme Court for the Federal Power Commission an answer to the amended bill of complaint entered by the State of New York to test the authority of the commission. In its amended bill the state had claimed that it had spent great sums on the development of waterways within the state and had projected hydro-electric developments concerning which it claimed the Federal Power Commission had no authority.

The commission's amended answer declares that the bill does not join essential parties in that no determination can be made of the authority of the United States to enter into contracts with citizens of New York for the acquisition of real or other property useful in the preservation or improvement of navigation in the absence of the citizens whose property is affected. The answer further claims that the state does not present any concrete plan regarding its proposal for hydro-electric development or show how such plans would affect navigation. It is pointed out that the United States government spends large sums for the development of navigation in the harbor of New York and on the Hudson River. The state has filed no plans for power development with the commission, the answer says, but private persons have, and these applications are being considered by the commission.

Regarding the state's announced contemplation of hydro-electric development on the St. Lawrence River, the commission's answer sets forth that this waterway has been the subject of an international conference by act of Congress looking toward its improvement for oceangoing transportation and that if the state were to make any effort to construct plants there the commission would seek action by the Attorney-General to determine the effect.

The Federal Power Commission itself does not construct plants, the answer continues, and such construction by those licensed to do so by the commission would not deprive the state of the right of taxing such properties.

## Arkansas Light & Power Gets Mississippi Properties

Announcement has been made by H. C. Couch, president, and J. L. Longino, vice-president of the Arkansas Light & Power Company, of their acquisition of the Jackson (Miss.) Public Service Company and the Vicksburg (Miss.) Light & Traction Company. The Jackson company operates the street railway, electric and gas systems in that city and formerly was controlled by the American Public Utilities Company of Grand Rapids, Mich. W. E. Brown of Jackson is the general manager. The Vicksburg company operates the street railway and the electrical systems in Vicksburg and was controlled by the Union Utilities Company of Chicago. E. S. Myers is general manager. It is understood that relinquishment of control of the Jackson properties by the Brewer interests and of the Vicksburg properties by the Elston interests is due to the fact that these were the only properties of these syndicates in the South.

In the reorganization of the Jackson and Vicksburg companies H. C. Couch will be president, J. L. Longino vice-president and general manager, W. E. Baker treasurer, and L. Garrett secretary. These, with C. P. Couch, manager of the Arkansas Light & Power Company properties at Arkadelphia and Malvern, Ark., will comprise the board of directors.

Improvements already started at Jackson will be carried out. A transmission line will be extended west from Jackson to Clinton, and it is probable that another line will be extended east from Vicksburg, interconnecting these two power stations. The Arkansas Light & Power Company will supply electrical energy to the American Bauxite Company for mining and drying bauxite and lighting the town of Bauxite, Ark.

## Oklahoma Is Seeking to Tax Utilities on Rate Valuation

Efforts are being made in Oklahoma to force public utilities to return for tax purposes the same property values that are fixed by the Corporation Commission for rate-making purposes. Several bills introduced with this object have been held unconstitutional by the Attorney-General. The judiciary committee of the House has introduced a bill designed to correct the defects in the previous bills. This provides that in all hearings before the commission to fix utility rates the state shall be considered a party adverse in interest to the public utility, and that before an order fixing rates is entered the commission shall enter a judgment fixing the value of the property. Where a report was filed by a utility showing the value of its property, the report would be considered as a confession of judgment and a commission order entered accordingly, except as the commission might desire to dispute the value reported.

## Convention Arrangements

**Advance Circular from the N. E. L. A. Headquarters Tells of Hotels and Transportation**

AN ADVANCE circular on the forty-sixth convention of the National Electric Light Association, to be held in New York City on June 4-8, has been issued by headquarters, and intending visitors are already being urged to secure their hotel accommodations by filling out a form inclosed and returning it to the hotel committee, N. E. L. A., 29 West Thirty-ninth Street, New York. A list of thirty hotels within a radius of a mile of the convention meetings is listed, with their rates. Joseph F. Becker is chairman of the hotel committee.

Convention headquarters will be at the Commodore Hotel, Forty-second Street and Lexington Avenue, immediately adjacent to the Grand Central Terminal, where the business sessions will be conducted, with additional facilities, if necessary, also provided in the Biltmore Hotel, adjoining. The first business sessions of the four national sections will convene early Monday afternoon, June 4, with other section sessions on the afternoons of Tuesday, Wednesday and Thursday. The first general and executive session will be held on Tuesday morning, June 5, with other such sessions following on Wednesday, Thursday and Friday mornings. The important session of the public policy committee will be held on Thursday evening, June 7, at Carnegie Hall, Seventh Avenue and Fifty-seventh Street.

#### Transportation

Godfrey H. Atkin, Electric Storage Battery Company, 713 Marquette Building, Chicago, has accepted the appointment of master of transportation. Mr. Atkin has already made application for a special round-trip rate of one and one-half fares from all points to New York City. A special round-trip fare from all Pacific Coast points to New York City of $147.40 has been agreed upon by the railroads.

It is the intention of the transportation committee to operate special trains from Chicago and Boston for the convenience of the Western and the New England delegates. The master of transportation will be glad to hear from any members who would like to have special trains or special cars operated from their particular sections of the country.

For special information not covered by the circular, A. Jackson Marshall, committee secretary, should be addressed at headquarters.

## Insufficient Grant May Hamper California Commission

Some concern is felt in California over the rigorous policy of economy of the new Governor as it affects the State Railroad Commission. The commission's allowance for the next two years is $793,000, which is $234,800 less than the appropriation made for the two years just past and $100,000 less than the minimum requirements estimated by the president of the commission. Ninety per cent of the burden of this cut in the budget falls on the engineering department, whose engineering staff will be reduced from fifty-two to twenty-four.

During 1922 there were 4,950 informal complaints made to the commission, virtually all of which were handled by the engineering department. To curtail the work of this department will, in the view of many, seriously reduce the commission's service to the public and will mean that it will either take a discouragingly long time to obtain the facts in a case or that only part of the facts will be obtained. A decision which is not based on full engineering investigation may, these men point out, be inequitable either to the public or the utility. Personal views of the commissioners might under such circumstances influence their decision, and it is not inconceivable that the commission might in time lose something of its present standing or even degenerate into a political body.

# Utility Commission Engineers Confer

**Discuss the Grading of Public Utilities in Conformity to Service Rules and Other Utility Problems and Lay Plans for Permanent Organization**

PLANS for an annual conference of engineers attached to the state utilities commissions, to be conducted under the auspices of the Bureau of Standards, were laid at a meeting at the Department of Commerce, Washington, on March 2 and 3. It was the consensus of opinion of the engineers of more than one-third of the state commissions that there should be an annual conference at which the technical and engineering questions involved in utility operation could be discussed in the interest of the common good.

#### Objects of Conference

This conference was called by Dr. F. C. Brown, the acting director of the Bureau of Standards. The conferences are to be along the lines of those which have been held for many years, in which the specialists of the bureau have met with the weights and measures officials of the various states with the idea of exchanging views and experiences. In addition to the benefits which will come from the exchange of views among the utilities engineers, it will give them an opportunity to obtain first-hand knowledge of the experiments and research which the bureau is conducting on the public utility problems.

Addresses were made at the meeting by representatives of the Bureau of Standards and by commission engineers. The topic chosen was "Grading Utilities in Conformity to Service Rules." An executive committee was selected to work out plans for future conferences. C. B. Hayden of the Wisconsin commission was chosen as the chairman of this committee, and E. C. Crittenden, chief of the electrical division of the Bureau of Standards, as secretary. Other members are William M. Black of the Maine commission, C. R. Vanneman of the New York commission and A. I. Thompson of the Oklahoma commission.

Other topics on which there was a general discussion were inductive interference and the grounding of electrical circuits. Secretary Hoover opened the conference.

In explaining the relationship of the Bureau of Standards to the conference Mr. Crittenden said:

"The bureau has aimed to do three things, first, to carry out experimental investigations of problems affecting the efficiency of operation, cost and quality of service rendered; second, to determine the facts with regard to actual practice, and, third, to combine the results of laboratory investigations and of field observations with the judgment of trained and experienced engineers so as to formulate recommendations or codes of practice which would safeguard the interests both of utility operators and of utility customers.

"It should be emphasized that the bureau does not seek or desire any authority to impose its findings on others. Its position as an impartial fact-finding and advisory body is believed to be the most useful one for a federal government agency in this field. Such success as the work has attained in the past would have been impossible without the cordial co-operation of utility companies and their associations as well as city and state authorities. The earlier work was done largely with city officials, but as the principle of state regulation has gained wider and wider acceptance, our contacts have naturally shifted to the state commissions."

#### Engineers in Attendance

Commission engineers who attended the conference were, by states: Alabama, I. F. McDonnell; Georgia, J. Houstoun Johnston; Illinois, J. Howard Mathews; Indiana, Earl L. Carter; Iowa, A. B. Campbell; Maine, William M. Black; Maryland, H. C. Wolf, W. F. Strouse, S. A. Covell, Mr. Cullen, L. Ellis, R. Y. Gildea and J. L. Wicks; Michigan, Manfred K. Toeppen; New Hampshire, D. Waldo White; New Jersey, Col. P. Betts; New York, C. R. Vanneman and R. H. Nexsen; Ohio, L. G. White and Ward Snook; Oklahoma, A. I. Thompson; Tennessee, F. G. Proutt; Virginia, J. W. West, Jr.; West Virginia, James Imboden and W. B. Hall; Wisconsin, C. B. Hayden; District of Columbia, E. G. Runyan, and Connecticut, A. E. Knowlton.

## City Ownership Is Agitated in Denver

Recent developments in Denver indicate that municipal ownership of public utilities will be one of the chief planks in the platform of several mayoralty candidates in the spring campaign. Governor Sweet is out with a statement that he will not favor any candidate who does not stand for this policy. During the term of the next Mayor the franchises of both the Denver Tramway Company and the Denver Gas & Electric Light Company will expire, and it is likely that the traction system, although in the hands of a receiver, will receive the first attack, with the central-station company second.

Both Governor Sweet and Frank N. Briggs, a prominent Denver banker who has announced his independent candidacy for Mayor, have declared their belief that regulation and control are positively unsuccessful. Many years have elapsed since a fight was waged against the public service corporations in Denver, and the results of the coming campaign will determine the character and intensity of the effort to be made by public utility companies in the near future for the acquisition of new franchises.

Mr. Briggs recently addressed the Denver Section of the A. I. E. E. in support of his views, taking as his subject "Possibilities of Denver as an Electrical City."

## Illinois Utilities to Hold Convention Next Week

A joint convention of the Illinois Gas, Illinois State Electric and Illinois Electric Railways Associations will be held at the Hotel Sherman in Chicago Wednesday and Thursday, March 14 and 15. At the joint morning sessions Charles M. Thompson, dean of the College of Commerce and Business Administration, University of Illinois; Ralph E. Heilman, dean of the Northwestern University School of Commerce; Martin J. Insull, vice-president Middle West Utilities Company; Britton I. Budd, president Chicago Elevated Railroads; E. W. Lloyd, chairman Joint Committee for Business Development; George R. Jones, chairman public speaking bureau of Illinois Committee on Public Utility Information; E. Hill Leith of Halsey, Stuart & Company, and B. J. Mullaney, director Illinois Committee on Public Utility Information, will speak.

The program of the electric section of the convention follows: "Survey of Appliances and Their Use in Residences in Chicago," H. B. Gear, Commonwealth Edison Company; "Development of the Mazda Lamp, Introducing the New 30,000-Watt Lamp," F. T. Benson, General Electric Company; "Unattended Distribution Substations of the Commonwealth Edison Company with Remote-Controlled Automatically Regulated 4,000-Volt, 60-Cycle Circuits," H. E. Wulfing, Commonwealth Edison Company; "Alternating-Current and Direct-Current-Controlled Automatic-Feeder Substations," F. E. Goodnow, Public Service Company of Northern Illinois; reports of committees on uniform classification of accounts and customers' records and billing; "Correct Meter Installation and the Use of Protective Devices Against Thieving," R. D. Hart, Central Illinois Light Company; symposium: "Merchandising Domestic Appliances," R. S. Bell, United Appliance Company; "Commercial Appliances," "Convenience Outlets," Electrical Home," representatives of Commonwealth Edison Company.

## Best Definitions of Courtesy to Win Prizes

An unusual feature of the convention of the Oklahoma Utilities Association to be held at Oklahoma City on Monday to Wednesday of next week will be the awarding of first and second prizes for the best definitions of "courtesy to the public" from the public utility operator's standpoint. Answers are limited to twenty-five words, and five replies, selected by a committee of three, will be voted on at Wednesday morning's general meeting. E. B. Smith is in charge of the contest.

The electric light division of the association, meeting on Tuesday afternoon, will hear addresses by R. G. Tyler, dean of the Agricultural and Mechanical College, Stillwater, Okla., on "The Relation of the School of Engineering to Utilities;" by B. P. Stockwell of the Oklahoma Corporation Commission on "Commission Regulations Governing Rate Changes," and by W. D. Riggs, Oklahoma Gas & Electric Company, on "Meters and Theft of Energy." Martin J. Insull will address a general session on Monday afternoon on "The Public's Interest in the Public Utilities." On Wednesday to Friday the Southwestern Geographic Division, N.E.L.A., will meet, its Wednesday sessions being held jointly with the Oklahoma Utilities Association. Expected speakers were named in the "Associations and Societies" column last week, page 538.

## Additional Hydro Development in Arkansas

The beginning of actual construction work by this month on a hydroelectric development that will have an ultimate capacity of 120,000 hp. is announced by the Caddo River Power & Irrigation Company of Little Rock, Ark. The company has received permission from the Federal Power Commission to construct a dam on the Ouachita River at what is known as the Remmel site, south of Hot Springs. It has already a license covering two other sites, but work is beginning on the dam just authorized. This dam will develop 15,000 hp. at an estimated cost of $2,000,000, and the plant is expected to be in operation in eighteen months.

By a contract with the Arkansas Light & Power Company, the energy from the new development will be distributed largely through the system of that company. The Arkansas Power & Light Company already has a 66,000-volt transmission line from Picron, near Little Rock, to Malvern, connecting with the Malvern-Arkadelphia system. The new plant will be connected with this tie line. The William Crooks Engineering Company has formulated the plans for the development. Ford, Bacon & Davis are consulting engineers. The financing arrangements have been underwritten by a syndicate of western New England and Chicago bankers, according to announcements from the Pine Bluffs headquarters of the Arkansas Power & Light Company.

## Brief News Notes

**Urbana, Ohio, Has Successful Show.**—Urbana, Ohio, with a population of 7,600, closed its first electrical show with such success that the promoters plan to make it an annual affair hereafter. Paid admissions during the two days, Feb. 22 and 23, totaled 2,343.

**A Maryland Merger.**—The Maryland Public Service Commission has authorized the American Water Works & Electric Company of New York to assume control of the Cumberland Edison Electric Company, which was a recent merger of the old Cumberland Edison Electric Illuminating Company and the Cumberland Electric Company.

**University of Colorado to Give Meter Course.**—The electrical department of the University of Colorado will, through the electrical standardizing laboratory, furnish a course for metermen in the week of March 19-24. Intensive laboratory work, lectures and round-table discussions will be given. This will be the first time a meter course has been provided at the University of Colorado, but success will lead to its being made a yearly event.

**Electrical Alumni Gather at Milwaukee.**—Electrical engineers from all over the United States met in Milwaukee on March 1, 2 and 3 to participate in the "homecoming" of the alumni of the College of Electrical Engineering of the School of Engineering of Milwaukee. Bryce Tolbert of Greenwood, S. C., was chairman of the homecoming, and Arthur Richards of Brockport, Pa., was secretary and treasurer.

**Scholarships in Electrical Engineering.**—Two universities have recently announced the establishment of new scholarships in electrical engineering. Columbia has placed at the disposal of the A. I. E. E. a scholarship in its School of Mines, Engineering and Chemistry which pays $350 for annual tuition fees. Stanford University announces the Elwell scholarship, founded by Cyril F. Elwell, which carries a sti-

pend of $500 in its electrical engineering department.

**Flashboard at Neenah Dam, Wis., Ordered Removed.**—Efforts are being made by the Wisconsin state government, the Association for Relief of High Water and the water-power interests to agree upon a permanent co-operative plan by which flood conditions may be relieved in the Fox River Valley. The water-power companies are vitally concerned because the Secretary of War has ordered the removal of the flashboard from the Neenah dam and this flashboard is said to effect a saving in fuel to them of $180,000 a year.

**Work on St. Croix Development Begun.**—The first work by the Northern States Power Company to develop the water power of the upper St. Croix River has just begun. Camps have been built, and a crew of men is making an area survey of the river bottoms, which it is expected will take the greater part of this year. The power dam will be erected at the mouth of Snake River. A large reservoir dam will also be built at the head of the Kettle River rapids.

**Federal Court Protects Emergency Rates of Wisconsin-Minnesota Company.**—A preliminary injunction restraining the Wisconsin Railroad Commission from interfering with the existing emergency rates of the Wisconsin-Minnesota Light & Power Company has been issued by the United States District Court at Madison. These rates were necessitated by the decision of the Wisconsin Supreme Court annulling the order of the commission which fixed uniform rates on the company's "loop" system and ordering that they be determined for every city on the unit plan. The emergency rates were adopted by the company until the commission can fix permanent rates in accordance with the order of the state court.

**Dispute Over Rights on Coosa River.**—A storm is brewing in Alabama over the water-power project at Lock No. 2 on the Coosa River. One bank at that point is owned by Roswell Cobb. The other bank belongs to the government. The Alabama Legislature, in which there is some hostility to the Alabama Power Company, is expected to adopt legislation which will extend Cobb's rights. If this legislation is approved, plans are being considered, it is said, whereby the cities of Birmingham and Anniston will attempt to secure rights as municipalities through an arrangement with Cobb. The Alabama Power Company two years ago filed on the site, and it is anticipated that it will not give up its contemplated development without a struggle.

**Way Cleared for Large Water-Power Developments in North Carolina.**—The bill in the North Carolina Legislature dealing with "eminent domain" and sponsored by the water-power interests has been passed, and the way is now clear for the greater water-power projects to proceed to condemn and fix by court proceedings the price at which lesser water-power developments should be bought. The legislation was thought to be necessary because nuge dams being erected across the rivers were putting smaller dams for long distances up the rivers out of business, and where the parties at interest could not agree on purchase price or damages, development was sometimes blocked. The new law gives power to condemn the affected property and pay assessed price or damages.

**United States Supreme Court May Refuse Jurisdiction of Potomac Company Case.**—Arguments were presented before the United States Supreme Court Feb. 26 and 27 on the question of the jurisdiction of that court to review the decision of the District of Columbia Court of Appeals reversing and remanding for further proceedings a ruling of the District of Columbia Supreme Court which dismissed an injunction sought by the Potomac Electric Power Company against the District Public Utilities Commission to set aside valuation of the company's property for rate-making purposes. Arguments on the appeal were begun before the Supreme Court on Jan. 24, but were interrupted by Chief Justice Taft, who asked the attorneys to submit briefs on the court's jurisdiction. Attorneys for both the company and the commission argued that the court had jurisdiction, both sides being anxious to have the case passed on by that tribunal.

## Associations and Societies

**New Section of Institute Organized.**—The Southern Virginia Section, A. I. E. E., has been organized at Richmond, Va., with W. C. Bell as chairman and H. C. Leonard as secretary of the executive committee.

**Special Libraries Association.**—The Special Libraries Association, which is a national organization of all business and special librarians in the country, will hold its fourteenth annual convention in Atlantic City on May 22 to May 25, at the Hotel Chelsea. Librarians, business men, research workers and statisticians are urged to attend.

**Sioux City Electrical Club Formed.**—About seventy electrical men of Sioux City, Iowa, have formed the Sioux City Electrical Club. The purpose of the club is primarily educational. Membership is open to any one interested in electrical development. C. E. Murphy, superintendent of the Sioux City Service Company, was elected president. Other officers are: E. A. Artz of the Sioux City Electrical Construction Company, vice-president, and Elmer A. Croll, secretary and treasurer.

**Engineering Society of Wisconsin.**—Meeting at the University of Wisconsin, Madison, on Feb. 22 to Feb. 24, the Engineering Society of Wisconsin went on record as favoring a bill which would create a board of examiners of architects, engineers and land surveyors to consist of the state architect, the state chief engineer, the dean of the engineering college of the university and three engineers in good standing, all to be appointed by the industrial commission. The bill will be presented to the Legislature. Officers elected were: President, John C. White, Madison; vice-president, D. G. Kirchhoffer, Madison; secretary-treasurer, L. S. Smith, Madison.

**Coming Section Meetings of A. I. E. E.**—March section meetings of the A. I. E. E., in addition to those listed in this column on Feb. 24, are announced as follows: Baltimore, March 18, "Wired Wireless," R. D. Duncan, Jr.; Boston, March 30, "History of Artificial Illumination," M. Luckiesh; Chicago, March 19, "Industrial Research," C. E. Skinner; Cleveland, March 22, "Motors, Bearings, Brakes, Clutches, Control," A. M. MacCutcheon; Minneapolis, March 16, "National and International Standardization," C. E. Skinner; Pittsfield, March 15, "Vacuum Tubes and Their Application," Irving Langmuir; Rochester, March 23, "Relay Protection," Mr. Hunting; Seattle, March 23, "Power-Factor Correction," F. F. Ambuhl; Washington, March 13, "Electrical Equipment on Automotive Vehicles," J. H. Hunt.

### Coming Meetings of Electrical and Other Technical Societies

[A complete directory of electrical associations is published in the first issue of each volume. See Jan. 6 issue, page 78, for latest list.]

Oklahoma Utilities Association—Oklahoma City, March 12-14. O. D. Hall, 1106 First National Bank Bldg., Oklahoma City.

Southwestern Division, N. E. L. A.—Oklahoma City, March 14-16. S. J. Ballinger, San Antonio Public Service Co., San Antonio, Tex.

Illinois State Electric Association—Chicago, March 14-15. R. V. Prather, 305 Mine Workers' Bldg., Springfield, Ill.

Wisconsin Utilities Association—Milwaukee, March 22-23. John N. Cadby, 445 Washington Bldg., Madison.

Middle West Division, N. E. L. A.—St. Louis, April 11-12 H. M. Davis, Bankers' Life Bldg., Lincoln.

Tri-State Water and Light Association—Birmingham, April 17-20. W. F. Steiglitz, Columbia, S. C.

American Physical Society—Washington, April 21. D. C. Miller, Case School of Applied Science, Cleveland.

American Institute of Electrical Engineers—Spring convention, Pittsburgh, April 24-26; annual convention, Swampscott, Mass., June 25-29; Pacific Coast convention, Del Monte, Cal., Sept. 25-28. F. L. Hutchinson, 33 West 39th St., New York.

American Electrochemical Society—New York, May 3-5. Colin G. Fink, Columbia University, New York.

Southwestern Public Service Association—Fort Worth, Tex., May 15-17. E. N. Willis, 403 Slaughter Bldg., Dallas, Tex.

Electrical Supply Jobbers' Association—Executive committee and general meeting, Hot Springs, Va., May 21-25. Franklin Overbagh, 411 S. Clinton St., Chicago.

Missouri Association of Public Utilities—River boat from St. Louis to Peoria, May 24-26.

American Society of Mechanical Engineers—Montreal, May 28-31. C. W. Rice, 29 West 39th St., New York.

National Electric Light Association—New York, June 4-8. M. H. Aylesworth, 29 West 39th St., New York.

Ohio Electric Light Association—Cedar Point, June 10-13.

Electric Power Club—Hot Springs, Va., June 11-14. S. N. Clarkson, Kirby Bldg., Cleveland.

Pacific Coast Electrical Association—San Francisco, June 19-22. S. H. Taylor, 527 Rialto Bldg., San Francisco.

Canadian Electrical Association—Montreal, June 20. Louis Kon, 65 McGill College Ave., Montreal.

American Society for Testing Materials—Atlantic City, June 25-29.

National Council Lighting Fixture Manufacturers—Hot Springs, Va., June 26-28.

# Recent Court Decisions

**Prior Franchise Gives Exclusive Right to Space Occupied by Lines.**—In modifying or interpreting its finding in the inductive interference case of Phillippay vs. Pacific Power & Light Company (ELECTRICAL WORLD, Aug. 12, 1922, page 345, and Jan. 6, 1923, page 56) the Supreme Court of the State of Washington declared that, though the holder of a prior franchise has no exclusive right to the occupation of a street, it does acquire a right, which is in the nature of an exclusive one, to the continued occupation of the space occupied by its poles and wires, subject to proper control by public authorities, and this right must be recognized by the subsequent company in the construction of its line. (211 Pac. 872.)*

**Responsibility for Fatality Shared by City and Railroad.**—In Carroll vs. Atlantic Coast Line Railroad Company and City of Ozark damages for the death of a pedestrian who came in contact with an electrically charged guy wire were sustained by the Supreme Court of Alabama, which held the defendants equally culpable. The railroad company, which purchased energy from the city plant, had strung a wire on a post to brace which a guy wire and post were maintained by the city, and evidence showed that the lighting wire had become worn and uninsulated for several weeks before the accident and in danger of contact with the guy wire and that the guy post was loose. It was for the jury to decide whether the victim was guilty of contributory negligence in touching or grasping the guy post or guy wire. (94 So. 820.)

**Erection of Dam Authorized by Legislature Cannot Be Held a Nuisance.**—Charging that the backwater from a dam erected by the Wateree Power Company had formed stagnant pools and provided a breeding place for mosquitoes to the injury of the land and the spread of malaria, the plaintiff in Belton vs. Wateree Power Company obtained damages of $2,000 in the trial court. This verdict has been reversed by the Supreme Court of South Carolina, which holds that an individual not suffering peculiar damages from a nuisance prevalent in the whole community cannot recover, the injury, if any, being a public one. However, the court continued, assuming that the breeding of malaria-bearing mosquitoes is incidental to the construction of a dam authorized by the Legislature, this authorization prevents the dam from being considered as a public nuisance subjecting the company to indictment. In the absence of negligence in the construction of the dam, the only recourse lies in action for compensation. One conveying a part of his land to defendant to be flooded by a dam had impliedly consented to defendant's entry on the land, and even though entitled to recover consequential damages to other lands, if there had been no entry, is limited to an action for compensation under the statute authorizing the construction of the dam. (115 S. E. 587.)

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

**Possibility of Raising Dam No Excuse for Backing Up Water Below Dam.**—Harp vs. Iowa Falls Electric Company was an action in equity to enjoin defendant company from maintaining its dam at such a height as to back the water up at plaintiff's dam and mill, and thus destroy or infringe upon plaintiff's right to the fall of the water. The Supreme Court of Iowa, affirming a decree for the plaintiff, held that the possibility that a riparian owner may increase the height of his dam, and therefore obtain the same head of water, does not justify the act of the lower owner in backing up the water on the wheels of the upper owner, especially where the upper owner's statement that his attempt to raise the dam had been objected to by those above him was not denied. Neither did the fact that the owner of a dam could secure enough power to operate his mill with a lesser head by installing more efficient wheels justify the lower owner in the course complained of, since the upper owner is entitled to the intrinsic value of his entire right of fall. The cost to the company of reconstructing its dam was found not so disproportionate to the damage caused to the upper owner as to defeat the right of the latter to an injunction. (191 N. W. 520.)

**Indiana Commission Sustained in Indiana Electric Corporation Case.**—Sustaining the demurrer of the Indiana Electric Corporation in the suit brought by the cities of Indianapolis and Kokomo against the Public Service Commission, the Indiana Electric Corporation and others to prevent the merger of seven Indiana utility companies, the Supreme Court of Indiana said, among other things, that where the Public Service Commission has jurisdiction and keeps within it, and its action is not vitiated by fraud, its decision of all questions of fact as to value of the properties of public utilities, sufficiency of the income to pay interest and dividends on bonds and stocks authorized, qualifications of a proposed purchaser, and all other questions which it is required to decide as preliminary to taking action in a proposed purchase by a corporation of public utilities, is conclusive upon the courts in a collateral action; that the mere averment that the property is only of the value of $10,300,000, but that the commission, after hearing conflicting evidence as to such value, found it to be worth $17,500,000, does not charge fraud, and that a complaint which does not show by the facts alleged that the Public Service Commission was without jurisdiction nor the order complained of fraudulent is not sufficient to constitute a cause of action. (137 N. E. 705.)

# Commission Rulings

**Taxing Customers for Extensions.**—Holding that a contribution from prospective customers to the cost of extending the lines of the nearest central-station company to Bloomfield was a prerequisite to service, the Utah Public Utilities Commission said: "If the revenue derived from a particular consumer in relation to the special investment made to serve him is not a reasonable amount, then such consumer becomes a burden upon the general consuming public and the service to him constitutes unlawful discrimination. Hence it is that consumers at too great a distance from existing lines or having peculiar conditions of taking service are required to share in the special investment made to serve them."

**Location of Service Extensions.**—A complaint brought by the C. L. Dooley Company against the Brooklyn Edison Company arose through a dispute over the location of the service entrance on the premises of the complainant, the complainant contending that the defendant should supply the electric service underground, while the Brooklyn Edison Company made the contention that service should be accepted at an existing inlet already on the wall of an inclosed alley or driveway at the complainant's premises. The commission dismissed the complaint, holding that service given to the owner of the premises at one service point through an electric meter properly located is sufficient and that any new electrical construction on the premises should be run to that point.

**Original or Reproduction Cost.**—In adopting original cost rather than reproduction cost as the measure of value in fixing rates for the Exeter Waterworks, the New Hampshire Public Service Commission said: "Reproduction new values and depreciation values are entirely matters of estimate, and the results obtained depend wholly upon assumptions. An expert will advance convincing arguments why his assumption is correct, and another expert will give equally convincing reasons why *his* assumption is correct, yet the results derived from these assumptions may be and usually are very different. This is not said in derogation of experts, but the fact is that their opinions are of very little help to the commission for the reason that opposing interests can always obtain experts to sustain their side of the case, regardless of how irreconcilable their conclusions may be with the conclusions of the opposing experts. For that reason, if for no other, in fixing values the historical cost of a plant is always more satisfactory than the reproduction cost. One is based upon facts, while the other is based upon estimates which at most are only intelligent guesses."

# Men of the Industry

Changes in Personnel
Accomplishments, Responsibilities, Honors, Appointments and Activities of Men Engaged in all Branches of the Electrical Industry

## D. H. Foote Third Vice-President of P. G. & E.

D. H. Foote, secretary of the Pacific Gas & Electric Company since 1907, has received the title of third vice-president of the company in addition to that of secretary. Mr. Foote is a native of Philadelphia, and much of his business experience, which was along banking lines, was gained in the position of secretary and treasurer of the Union Trust Company of that city. He went to California in 1901, and upon the organization of the California Gas & Electric Corporation, in 1903, he became its first cashier and assistant secretary. In 1905 the Pacific Gas & Electric Company was organized, and in July, 1907, Mr. Foote was elected to the responsible position of secretary. In 1909 he was elected a member of the board of directors and later was also appointed assistant treasurer.

## F. F. Rossman Leaves Westinghouse Company

Frank F. Rossman has resigned as division manager of the Westinghouse Electric & Manufacturing Company at Kansas City to become vice-president and general manager of the Mobile (Ala.) Light & Railroad Company. Mr. Rossman has represented his company in the Kansas City territory for the last eight years and has gained wide esteem and popularity. He had completed his twenty-third year of service with the Westinghouse company and in that time became thoroughly acquainted with railway matters. Friends of Mr. Rossman gave a dinner in his honor at the Hotel Baltimore, Kansas City, on Feb. 22. He assumed the duties of his new office on March 1.

F. A. Bryan, president of the Indiana & Michigan Electric Company of South Bend, Ind., has offered his resignation to the board of directors, to be acted upon at a meeting of the board to be held in New York in April. Mr. Bryan took this action shortly before departing for San Francisco en route to Hawaii, the Philippines, China, Japan and Korea. He will be gone several months. Mr. Bryan has completed twenty-two years of service with the company.

H. E. North, for many years connected with various Byllesby companies, has been transferred from the Oklahoma Gas & Electric Company at Oklahoma City to the Western States Gas & Electric Company at Stockton, Cal. Mr. North was in the stock sales department at Oklahoma City for several years and now takes charge of the Western States Gas & Electric Company's investment department. H. K. Griffin, who has been connected with the electrical industry in California for the last few years, has been appointed commercial agent in charge of new business for the Western States Gas & Electric Company.

## Ready Succeeds Sachse on California Commission

Lester S. Ready has been appointed chief engineer of the California Railroad Commission to succeed Richard Sachse, who has resigned to practice as a consulting engineer. The appointment became effective March 1. The new chief engineer has been associated with the Railroad Commission more than nine years, having been assistant chief engineer in charge of the gas and electric department four years. He is a native of Ventura County and a graduate of the University of California College of Electrical Engineering, class of 1912. Since graduation Mr. Ready has been actively engaged in engineering, specializing on public utility regulation. He entered the service of the Railroad Commission of California on Dec. 1, 1913, in the gas and electric division. On Jan. 1, 1918, he became gas and electrical engineer in charge of electric and gas service, rates and valuation. In October, 1919, he was advanced to the position of assistant chief engineer in addition to being in charge of the gas and electric division of the commission, which position he has held since.

L. S. READY

Richard Sachse had been with the commission since 1912 and since 1914 had held the position of chief engineer. He was graduated in civil and structural engineering in 1900 and then was engaged in railway, hydraulic, electric and harbor engineering work in West Africa, Belgium, Germany and Norway and later in the United States. Since 1903 he has been connected in an engineering capacity with the Western Electric Company, United States Steel Corporation, United States Reclamation Service and the Southern Pacific Company. He was recently appointed chairman of the engineering advisory committee to the National Association of Railway and Utilities Commissioners in connection with valuations now being made by the Interstate Commerce Commission. His work as chairman of the inductive interference committee is well known to the electrical industry. After leaving the commission his first work will be a comprehensive investigation of the street-railway situation in Los Angeles with a view to bringing about a unification of the two local systems.

The commission has appointed A. V. Guillou as assistant chief engineer in charge of the gas and electrical division of the commission. Mr. Guillou, who, like Mr. Ready, is a graduate of the University of California College of Electrical Engineering, class of 1912, has acted as assistant engineer in the gas and electric division for the last three years.

# Obituary

James Howard Zigler, manager of the lamp sales department of the Westinghouse Electric International Company, died at the Lexington Hospital, New York City, on Friday, Feb. 23, after a short illness, diagnosed by the doctors as sleeping sickness. Mr. Zigler was born in Columbus, Ohio, in 1890, and became associated with the Westinghouse Electric & Manufacturing Company at East Pittsburgh in 1917. Four years later he was transferred to the price department of the Westinghouse Electric International Company with headquarters at New York, and just before his death was made manager of the lamp sales department.

David Augustus Decrow, manager of the waterworks department of the Worthington Pump & Machinery Corporation, died in East Orange, N. J., on Thursday, Feb. 15. Mr. Decrow's association with the company dates back to the early eighties, when he joined the Holly Manufacturing Company as a mechanical draftsman. His promotions were rapid, and in 1903 he was made secretary of the company. Later the Holly Manufacturing Company was combined with the Snow Steam Pump Works at Buffalo as part of the International Steam Pump Company, and Mr. Decrow went to Buffalo to take charge of the pumping machinery. The International Steam Pump Company was succeeded by the Worthington Pump & Machinery Corporation in 1916. Not long after the change Mr. Decrow was called to the head office in New York as manager of the waterworks department, which position he held at the time of his death.

## Systematic Selection of Employees

**Fundamental Considerations that Should Be Observed in Hiring Help—Studying the Job—Analyzing the Applicant**

By Joseph Willits
University of Pennsylvania, Philadelphia

NO BUSINESS organization can be stronger or better or more successful than the individual men and women who are employed in it. The character of the company is the character of the people who represent it. The development and progress of the company cannot advance beyond the capacity of the personnel to grow with it. There is no point, therefore, at which the effectiveness of the whole organization may be so readily influenced as at the point where the selection of employees is made.

There have been many books written about "hiring and firing," and many quack methods have been presented whereby character may be determined and competent service assured by testing the color of the eyes, the thickness of the lips or the bumps on the brow. I have no faith in this. But as the result of a number of years of study, combined with our experience in hiring about six thousand persons for Uncle Sam during the war, I have the greatest faith in the systematic selection of employees by the practical exercise of ordinary care and common sense and scientific methods. And there are certain fundamentals of such intelligent selection that may be readily classified and easily applied.

### System Needed in Hiring

In the first place, for any industry and any organization, employment should be centralized so that those who do the hiring for the company may become expert in it. By this I mean not only expert in the judgment of character but skilled in the judgment of the job as well and in the maintenance of the standards and policies of the house. For when the hiring is left to each department head to choose his own assistants it is done in odds and ends of time by any method that suits him, and the result is a hit-or-miss policy with no governing purpose nor central control. To hire intelligently requires a very systematic process of adaptation and proficiency and can only be attained through experience and aptitude.

Before all else, it must be known what kind of an employee is needed for the job in prospect, and in order to be sure a careful detailed statement of the qualities desired should be drawn up. This statement should be prepared by the person who is to do the hiring, for it forces him out into the factory or the department to learn the labor problem and it helps him to give the applicant a clear idea of the job. It avoids either overselling or underselling the job, which would become a source of unrest. For too often the desire in the part of eagerness to fill the position leads to the painting of a too rosy picture.

The statement mentioned above should embrace:

1. A careful description of the work; the job that leads to it and the job that it leads to; responsibility, permanence, pay, hours, overtime; whether it requires an alert or a placid person; operations, machines, tools, postures, speed, disagreeable features, causes of common objection, sources of supply.

2. Description of the employee wanted; sex, race and nationality, language, education, physical and personal qualities, age limits.

To draw up such a specification requires a close study and contact with the work of the organization and intelligent knowledge of the personnel. The man who hires must know not only the kind of an employee who is needed and what kind of a job must be filled, but where the man or woman for the job can be found. He must be in a position also to guide in the training of men for promotion, for it is far better to find material within the organization, if possible, on account of the influence it exerts on ambition and slackness. But he must also know the outside sources of labor. He must have his work organized so that he may maintain a "prospect" file. He should receive his acquisitions sufficiently in advance to have time to draw from his classified "prospects" and not merely "hire at the gate." This also gives the person hired time to consider the job and give proper notice to the employer for whom he is working.

### Four Practical Tests

The person who does the hiring must be approachable, sympathetic and a judge of human nature. He must have maturity, education and experience in the industry. He must have a place provided so that the interview may be held in private. He must proceed with the examination of each prospective employee with systematic thought and thoroughness, testing the applicant in accordance with the nature of the job to be filled. There are four tests that can be applied in the classifying of prospective employees and adapting them to jobs that must be filled. They are:

1. Health test. Its purpose is not to eliminate but to guide and aid employment by setting applicants into four classes: (a) Health all right for any job; (b) health right for some definite class of work; (c) health adequate for certain work, but needs attention as to throat, heart, etc.; (d) a small group with health dangerous to other members of organization.

2. Trade test — of limited use, where trade information is a factor in the job. It serves to sort out novices, apprentices, journeymen, experts.

3. Mental test—for alertness, intelligence, character.

4. Physical test — to determine special ability and fitness, speed, alertness, strength, endurance, sight, hearing, nerve poise.

Such tests, however, should be used only to assist the judgment of the hirer, for systematic, painstaking common sense and thoroughness must be the foundation of it all. Intelligent discrimination comes out of experience, and in any organization it pays to take the job of hiring seriously enough to approach it in this way and make it a chief function of the one best fitted in the organization to do that work. The degree to which the physical and mental tests may be carried depends somewhat on the size of the organization and the amount which can be expended on expert assistance for the employment official.

The principle of intelligent selection, however, may be applied in any case in any business and deserves more attention than it usually receives.

That this applies as well in the electrical industry as elsewhere is evidenced by a recent statement by J. W. Bancker, assistant vice-president of the Western Electric Company, Chicago. He said:

> During the past few years the application of scientific analysis to the problem of industrial management has occupied the attention of many companies. This analysis has been largely directed to the solution of the problem as it was affected by the factors of materials, processes and equipment, and while it has been recognized that the study of the human element is at least as important as the other elements involved, comparatively little analysis of this factor has been attempted in comparison with the thought and study directed to the others.*

*Annals, American Academy of Political and Social Science, May, 1916.

# The Matter with Bill Jones, Contractor

### A Little Close-up of the Man on Whom the Electrical Industry Is Waiting to Develop the Market for Electrical Appliances—What the Manufacturer and the Jobber Must Do

By J. Eugene Chrisman
Dallas, Tex.

THERE is a good deal the matter with Bill as a retailer of electrical appliances, but only part of it is his fault. Most of it is the fault of the industry he is connected with. If Bill Jones is asleep on the job, what of the jobbers and the manufacturers that serve his territory?

If Bill Jones has eleven "Sloshwell" washers collecting dust in his warehouse, whose fault is it? What sold them to Bill? Not the fact that he needed washing machines. Not much. The thing that sold those washers to Bill was the fact that the "Sloshwell's" so-called "dealer helps" looked as though they would produce results and move the goods. Bill may not be a merchandiser, but he knows that the profit on washing machines, so far as he is concerned, begins only when they are out in homes washing clothes.

#### "Campaign" Experience

Bill did have the agency for a good vacuum cleaner too. One day he received a letter stating that if Bill felt that a good live vacuum-cleaner campaign would help in his town, the manufacturers would be glad to send a crew of trained salesmen to conduct such a campaign through his store. Bill bit! In due course of time the "crew" arrived. The company sent a letter to most of Bill's customers stating that "they had been selected by the Jones Electric Shop" for a free demonstration and trial of the cleaner Most of the folks in Centerdale, knowing Bill to be on the square and feeling that he was behind the campaign, accepted the free trial. The crew stayed two weeks and "sold" sixty-one cleaners. The first week one of the salesmen jumped his board bill and departed between days, bringing down the wrath of the widow Elkins upon Bill's innocent head. A week after the departure of the crew numerous customers who had "bought" cleaners began calling Bill on the phone. It developed that most of the "sold" machines had been merely left with the customer on the pretence of a thirty days' trial and no money paid down. They had signed monthly-payment agreements on this pretext, which had been turned in to the company as a bona fide sales, the "crew" having been engaged in a prize contest and each out to win. Bill suffered in silence, vowing never again!

What Bill Jones needs is real factory and jobber co-operation. Instead of gaudy window displays that are never displayed and broadsides that are never broadcasted, he needs selling campaigns that sell goods, Bill Jones must be sold the idea that if he wants business he must go after it and then be shown how to do it. Bill Jones needs resale assistance that will involve the personal aid and guidance of trained factory resale men, on the ground and not in an envelope.

Will it pay to put a man on the ground to show Bill Jones how to sell? Decidedly yes! Within a distance of 10 miles from Bill's store, waiting for good selling methods to gobble it up, lies approximately $20,000 worth of vacuum cleaner business alone. There is possibly $30,000 worth of small appliance business to be written on irons, heaters, percolators, toasters and fans alone! It is surely worth the time of any washing-machine manufacturer or jobber to begin working on the fifty-thousand-dollar washing machine market in his territory. In addition to this there should be not less than $20,000 on ironers and $10,000 on dishwashers, considering only the better class of homes as prospects for these appliances.

#### Key Log in the Jam

Jobbers and manufacturers are asking daily, "What's the matter with Bill Jones?" Bill Jones is all right. He's waiting—waiting for some one to come along and show him how to do it. He's waiting for some one to show him that he's sitting on a gold mine. He is all set to go. He is established in his town. Everybody knows Bill; he's been square with them; their children go to school with his; he belongs to the same lodge as most of them. Of course, if Bill had the enterprise he should have, he would undoubtedly have figured out a way to take advantage of this gold mine of his by himself. It's really too bad that he hasn't done it, for it would have saved the electrical industry a lot of trouble, but since Bill is just Bill there's no use lamenting the fact. The thing to do is wake him up.

The big problem not only of the electrical business but of every other business is turnover. In the electrical industry the problem starts with Bill Jones and goes right on up through the jobber's establishment and into the factory. Bill Jones is the key log in the jam. Show Bill how to move goods and you break the jam that holds back profits and production. Its regrettable that Bill has to be educated into an electrical merchandiser; he should do it for himself. But he doesn't.

Let's educate him to the fact that if he wants business he must go after it. Let's educate him to the fact that the home and not the display room is the place to sell appliances. Let's educate him to the fact that no new home should go up in his city without him being on the ground to figure on modern wiring and fixtures and a complete equipment of household appliances. Let's show him why a home builder, putting up a home at a cost of, say, $8,000, can be sold $500 worth of appliances before the house is erected, making it $8,500, easier than he can after he's moved in.

Let's show him how to keep card files that keep him posted on the electrical needs of his territory. Let's show him how to use any one appliance as an entering wedge and how to follow up on it until he's sold full equipment. Let's show him how to put on and train a couple of outside house-to-house men and let's help him train them. Let's instill into Bill Jones the "Sell 'em something more" idea. Let's realize that a dozen washers, cleaners or percolators gathering dust in Bill's store mean no more washers, cleaners or percolators on the jobber's salesman's order blank until those dozen are out in homes on duty and Bill is reaping the profit from them.

# Business Conditions

A Survey of Important Developments in the Electrical Market Including Data on Production, the Sales Outlook, Credits, Exports, the Metals and Other Conditions Affecting Cost, Supply and Demand

## Manufacture of Fixtures Gained 29 per Cent in Seven Years

The Department of Commerce on March 2 announced that, according to reports made to the Bureau of Census, the value of products of establishments engaged primarily in the manufacture of gas and electric fixtures amounted to $42,890,000 in 1921, as compared with $42,268,000 in 1919 and $28,740,000 in 1914. This shows an increase of 1 per cent from the year 1921 and an increase of 29 per cent for the seven-year period from 1914 to 1921.

This industry includes establishments manufacturing, as their products of chief value, gas fixtures, chandeliers, domes, burners, mantles, etc., and electric fixtures, holders, electroliers, brackets, portables, etc. Of the 308 establishments reporting products valued at $5,000 and over in 1921, 97 were located in New York, 41 in Pennsylvania, 31 in Illinois, 25 in Ohio, 24 in California, 13 in Wisconsin, 11 in New Jersey, 8 each in Michigan and Minnesota, 7 each in Connecticut and Washington, 6 in Missouri, 5 each in Maryland, Massachusetts and Tennessee, 3 each in Indiana, Iowa and Oregon, 1 each in Colorado, Kansas, Kentucky, Nebraska, Oklahoma and Rhode Island.

In December, the month of maximum employment, 10,680 wage earners were reported, and in August, the month of minimum employment, 8,787—the minimum representing 82 per cent of the maximum. The average number employed during the year was 9,419 as compared with 9,795 in 1919 and 10,913 in 1914.

The statistics for 1921, 1919, and 1914 are summarized in the table.

DATA ON MANUFACTURE OF FIXTURES—ELECTRIC AND GAS

| | 1921* | 1919* | 1914* |
|---|---|---|---|
| Number of establishments | 308 | 319 | 389 |
| Persons engaged | 11,735 | 12,379 | 13,649 |
| Proprietors and firm members | 203 | 221 | 320 |
| Salaried employees | 2,113 | 2,363 | 2,416 |
| Wage earners (average number) | 9,419 | 9,795 | 10,913 |
| Salaries and wages | $15,479,000 | $14,292,000 | $9,852,000 |
| Salaries | 4,419,000 | 4,490,000 | 3,348,000 |
| Wages | 11,060,000 | 9,802,000 | 6,504,000 |
| Paid for contract work | 41,000 | 65,000 | 67,000 |
| Cost of materials | 18,788,000 | 20,259,000 | 14,090,000 |
| Value of products | 42,890,000 | 42,268,000 | 28,740,000 |
| Value added by manufacture† | 24,102,000 | 22,009,000 | 14,650,000 |

*Statistics for establishments with products valued at less than $5,000 are not included in the figures for 1921. There were twenty-nine establishments of this class, reporting twenty-three wage earners and products valued at $77,000. For 1919, however, data for twenty-two establishments of this class, reporting sixteen wage earners and products valued at $59,000, and for 1914 data for seventy-one such establishments, with eighty-two wage earners and products to the value of $200,000, are included in all items with the exception of "number of establishments."

† Value of products less cost of materials.

## Denver Radio Equipment Sales Improving

Radio activities in Denver have been materially stimulated after the announcement that a new broadcasting station, backed by the leading radio jobbers and dealers in that city, will soon be put in operation. Although radio equipment has been moving well in the Denver territory for some time, a recent report indicates that improved broadcasting facilities are badly needed. Higher-priced sets are moving in good number in the Rocky Mountain territory. Crystal sets and cheap parts for home assembly are not so much in demand as they were last fall. Stocks, both jobbers' and dealers', are complete, and since the holidays there has been a marked standardization. Business in the radio departments of dry-goods and stores other than specialty or electrical shops has decreased.

## Active Demand for Wire in Many Types

Continued expansion of the electrical industry is throwing an immense amount of business upon wire manufacturers and jobbers, well ahead of the increased seasonal demand anticipated, as open weather permits the acceleration of construction work. All winter the sale of rubber-covered wire has been active, and the increased amount of building construction reported from many parts of the country has been a major factor in keeping the wire plants on full time. During the past few weeks a large amount of weatherproof wire has also been purchased, and in some sections the growth of interconnection and the insatiable demand of consumers for central-station service have resulted in heavy shipments from jobbers' stocks and from the manufacturing plants into the field. More life has appeared in the bare-wire market as a result of these interconnection programs, New England in particular having committed itself to a vigorous development in this field.

### CONSUMPTION INCREASING RAPIDLY

For months the reports of the business statisticians have marked substantial gains over contractual totals of a year ago, and both old and new building wiring jobs are demanding great quantities of wire. Campaigns for increased outlets are of some importance in this trade as well as the never-ending call of betterment jobs in industrial and mercantile establishments. Enormous increases in wire sales for telephone work are being noted, including the extension of toll cable facilities, some of which with auxiliary apparatus represent an investment of $35,000 per mile.

Advances in copper and cotton prices have lately been reflected in wire, and a good proportion of the business of the past month has been stimulated for early delivery by the anticipated stiffening of quotations as the prices of these basic commodities have risen. Notwithstanding the large volume of business being done, competition continues acute in the wire market. The delivery situation is aided somewhat by the production of wire in various localities, with the maintenance of supply by motor trucking in cases where railroad congestion is blockading freight movement. Considerable reliance is placed on boat

shipments in the Atlantic Coast market, and the outlook is much better along transportation lines than it was a few weeks ago. There seems little doubt that the year's business will be in most satisfactory volume, for the demand for wire for use in machinery, appliances, radio equipment and in miscellaneous applications is increasing, as are also the requirements of interior and outdoor service.

## The Metal Market

**Copper Advanced to 16.75 Cents—Sales Smaller—Discourage Reckless Buying—Export Demand Better**

The daily advance in copper prices continued until now 16.75 cents, delivered, has been reached, this figure being generally quoted by producers at the week end. Two or three producers have not yet come to that level. Sales have not been quite so great as last week, but this has been more because producers have been inclined to discourage reckless buying rather than due to any lack of inquiry. A particularly encouraging feature of the week has been a good export demand, which has made some producers care little about booking further domestic orders. Some of the export business has been for the Orient.

NEW YORK METAL MARKET PRICES

| | Feb. 27, 1923 Cents per Pound | Mar. 7, 1923 Cents per Pound |
|---|---|---|
| Copper | | |
| Electrolytic | 16.37½ | 16.75 |
| Lead, Am. S. & R. price | 8.00 | 8.10 |
| Antimony | 7.50 | 7.62½ |
| Nickel, ingot | 30.00 | 30.00 |
| Zinc, spot | 7.20 | 7.30 |
| Tin Straits | 43.12½ | 42.00 |
| Aluminum, 98 to 99 per cent | 24.00 | 24.00 |

## Meter Sales Are Gaining with Well-Maintained Deliveries

Improved demand for meters is a marked feature of the present manufacturing situation, and thus far, with the exception of some special equipment, deliveries are being well maintained. The expansion of the building industry and widespread development of house-wiring and outlet campaigns is being reflected in the production of representative manufacturers. Shipments are prompt on the more common lines and types. As a result of anticipating this business, conditions are reasonably good with respect to the supply of raw materials, and thus far the advancing prices noted in copper and cotton have not been reflected in quotations for meters.

In well-informed circles the opportunities for a larger development of industrial meter business are receiving some consideration, especially in connection with the rapid development of central-station service in industry and the possibilities of attaining higher manufacturing efficiency through more accurate studies of departmental operations and the derivation of more data as to energy consumption per unit of product in different portions of industrial establishments. Considerable "missionary work" will have to be done here before the business makes any great impression upon the trade.

### Chicago Trade Brisk

Increasing demands for electrical services in Chicago, coupled with new building construction, are improving the market for watt-hour meters. This situation also appears to be universal in the Middle Western territory radiating from Chicago. With the increase of 73,321 new customers on the Commonwealth Edison Company lines during the year, each requiring a new meter, some indication can be given as to the number of meters needed in this territory. Jobbers' supplies are in good condition and prices remain firm. The Public Service Company of northern Illinois had a customer increase during 1922 of 20,938.

# The Week in Trade

**Prices When Quoted Are Those Reported at the Opening of Business on Monday of This Week for Points West of the Mississippi River and on Tuesday for All Eastern Points**

STEADY progress is reported for the electrical market during the week just ended. Conduit stocks in the New York and Massachusetts territories are improving despite poor transportation caused by snow and rain in the interior states. An active call for meters, poles and wire by the utilities is noted. Lamps are said to be selling in greater volume. Appliance sales are slower than two weeks ago.

**Boston** General business is gaining momentum and the electrical industry is intensely active. Buying for stock is still being done conservatively, although the hardening of prices in basic commodities has stimulated orders sharply for the time being. The arrival of delayed shipments of conduit has relieved the scarcity in this line to a considerable extent. Shortages still exist in radio tubes, and poles are still scarce on account of bad road conditions in the interior. Business is greatly hampered by delays in mail service, notably between New York and Boston. Labor is very widely employed. The textile and leather industries are extremely busy and retail trade is developing steadily. Building contracts in New England totaled $2,933,700 for the week ended Feb. 27, against $1,565,800 for a year ago.

**New York** Business in the electrical market continues at a steady gait with some falling off in the demand for appliances and radio. Commodities which have taken on added interest during the last few days are meters, motors and lamps. Conduit stocks are reported to be slightly improved with rather higher prices noticed in the wire lines. Construction projects are progressing fairly well, and the demand for all electrical materials entering into new buildings is expected to pick up to the highest strength of last year at from two to three months earlier. Collections are reported to be only fair.

**Baltimore** The transportation situation has hindered deliveries along certain lines, causing a falling off in stock for some of the jobbers, although not to any detriment to business, owing to the fact that most jobbers are well stocked in all lines. There has been a more steady demand for motors, especially in the larger sizes. There is an expected activity in wire due to the increase in the price of copper. The exceedingly warm spell which is breaking all heat records for this period in the year for this section has completely demoralized the market for all heating apparatus. Commercial fixtures and lamps have been holding their own, and there is a fair demand for cable.

**Atlanta** Electrical jobbers report very satisfactory sales in the 5-amp. and 10-amp. two-wire and three-wire meters, small residential and commercial construction having acted as quite a stimulus to sales. Jobbers' stocks are in good shape, with the exception of the large and high-tension types. Wire continues to move briskly, despite continued price advances, and local stocks of the more popular sizes are somewhat depleted. Shipments from factory on the larger sizes are becoming longer. Electric range sales are satisfactory, and one jobber expressed the opinion that his sales this year will be at least 100 per cent in excess of those last year. Stocks are satisfactory and prices generally firm.

**Pittsburgh** The general tendency is for increased business in all lines. There was a specially good business report during the week on electrical appliances. One jobber reported as having received an order for ranges for a large apartment dwelling now being constructed. Increased business was reported by the jobbers from the industrials, this being of greater volume than ever before. It is quite noticeable that these orders are for new material rather than for piece parts as in the past. During the week new agreements were signed by practically all building crafts in this territory, which means that labor troubles will be averted during 1923 and a portion of 1924. Central stations are showing a marked activity in the way of taking over new territory.

# Demand, Supply and Price Trend of Nineteen Commodities as Sold in Sixteen Cities

Explanation:
Demand: Steady, Slow or Active
Supply: Normal, Low or High
Price Trend: Firm, Decreasing or Increasing

Next Week
Reports will include
Conduit Boxes, Signal Apparatus
and Rectifiers

| | Wire | Armored Cable | Conduit | Transformers | Poles | Pole Line Hardware | Porcelain | High Tension Equipment | Fuses | Meters | Switches | Wiring Devices | Lamps | Commercial Fixtures | Motors | Radio | Instruments | Electric Ranges | Hollow Ware |

## Cleveland

Dealers as well as manufacturers and jobbers enjoyed a very satisfactory week. Improvement in industrial equipment is evident. Wire, conduit and copper stocks are extremely low and demand constantly increasing. Prices of these commodities are advancing rapidly in consequence, while deliveries are hampered by poor transportation. Poles, porcelain and hardware are recovering gradually but with firm prices. Appliance sales are in greater volume, with active interest in heaters and ranges, due to the gas controversy and cooler weather. Radio equipment is in fair demand, and the tube shortage has been relieved somewhat. Meters are in better demand and central-station business is most promising. Building operations are handicapped slightly by labor difficulties, but plans are under way to assure an active spring. Fixtures are moving well and collections are in good shape.

## Chicago

Electrical business, according to jobbers and manufacturers, is steadily forging ahead. Building construction requires an increasing amount of wire and wiring materials, although prices on these commodities are gradually strengthening. Demand on commercial fixtures is also active. The call for motors is up to the previous sales rate, but shipments from manufacturers are slowing up. The porcelain market is a little irregular, since manufacturers are somewhat pressed for raw material.

## St. Paul-Minneapolis

All steel products are on the rise. Stocks are getting low on all kinds of wire. Demand from the country is still active for all lines. Retail business is dragging. Appliances are slow, but wiring is fairly active. Jobbers expect a lull for about three weeks for all lines.

## St. Louis

An increase of approximately 40 per cent is reported in the sale of electrical supplies during the past month over the same period a year ago. This is attibuted to the general improvement in business, almost uninterrupted building operations during the winter and heavy buying by the public utility companies.

Orders for automobile equipment have also aided in swelling the sales for this month. There is an excellent demand for small motors for household appliances, and more than the usual seasonal volume of contract work for wiring is reported. Electrical equipment for mining work and for the oil fields is moving well. The consumption of electrical energy for industrial purposes shows an increase of almost 70 per cent over the same month last year.

**Denver** Cold weather is holding back outside construction. Improved broadcasting programs have stimulated both interest and trade in radio. Electric commercial vehicles are again developing interest in this territory after a decade of inactivity. Steel mills are working at capacity and coal shipments are moving easily. Business is good and the electrical industry is profiting, but not in the degree it should if conditions through the territory were more stabilized.

**New Orleans** The feature of the market is the continued and steady rise in the price in wire, the largest item in electrical installation. Wire is now about 25 per cent higher than it was last year, and the copper, rubber and cotton markets indicate further increases. The market for ranges is increasing.

**Salt Lake City** The real-estate market is showing improvement, particularly in the larger towns and cities. Homes are in fair demand, and the 1923 cottage construction program promises to be on a par with that of 1922. The month of March opened with bonds showing strength and mining stocks in a much improved condition. A more pretentious live-stock show will be staged in April than has been held in several years past, a fact indicating marked improvement in that important Intermountain industry.

**San Francisco** Building is brisk, averaging about a 15 per cent increase over last year. Retail business is good, department stores especially reporting excellent business as compared with 1920. The recent San Francisco automobile show gave good indication of increasing buying power in its attendance and immediate sales. Labor conditions continue excellent, and non-employment is virtually confined to unskilled laborers. Conduit demand is active after a 5 per cent increase. Stocks are far below normal. Construction demand is steady. Power company crews report progress in apartment-house sales. The popularity of white-enameled ranges has necessitated local stocks of several makes. Percolator sets, in urn patterns, and waffle irons are especially popular. Silver-finish sets are increasing slightly in demand, but the real call is for nickel sets listing from $30 to $40. Collections are improving.

**Portland-Seattle** Business conditions continue to hold up in good shape. The value of building permits for the first two months of this year is materially in excess of that of a year ago, and the same condition applies to electrical permits. Conduit stocks are still in a precarious condition with a sustained active demand, slow deliveries and short stocks. Manufacturers are no longer quoting prices in advance and jobbers' orders are placed subject to price at time of shipment. Another advance in the base price of copper is reported for the past week. Weatherproof wire followed the rise, but rubber-covered has not yet been affected.

# Activities of the Trade

Devoted to News of the
Manufacturer, Jobber, Agent, Contractor and Dealer, Including Important Orders and Contracts for Apparatus and Equipment

## Gain in Allis-Chalmers Orders

Orders on the books of the Allis-Chalmers Company, Milwaukee, on Feb. 1 amounted to $9,000,000, compared with $8,400,000 on Jan. 1. Officials of the company estimated that the total on March 1 would be at least $9,500,000. The lead in incoming orders has been taken by the electrical cement machinery and turbine departments.

## Westinghouse Electric Rents Half of Proposed Skyscraper

The Westinghouse Electric & Manufacturing Company last week leased for a period of ten years twelve floors in the new twenty-three story bank and office building to be erected at 150 Broadway, New York City, by the 150 Broadway Corporation. The building will be known as the Westinghouse Building. The space leased by the Westinghouse company comprises between 90,000 sq.ft. and 95,000 sq.ft., and the amount of money involved in the lease is in excess of $3,000,000.

The Westinghouse lease is for all the floor space from the twelfth floor to the twenty-third floor, inclusive. Co-tenants with the Westinghouse Electric & Manufacturing Company will be the Westinghouse International Company, the Westinghouse Lamp Company and the Westinghouse Air Brake Company. It is expected that considerably more available office space in the building will be leased to companies allied with the Westinghouse company's business. The offices of the Westinghouse Electric & Manufacturing Company are now at 165 Broadway.

## Electric Power Equipment Firm Arranges Agency in Seattle

The Electric Power Equipment Corporation, Fifteenth and Wood Streets, Philadelphia, announces that it has arranged an agency in Seattle, Wash., with Eicher & Bragg, 2107 L. C. Smith Building. This agency will cover the states of Washington and Oregon. This agency is handling, in addition to the line made by the Electric Power Equipment Corporation, equipment of the Kelman Electric & Manufacturing Company, Pittsburgh Transformer Company, Pittsburgh Electric Furnace Corporation, Jewell Electric Instrument Company and the Stromberg lines.

## To Manufacture and Repair Transformers in Newark

D. J. Norton, formerly of the General Electric Company's Pittsfield works and for the past seventeen years superintendent of the American Transformer Company, Newark, N. J., has opened a manufacturing plant at 71 Hamilton Street, Newark, specializing in manufacturing and repairing of transformers. Special attention will be given to engineers having their own designs, and estimates will be furnished on request.

## Rome Wire Plans Addition

The Rome Wire Company, Rome, N. Y., manufacturer of electrical wires and cables, will build a one-story addition to its branch plant on Clyde Avenue, Buffalo, to be 33 ft. x 300 ft. and estimated to cost about $42,000. It will be used for general increase in production. The contract for the work has been awarded to the John W. Cowper Company, Fidelity Building, Buffalo.

## Apex Representatives Meet

Fifty Southern representatives of the Apex Electrical Distributing Company, including state and branch managers and salesmen of the company, attended the annual Southern district sales convention in Atlanta on March 3. The principal speakers were R. J. Strittmatter, sales manager of the company, Cleveland, and R. H. Short, Southern district sales manager, Atlanta.

## Buffalo Fuse Corporation Plans Sales Expansion

Rapid sales expansion is planned by the Buffalo Fuse Corporation, 72 Main Street, Buffalo, which a year ago took over the manufacturing of the renewable electric fuse formerly made by the Pierce Fuse Corporation. The company has just amended its incorporation to provide for $50,000 preferred stock in addition to its 2,000 shares of common. The new board follows: Robert F.

Bickford, president; W. S. Harrison, vice-president; John G. Clemens, secretary, and Lambert G. Smith and Harvey B. Harrison, additional directors.

## Northwest Electric Changes Name

The Independent Electric Company is the new name of the Northwest Electric Apparatus Company, Security Building, Minneapolis. The reason for this change was that the company was sometimes confused with other companies and also that it was representing independent manufacturers in the capacity of manufacturers' agent.

## P. A. Geier Announces Spring Housecleaning Sales Contest

A spring housecleaning sales contest, which will run from April 2 to June 2, has just been announced by the P. A. Geier Company, Cleveland, manufacturer of the "Royal" cleaner. This contest is open to retail salesmen, cash or merchandise prizes being awarded not only to the leaders, but to all who qualify with a reasonable number of sales.

Previous contests conducted by this manufacturer have proved very successful in stimulating selling activity during seasons which are normally considered dull. The present competition, held during the period of heaviest demand, is expected to give exceptional results.

## To Handle Anaconda Sales

A new organization, to be known as the Metals Sales Corporation, will be formed to handle the sales of copper of the Anaconda Copper Mining Company. This business heretofore has been handled by the United States Metals Selling Company, which in the future will handle the sales of lead, zinc and other metals other than copper.

The new organization will take over all liabilities of the United States Metals Selling Company involving the sales of copper. It is expected to be the second largest organization of its kind in existence, and if later it should handle the sales of copper produced by the Chile Copper Company, now controlled by Anaconda, it is expected to hold first rank in the metal-selling business.

## Uehling Instrument Appoints Agents in Japan and China

Mitsui & Company have just been appointed exclusive representatives in Japan and China for Uehling $CO_2$ recording equipment and other Uehling power-plant instruments and gages. The head office of Mitsui & Company is in Tokio, and the New York branch office of the company is located at 65 Broadway.

The main office and factory of the Uehling Instrument Company is in Paterson, N. J. Many Uehling installations have been made in Japan and China without the aid of local representatives, but it is believed that with the co-operation of the engineering department of Mitsui & Company the Japanese and Chinese Uehling customers will be served to advantage.

## Benjamin Electric Appointments

The Benjamin Electric Manufacturing Company, Baltimore, has announced that Merritt L. Tice, district sales representative, will soon take on added territory in North and South Carolina, Georgia, Florida and parts of Tennessee and Alabama. Additional men will be put into the district and the territory more intensively served.

Thomas F. McDonough is now in charge of the Northwest territory of the Benjamin Electric Manufacturing Company, consisting of Montana, Idaho, Washington and Oregon, with headquarters in the L. C. Smith Building, Seattle. The company also announces that Carl O. Martin, formerly in charge of the Northwest sales territory, has been transferred to a larger field, with headquarters in San Francisco. He will serve in that city as assistant to Miles S. Steel, Pacific Coast manager.

---

**The Century Electric Company**, manufacturer of single and polyphase motors, St. Louis, has opened an office at 603 Queen and Crescent Building, New Orleans, where a complete stock of motors will be carried.

**The Union Electric Manufacturing Company**, South Bend, Ind., of which Fred. A. Bryan is president, has recently been absorbed by the Indiana & Michigan Electric Company by the purchase of stock by the latter company. No change in management will occur, it is said. Hugh McVicker will continue as manager and Joseph Black as superintendent.

**The Sunlight Lamp Company**, which has been operating in Warren, Ohio, under the name of the Sunlight Electric Company, has moved to Newton Falls, Ohio, having acquired the building formerly occupied by the Newton Manufacturing Company.

**The Weldon Manufacturing Company**, Detroit, electrical specialties, will establish a plant at Grand Rapids, having purchased a site at Russell Avenue and the Père Marquette Railroad. It is announced that contracts have been let for a factory, 50 ft. x 125 ft.

**The Gibb Instrument Company**, Bay City, Mich., manufacturer of welding equipment, has increased its authorized capital stock from $75,000 to $175,000. Of the increase, $40,000 has been sold at par value to provide increased manufacturing facilities and to take care of increasing business.

**The Cornell-Mathews Company**, sales engineers, Christ Building, Orlando, Fla., announces the closing of a contract with the Orlando Utilities Commission for all-steel switching and distribution towers equipped with air brakes, switching apparatus and choke coils. The structures are 50 ft. long and 40 ft. high and contain 48,000 lb. of structural steel. The entire output of the new generating station for Orlando will be carried underground in cable and distributed from the switching towers described above. The Cornell-Mathews firm is district agent for the Delta Star Electric Company, Chicago.

**The American Electrical Supply Company**, 953 Washington Boulevard, Chicago, on March 1 moved into a new building at 117 South Morgan Street. C. E. Browne is president of the company.

**The Art Craft Fixture Company**, 85 Academy Street, Newark, N. J., manufacturer of lighting fixtures, has acquired a factory at Adams, Malvern and Delancey Streets for a new plant. The present works will be removed to this location and additional machinery installed, according to officials of the company.

**The E. H. Freeman Electric Company**, Meade and Prince Streets, Trenton, N. J., is arranging for the installation of equipment and operation of its three-story addition, 35 ft. x 164 ft., now being completed for the manufacture of electrical equipment.

**The Holland Maid Company**, Holland, Mich., has been organized with a capital of $400,000 to take over the plant of the Holland Manufacturing Company, manufacturer of electric washing machines and clocks.

**The Am-Plus Storage Battery Company**, formerly at 741 Van Buren Street, Chicago, has leased the third floor, 100 ft. x 100 ft., of the building at 449 West Superior Street.

**Carman & Fryer**, Indianapolis, operating an electrical contracting business, have acquired the electrical repair department of the Vonnegut Machine Company, with local works and will operate it in the near future. The works will be extended and additional equipment installed, according to officials of the firm.

**James Seffel & Company**, Springfield, Ohio, manufacturers of turbines, water-wheels, etc., have announced the removal of their Boston office from 161 Devonshire Street to the Little Building, 80 Boylston Street, Boston.

**Hall Brothers Cedar Company**, formerly of Jacksonville, Tex., has recently moved to Cœur d'Alene, Idaho, and will engage in the manufacture and wholesaling of western red cedar posts, poles and piling.

**The Wise-McClung Manufacturing Company**, New Philadelphia, Ohio, has appointed G. B. Gaiennie as general manager of the Sunshine Sales Company, with offices in Cleveland, Ohio.

**Commercial Truck Company.**—F. F. Espenschied, who represents the Commercial Truck Company, makers of the C-T Electric Truck, in the Pittsburgh territory, has added the local account of the Electric Machinery Manufacturing Company, makers of synchronous motors, alternators and motor-generator sets.

## Foreign Trade Notes

FUNDS SECURED TO COMPLETE THE HYDRO-ELECTRIC PLANT ON TEIGIBSCH RIVER, AUSTRIA. — Arrangements have been made by the Steirische Weag Aktien Gesellschaft to secure a loan of 5,000,000 francs from a Swiss banking group, which will enable it to complete the hydro-electric station now in course of construction on the Teigibsch River and to begin work on other hydro-electric projects in its program.

A MODEL ELECTRICAL FARM IN SWEDEN. — To encourage the use of electricity in agriculture, a model electrical farm, according to *Commerce Reports*, is being established near Stockholm, Sweden, and demonstrations of electrically operated plows, harrows, harvesters, threshing machines, churns, separators, etc., will be given.

MANUFACTURE OF INCANDESCENT LAMPS IN NORWAY.—The rights of the Osram patent (German) for Norway, *Commerce Reports* states, have been acquired by a new company. Existing plants have been modernized so that they are now capable of producing 5,000 lamps daily, which is sufficient to supply the Norwegian trade. The factory is under the supervision of workers brought from Germany and the lamps are said to be exact replicas of the German product.

INVESTIGATIONS OF WATER-POWER PROJECTS IN BELGIAN CONGO.—Investigations are now being made by hydro-electric engineers, according to *Commerce Reports*, of the possibilities of two large water-power projects in the Katanga district of the Belgian Congo. One is a 60,000-70,000-hp. project on the Lualaba River, and the other a 50,000-hp. development on the Lufira River. The latter includes a mass-concrete intake dam and an earthen reservoir dam 17 m. high. The schemes are as yet only in the project stage.

ELECTRIC SIGNS IN LILLE, FRANCE. —Electric advertising signs, unknown in 1921 and even late in 1922, have appeared in various parts of the business centers of Lille, France, according to a report of Vice-Consul J. G. Finley to the Department of Commerce. The development of electric sign advertising is becoming noticeable in France and should lead to a market for American waterproof sockets and sign appliances in all important commercial and industrial centers of that country.

## Foreign Trade Opportunities

TELEPHONE INSTALLATION IN COLOMBIA.—A new telephone system has been installed in Barranquilla, Colombia. A long-distance line to Cartagena and a new system in Cali is proposed. The system in Barranquilla was installed by an American company.

ELECTRIC PLANT TO BE INSTALLED AT ITARSI, INDIA.—The Itarsi (India) Industrial Corporation, according to *Commerce Reports*, will require an electric plant to supply electricity to the town of Itarsi and to furnish power for driving saws.

CONCESSION ASKED TO INSTALL A TELEPHONE SYSTEM IN BRAZIL. — Application has been made to the Secretary of Public Works of the State of Rio Grande do Sul by Argentine interests, *Commerce Reports* states, for a concession to install a telephone system in the city of Uruguayana and join it with the systems in the municipalities of Quarahy, Alegrete and Livramento.

NEW TELEPHONE SYSTEM PROPOSED FOR REVAL, ESTHONIA.—The telephone system in Reval, Esthonia, is to be enlarged to provide for 2,500 subscribers. The present system is of the old Russian type, and the Post Administration proposes to install two automatic stations, each to have a capacity of 500 telephones. The plans provide for 10,000 telephones eventually. An item of 35,800,000 marks (approximately $105,000 at the present rate of exchange) is included in the national budget for 1923, now before the State Assembly, for such construction.

ELECTRIC PROJECTS IN SPAIN. — Plans are being prepared by the Co-operative de Flúido Electrico of Barcelona for supplying electricity in the Barcelona district. The company proposes to utilize the falls on the River Cadi and coal from its own mines. Several Asturian coal companies, it is announced on the Bourse, have formed a group with a capital of 4,550,000 pesetas, of which 3,100,000 is contributed by the Duro-Fêlguera concern, to generate electricity by utilizing coal of an inferior quality. The initial capacity of the project will be 5,100 kw., to be supplied by the Duro-Felguera Company.

ELECTRICALLY DRIVEN PUMPING EQUIPMENT FOR BUENOS AIRES. — Tenders will be received by the Department of Sanitary Works, Buenos Aires, Argentina, until April 26 for nineteen groups of vertical centrifugal pumps with electric motors and spare parts.

## New Apparatus and Publications

ARMATURE AND FIELD TESTERS.—The Century Electrical Company, 100 Randall Avenue, Syracuse, N. Y., is distributing a folder describing the "Century" armature tester and also a booklet covering the "Century" field tester for testing fields and armatures.

MOVING SIGN. — The American Sign Company, Kalamazoo, Mich., has brought out a new moving sign, known as the "Roto-Sign."

ELECTRIC CLOTHES DRIER.—The Airo Electric Appliance Company, Columbia Building, Pittsburgh, is manufacturing the "Airo" electric clothes drier.

REEL FOR PORTABLE ELECTRIC TOOLS.—Forbes & Myers, 172 Union Street, Worcester, Mass., have placed on the market a reel for use with portable electric tools.

ANGLE AND STRAIGHT CONNECTORS.—The Sprague Electric Works of General Electric Company, 527 West Thirty-fourth Street, New York City, have designed a new duplex Y-shaped connector made in both the straight and 90-degree-angle types.

STEAM-POWER PLANTS. — "Steam Power" is the title of a booklet distributed by the J. G. White Engineering Corporation, 43 Exchange Place, New York City, which describes and illustrates some of the more important steam-power plants which have been built by the corporation.

INDUCTION FURNACE.—Bulletin No. 2 issued by the Ajax Electhrothermic Corporation, 636 East State Street, Trenton, N. J., describes the "Ajax-Northrup" high-frequency induction furnace.

SURGE ARRESTERS.—Bulletin No. 4-A distributed by the Electric Service Company, Marietta, Ga., covers the "Bennett" surge arresters and disk gaps.

BATTERY CHARGER. — A new small battery-charging set has been developed by the Ohio Electric & Controller Company, 5900 Maurice Avenue, Cleveland.

PORTABLE WELDING GENERATORS. —The Alexander Milburn Company, 1416-1428 West Baltimore Street, Baltimore, has recently placed on the market a portable acetylene welding generator, designed to obviate the use of high-pressure cylinders.

BELL-RINGING TRANSFORMER. — A new bell-ringing transformer has been developed by the Killark Electric Manufacturing Company, St. Louis.

SINGLE-PHASE MOTORS.—Bulletin No. 131 issued by the Wagner Electric Corporation, St. Louis, gives instructions for ordering and adjusting repair parts for the "Wagner" single-phase repulsion induction motors.

COKE PLANT MACHINERY. — Leaflet 1,867 issued by the Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., describes electrical equipment for coke-plant machinery.

## New Incorporations

THE BURKE POWER COMPANY, Morgantown, N. C., has been incorporated with a capital stock of $1,000,000 by A. M. Kistler and others to develop water power in that section.

THE ILLINOIS POWER & LIGHT CORPORATION, 122 South Michigan Avenue, Chicago, has been incorporated with a capital stock of $1,000 by A. C. Winters, H. W. Snell and M. G. Grover.

THE MANUFACTURERS' POWER CORPORATION, Rome, N. Y., has been incorporated by H. T. Dyett, H. D. Wolfe and E. L. Spriggs. The company is capitalized at $50,000 and proposes to generate electricity. M. J. Larkin, Rome, is attorney.

# Construction News

**Projects, Plans, Bids and Contracts, Contemplated or Under Way**

## New England States

BOSTON, MASS. — The Edison Electric Illuminating Company will commence work at once on the construction of a power plant on Summer Street, to cost about $500,000.

BOSTON, MASS. — The Gillette Safety Razor Company, 41 West First Street, will install electric power equipment in its proposed factory addition on Dorchester Avenue, to cost about $200,000. Charles T. Main, 49 Federal Street, is architect and engineer.

NORTH ABINGTON, MASS.—The Electric Light & Power Company of Abington and Rockland is arranging for a stock issue of $136,000, part of the proceeds to be used for extensions, etc.

FAIR HAVEN, CONN.—The Ward Baking Company will build a power house in connection with a proposed local baking plant, to cost about $250,000. C. B. Comstock, 110 West Fortieth Street, New York City, is architect and engineer.

LYME, CONN.—The Eastern Connecticut Power Company, Norwich, is negotiating for the purchase of the property of the Lyme Electric Company and a controlling interest in the Danielson & Plainfield Gas & Electric Company.

NEW HAVEN, CONN.—The Connecticut Power Company will soon begin work on an addition to its power house on Grand Avenue, to cost about $25,000, exclusive of machinery.

## Middle Atlantic States

LOCKPORT, N. Y.—The City Council has awarded the Lockport Light, Heat & Power Company a contract for street lighting for a period of three years, to furnish a minimum of 705 lamps. In addition the company was given a contract to install seventy-two new lamps on Main Street in the business section.

MALONE, N. Y. — Seventy additional 400-cp. single-lamp standards will be erected on five residential streets this year. The Malone Light & Power Company furnishes the street-lighting service. S. G. Hunter is operating manager.

MASSENA, N. Y. — The plant of the Beakes Dairy Company, including its power house, was damaged by fire recently, causing a loss of about $100,000.

NEW YORK, N. Y.—The New York Edison Company will build a three-story substation at 127 East 120th Street, to cost $85,000.

PENN YAN, N. Y.—The Yates Electric Light & Power Company has applied to the Public Service Commission for permission to erect a new generating station at Cascade Mill, to cost about $500,000.

WATERTOWN, N. Y.—Bonds to the amount of $415,000 have been voted to develop the water power at Delano Falls.

NEWARK, N. J. — The Department of Public Affairs, City Hall, contemplates the erection of an addition to the power station at the city alms house.

NEWARK, N. J. — The Public Service Electric Company will reconstruct a portion of its transmission system in different parts of the state, changing from two-phase to three-phase system.

PHILLIPSBURG, N. J.—The New Jersey Power Corporation has been organized by W. S. Barstow & Company, 50 Pine Street, New York, with a capital of 25,000 shares of stock, no par value, to construct and operate a power plant and system in this section. It will be operated in conjunction with the New Jersey Power & Light Company, Dover.

ASHLEY, PA.—The installation of an ornamental lighting system on Main Street is under consideration by the Borough Council.

FREEBURG, PA.—The Freeburg Power & Light Company, recently organized, contemplates the installation of a local distributing system. A transmission line will be erected. C. M. Walter, Allentown, is treasurer.

HAZLETON, PA.—The Jeddo Highland Coal Company is planning to build a power house at its No. 2 Highland Colliery, to replace the one recently destroyed by fire.

HOLTWOOD, PA. — The Pennsylvania Water & Power Company has issued $450,000 in bonds, the proceeds to be used for extensions to its hydro-electric power plant, comprising two units, each 19,000 hp., on the Susquehanna River.

PHILADELPHIA, PA. — Bids will be received by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., until March 20 for 5,000 ft. electric wire for use at the local navy yard. (Schedule 584.)

PITTSBURGH, PA.—The Press Publishing Company, 228 Oliver Avenue, will install electric motors and other power equipment in its proposed newspaper-publishing plant at Seventh Avenue and Bigelow Boulevard, to cost about $800,000.

YORK HAVEN, PA.—The York Haven Power Company has acquired property on the Susquehanna River for extensions to its power dam and generating station.

BALTIMORE, MD. — The Consolidated Gas, Electric Light & Power Company is arranging funds to the amount of $6,500,000 for extensions and improvements during the present year.

CHARLESTON, W. VA.—The Virginian Power Company is considering the construction of a hydro-electric plant on the New River, near Hinton, to cost about $300,000.

BRISTOL, VA.—The Big Jack Overall Company, Inc., Lee and Water Streets, contemplates extensions to its power house.

NORFOLK, VA. — The Pender Grocery Company will install motors and other electric power equipment at its proposed baking plant at Twenty-fifth Street and Fawn Avenue, to cost about $125,000.

SUFFOLK, VA. — The America Brick Corporation will build a substation in connection with its proposed new brick-manufacturing plant.

WASHINGTON, D. C.—Bids will be received by the Chief Signal Officer, United States Army, until March 16 for 12,000 dry batteries. (Circular PR 14,085-1 CP.)

## North Central States

ALBION, MICH. — P. E. Ganson, local manager of the Consumers' Power Company, has submitted a proposal to the City Council offering to install a new street-lighting system, to cost about $26,000.

BAY CITY, MICH.—Bids will be received at the office of the W. H. Reid, city manager, City Hall, until March 12 for furnishing and installing electric lighting systems and power wiring in pumping station and filtration plant. Bids will also be received at the same time for one 5,000,000-gal.-per-minute motor-driven centrifugal pump, complete with connecting piping, and for two 10,000,000-gal.-per-minute steam turbo-centrifugal pumps with condenser and auxiliaries. The Frazier-Ellms-Sheal Company, B. F. Keith Building, Cleveland, is engineer.

DETROIT, MICH.—Roehm & Davison, Mack Avenue, will install electric power equipment in the proposed addition at their iron and steel works, Mack and Beaufaite Avenues, to cost about $100,000.

AKRON, OHIO.—Electric lamps will be placed on the High Level Bridge, the expense to be paid by the city.

CLEVELAND, OHIO.—Bids will be received at the office of the Commissioner of Purchases and Supplies, City Hall, until March 16 for one 600-hp. steam turbine for the Fairmount pumping station.

CLEVELAND, OHIO. — The Teachout Company, Prospect Avenue, manufacturer of sash, doors, etc., will install motors and other electric equipment in the proposed addition to its plant, to cost about $250,000.

WASHINGTON C. H., OHIO.—Plans are being prepared by the Washington Gas & Electric Company for extensions to its plant, including the installation of new equipment.

DECATUR, IND.—Extensions and improvements will be made in the municipal light and power plant and waterworks, including the installation of additional machinery, to cost about $40,000.

FORT WAYNE, IND. — The Indiana Service Corporation has issued $1,000,000 in bonds, part of the proceeds to be used for extensions and improvements.

INDIANAPOLIS, IND. — The Burnet-Birford Lumber Company, 1401 West Thirtieth Street, contemplates extensions to its power plant, including the installation of boilers, etc.

CHICAGO, ILL.—The Marquette Cement Company, 140 South Dearborn Street, will install electric power equipment in a new building, to be erected at Elston and Redfield Streets, to cost about $260,000.

CHICAGO, ILL.—The Pullman Company, 79 East Adams Street, will install electric power equipment in its car shops, to be erected at Cottage Grove Avenue and 103d Street, to cost about $150,000.

SPRINGFIELD, ILL.—The installation of an ornamental lighting system on Noble Avenue from South Grand Avenue to Laurel Street is under consideration by the City Council.

AMERY, WIS.—The Wisconsin Hydro-Electric Company has acquired the electric light and power plants in Poskin, Hillsdale and Dallas. The company will extend its lines to these communities and establish a twenty-four-hour service.

FOND DU LAC, WIS.—The City Council has authorized the installation of a new fire-alarm system, to cost $7,000.

MANITOWOC, WIS.—The City Council has authorized the Board of Public Works to secure estimates for extensions and remodeling the municipal electric light and power plant, to include the installation of the following equipment: One 2,000-kw. turbine, to replace a 300-kw. unit; two 4,000-hp. boilers; one 2,000-hp. feed-water heater, duplex pump, mechanical stokers, complete switchboard equipment and auxiliaries.

MARKESAN, WIS. — Plans are being prepared by the River View Canning Company for the construction of a canning factory and power house, to cost about $50,000.

NEENAH, WIS.—Preliminary plans are being prepared by Cahill & Douglas, engineers, 217 West Water Street, Milwaukee, for a power house, 60 ft. x 160 ft., for the Valley Paper Mills.

OWEN, WIS.—The Wisconsin-Minnesota Light & Power Company is planning to erect a high-tension transmission line from Owen to Curtiss.

PESHTIGO, WIS. — The Northeastern Power Company, a subsidiary of the Wisconsin Public Service Corporation, Green Bay, is planning to erect a new transmission line between Peshtigo and the Air Line Road.

WAUKESHA, WIS.—The installation of an ornamental lighting system in the business district is under consideration by the City Council.

BRAINERD, MINN.—Bids, it is reported, will soon be asked for a 200-hp. engine and generator for the waterworks pumping station. L. P. Wolff, Guardian Life Building, St. Paul, is engineer.

ST. PAUL, MINN. — The Ford Motor Company, Detroit, Mich., has been granted permission by the Federal Power Commission to construct a hydro-electric power plant at the High Dam, Mississippi River, to be used in connection with a proposed local automobile and tractor plant, to cost about $2,000,000.

DAVENPORT, IOWA.—The substitution of a single-unit street lamp for the present five-lamp electroliers is under consideration by the light committee of the City Council.

ROCHESTER, IOWA.—Plans have been prepared by the Iowa Railway & Light Company, Cedar Rapids, for the construction of a hydro-electric plant and dam on Cedar Rapids at Rochester. Three plans are under consideration: (1) a five-unit plant, 22-ft. head, to cost $1,317,000; (2) an eight-unit plant, 22-ft. head, to cost $1,551,000; (3) an eight-unit plant, 27-ft. head, to cost $1,963,000.

MARTHASVILLE, MO. — The Marthasville Electric Light & Power Company, recently organized, is preparing plans for a electric light and power system.

KANORADO, KAN. — The Council has awarded a contract to the Goodland (Kan.) Light & Power Company to furnish electricity in Kanorado. Bonds to the amount of $25,000 were recently voted to erect a transmission line and distributing system.

## Southern States

CHARLOTTE, N. C. — An electrically operated pumping plant will be installed in the proposed municipal filtration plant and waterworks, to cost about $300,000.

COCOA, FLA.—The plant of the Cocoa Ice & Light Company has been acquired by the Southern Utilities Company, Palatka. Improvements, it is said, will be made to the system.

MARIANNA, FLA.—The Marianna Light & Power Company has started work on the construction of a power plant on the Chipola River in Marianna. G. M. Thomas is interested in the company.

LIVINGSTON, TENN.—The Cumberland Power Company, which recently acquired the local plant, plans to erect a transmission line to Rock Island, a distance of 25 miles, to connect with its water-power plant.

ALBERTVILLE, ALA. — The municipal electric plant and waterworks system has been acquired by the Alabama Water Company, which will make improvements to same.

CITRONELLE, ALA. — The Citronelle Light & Power Company contemplates building an ice-manufacturing and cold-storage plant.

RIVER FALLS, ALA.—The Public Service Commission has granted the River Falls Power Company permission to build a hydro-electric plant on the Conecuh River, near River Falls.

CORINTH, MISS.—The City Council contemplates an expenditure of about $200,000 for municipal improvements, including electric light plant, waterworks and street work.

POPLARVILLE, MISS.—The Love Lumber Company plans to rebuild its power house and lumber mill, recently destroyed by fire, causing a loss of about $100,000.

RAYNE, LA.—Bids will be received by the Mayor and the Council of Rayne at the office of the city clerk until March 20 for improvements to the municipal electric light plant and waterworks system, including the construction of power house, two 200-hp. or one 300-hp. oil-engine generator unit, one three-panel or one two-panel switchboard, one deep well, one 750-gal.-per-minute deep-well centrifugal pump and motor, one air lift system for pump, cast-iron pipe, etc. The J. B. McCrary Company is engineer.

MUSKOGEE, OKLA. — The Oklahoma General Power Company is planning to erect an addition to its local steam-driven plant, increasing the output by 20,000 hp., to cost about $1,000,000.

SAND SPRINGS, OKLA.—Electric power equipment will be installed in the new plant of the Sand Springs Cotton Mill Corporation, to cost about $115,000.

WYNNEWOOD, OKLA.—The Texas Pacific Refining Company will install electric power equipment at its proposed local oil refinery.

FORT WORTH, TEX.—The installation of a street-lighting system in the Rosen Heights district is under consideration.

HOWE, TEX.—Plans for the proposed new waterworks system call for the installation of electrically operated pumping machinery.

PANHANDLE, TEX.—Plans have been completed for the construction of a transmission line for local light and power service.

STAMFORD, TEX. — The West Texas Utilities Company has completed plans for the construction of a local power plant for auxiliary service, to cost about $400,000.

## Pacific and Mountain States

ANACORTES, WASH.—Plans are being prepared by the E. K. Wood Lumber Company for the erection of a new mill, with power plant and machine shop, at Burrows Bay, to cost about $400,000.

OLYMPIA, WASH.—The County Commissioners have granted the Olympia Light & Power Company permission to extend its lines into the Pleasant Glade district to furnish electrical service.

QUINCY, WASH. — The Washington Water Power Company plans to erect a 13,000-volt transmission line from Moses Lake to Quincy (20 miles) to supply electricity for irrigation purposes to the orchards around Quincy.

SEATTLE, WASH.—Work will soon be started on the erection of the 105-mile transmission line from the Skagit River (municipal) hydro-electric project to Seattle. C. F. Uhden is chief engineer of the work.

TACOMA, WASH.—Plans are under consideration by the Municipal Electric Light Department for the erection of a substation on the Wapato Hill reservoir site to distribute electricity in the South Tacoma district.

VANCOUVER, WASH. — The Columbia River Paper Mills, Inc., is preparing plans for its proposed new plant, including power house, to cost about $500,000.

ALBANY, ORE.—Extensive improvements are contemplated by the Mountain States Power Company, including the erection of a transmission line from Prospect to Springfield. The cost of the work is estimated at about $200,000.

INDEPENDENCE, ORE.—The Mountain States Power Company plans the erection of a transmission line from Albany to Independence, to cost about $60,000.

KLAMATH FALLS, ORE.—The California-Oregon Power Company contemplates erecting a 66,000-volt transmission line from Algoma to Chiloquin, a distance of 22 miles, to serve the latter town and the sawmills in that district.

METOLIUS, ORE.—The Federal Power Commission has granted the Columbia Valley Power Company a preliminary permit for the development of the Metolius power site.

CONCORD, CAL.—The Pacific Gas & Electric Company contemplates extending its transmission lines into the Concord Burgess district, east of the town.

DAVIS, CAL.—The Pacific Gas & Electric Company, San Francisco, has acquired a site in Davis on which it will erect a power house, machine and repair shop and other buildings, to cost about $100,000.

LE GRAND, CAL.—The San Joaquin Light & Power Corporation, Fresno, plans to erect a 70,000-volt transmission line in this section. A new substation will be built for service in the eastern sections of Merced and Madera Counties.

LIVERMORE, CAL.—Bids will be received by the director of the United States Veterans Bureau, Arlington Building, Washington, D. C., until March 29 for the construction of a tuberculosis Hospital at Livermore, including all buildings, heating, ventilating, electric work, etc.

LOS ANGELES, CAL.—An ordinance is being arranged for the installation of an ornamental street-lighting system on Arden Boulevard, Third Street and El Centro Avenue.

LOS ANGELES, CAL.—The California Cyanide Company has been organized by the officials of the Air Reduction Corporation, 342 Madison Avenue, New York City, and F. W. Braun of the Braun Corporation, New High Street, Los Angeles, to erect a plant here for the production of sodium of cyanide and kindred products, to cost about $500,000. The proposed work will include a power house and machine shop.

NEWMAN, CAL.—The National Ice & Cold Storage Company will install electric power equipment at its proposed ice-manufacturing plant, to cost about $100,000.

PORTERVILLE, CAL.—Steps have been taken by the Chamber of Commerce for the installation of an ornamental lighting system on Main Street.

SACRAMENTO, CAL.—Plans are under consideration for the installation of fire and police signal-alarm systems.

SAN FRANCISCO, CAL.—The Pacific Gas & Electric Company is preparing plans for the construction of five substations in different parts of the city, to cost about $800,000.

TRACY, CAL.—The Chamber of Commerce is securing estimates of cost for the installation of an ornamental lighting system on Central Avenue and Sixth Street.

BOISE, IDAHO.—Plans have been completed by the Idaho Power Company for extensions to its power plant on the Snake River at American Falls, to cost about $1,000,000. The work will include an addition to power house and the installation of two new generating units having a total capacity of 17,000 hp.

CHANDLER, ARIZ.—An election will soon be held to vote on the proposal to issue bonds for the installation of a municipal electric distribution system and an ornamental street-lighting system. It is proposed to purchase energy to operate the system.

GRAND JUNCTION, COL.—Arrangements are being made by the Grand Junction Electric, Gas & Manufacturing Company for resetting a 268-hp. Heine boiler in reinforced-steel concrete boiler frame and for erecting a new fireproof power house. A. E. Anderson is general superintendent.

## Canada

ST. JOHN, N. B.—New tenders, it is stated, will be asked by the City Council for switching equipment and for heating and lighting the civic substation.

LONDON, ONT.—The erection of 18 to 20 miles of rural transmission lines in London Township is under consideration by the Public Utilities Commission.

WALKERVILLE, ONT.—The local Hydro-Electric Commission has petitioned the Town Council for an appropriation of $25,000 for extensions to the system. Plans have been approved by the Town Council for the installation of electric lamps on Wyandotte Street, to be maintained by underground wires, to cost about $12,000.

# Electrical Patents

**Announced by U. S. Patent Office**

(Issued Feb. 13, 1923)

1,445,589. Lock; K. Horiguchi, Tokyo, Japan. App. filed July 9, 1921. Magnetic lock.

1,445,600. Electric Heater; J. Lavoie, Montreal, Can. App. filed Nov. 25, 1921. Combined cooking unit and room heater.

1,445,610. Adjustable High Resistance; C. P. Brockway, Toledo, Ohio. App. filed June 14, 1920. High-resistance shunt across the condenser located in series with grid electrode of audion.

1,445,613. Detector; H. P. Donle, Meriden, Conn. App. filed April 6, 1922. Contact-type detector for radio signaling.

(Issued Feb. 20, 1923)

1,445,636. Method of and Means for Indicating the Frequency Alterations of an Alternating Current; A. Meissner, Berlin, Germany. App. filed May 3, 1922. Apparatus for measuring radio frequencies.

1,445,640. Pole-Carrying Ring for Electric Apparatus; T. E. Murray, Jr., and J. B. Murray, Brooklyn, N. Y. App. filed April 6, 1921. Stamped sheet metal with segments welded together.

1,445,644. Material for the Production of Carbide; J. H. Reid, Pittsburgh, Pa. App. filed Oct. 23, 1919. Calcium-oxy-compound and cokable carbonaceous material reduced in electric furnace.

1,445,645. Process of and Material for the Production of Metal Hydrates and for the Production of Gas; J. H. Reid, Readsboro, Vt. App. filed Jan. 27, 1921. Coke from gas retort reduced in electric furnace.

1,445,665. Electric Lighting Fixture; E. L. Dales, Philadelphia, Pa. App. filed March 9, 1922. Reflector over end of lamp and one around lamp.

1,445,678. Rheostat; A. C. Gilbert, New Haven, Conn. App. filed Jan. 28, 1918. Designed for base of electric fan.

1,445,706. Electric Heater; A. Papini, Philadelphia, Pa. App. filed Oct. 15, 1919. Vacuum chamber on rear of reflector prevents escape of heat.

1,445,707. Circuit Controller for Electric Heaters; A. Papini, Philadelphia, Pa. App. filed Oct. 15, 1919. Device opens circuit when pedestal occupies any position other than normal

1,445,731. Transmission System; H. J. Van Der Bijl, New York, N. Y. App. filed Sept. 30, 1918. Three-electrode tube combined with two-electrode tube for amplifying radio signals.

1,445,759. Means for and Method of Testing Multiplex Carrier Circuits; J. Davidson, Jr., Montclair, N. J. App. filed Sept. 25, 1919. Testing the transmission efficiency of apparatus.

1,445,811. Apparatus for Exhausting Incandescent Electric Lamps and Similar Articles; M. P. Wetmore, Newark, N. J. App. filed Nov. 5, 1918. Rotary air pumps on rotating table successively place evacuated lamps before operator.

1,445,829. Telephone Rest; C. Fischer, New York, N. Y. App. filed July 21, 1921. Attachable arm for holding receiver to ear.

1,445,855. Trolley-Wire Frog; G. D. Slaymaker, Detroit, Mich. App. filed Jan. 12, 1922. Provided with adjustable renewable runners.

1,445,860. Apparatus for Treating Metals; J. S. Turek, Cicero, Ill. App. filed May 13, 1921. Electric furnace of tilting type used for refining, melting or heat-treating metals.

1,445,885. Commutator; A. J. Hix, Hellier, Ky. App. filed July 13, 1922. Method of soldering leads to segments.

1,445,896. Variable Inductance; M. C. M. Lane, Roselle Park, N. J. App. filed June 2, 1922. Combines all functions of variometer, variocoupler and variable inductance.

1,445,897. Electric Heater; E. N. Lightfoot, New York, N. Y. App. filed March 8, 1920. Resistor enclosed by and insulated from sheet metal armor.

1,445,919. Electrical Coil Unit; D. Stone, New Rochelle, N. Y. App. filed March 25, 1922. Movable end attachment to secure accurate resistance value.

1,445,924. Electrical Connector; R. E. Williams and H. H. Moreton, Los Angeles, Cal. App. filed April 9, 1920. For lamps, spotlights, and similar devices.

1,445,929. Electrical Apparatus; W. R. G. Baker, Schenectady, N. Y. App. filed Oct. 7, 1920. Wireless transmission system employing two electron tubes.

1,445,933. Dynamo-Electric Machine; J. L. Burnham, Schenectady, N. Y. App. filed July 19, 1920. Poles in which magnetic material not only carries magnetic flux but also exciting current.

1,445,961. Electrolysis Apparatus; P. M. Kree, New York, N. Y. App. filed Oct. 15, 1918. Depilatory apparatus.

1,445,967. Cigar Lighter; J. C. Lehmann, Jamaica, and G. H. Timmerman, Brooklyn, N. Y. App. filed Jan. 13, 1922. Induction coil spark used to ignite wick.

1,445,978. Stationary Induction Apparatus; H. O. Stephens, Pittsfield, Mass. App. filed April 30, 1921. Electric furnace transformer with multiple connected windings.

1,445,988. Method and Apparatus for Rectifying High-Tension Alternating Current; G. A. Witte, Philadelphia, Pa. App. filed April 8, 1919. Mechanical device operated in synchronism with alternating current makes and breaks connection between supply circuit and load, giving unidirectional impulses.

1,445,992. Cutting Machine; J. S. Cameron, Montreal, Canada. App. filed Sept. 24, 1921. Prongs electrically heated to temperature that will cut through material without tearing.

1,446,005. Rotary Converter; H. F. T. Erben, Schenectady, N. Y. App. filed Oct. 17, 1913. Method by which commutating field strength may be automatically adjusted.

1,446,029. Liquid-Treating Instrument; F. E. Beidler, New York, N. Y. App. filed Sept. 9, 1921. Electric heater for small receptacles

1,446,106. Contact Shoe for the Third Rail of Electric Cars; W. A. U. Seltzer, Philadelphia, Pa. App. filed Nov. 25, 1922. Shoe provided with side roller member engaging beneath or upon third-rail.

1,446,133. Railway Signal Lantern; P. J. Sloan, Denver, Colo. App. filed Dec. 27, 1921. Electric lantern with differently colored bulbs.

1,446,135. Insulator; L. Steinberger, Brooklyn, N. Y. App. filed March 15, 1917. Pin-type insulator with four petticoats.

1,446,153. Method of Making High-Speed Steel; W. B. Brookfield, Syracuse, N. Y. App. filed Dec. 29, 1920. Subjecting material to continuous heat of electric furnace.

1,446,166. Variometer; C. R. Dumble, Arlington, Mass. App. filed July 24, 1922. Spherical type.

1,446,170. Electric Arc Welding Machine; J. W. Fay, Milwaukee, Wis. App. filed March 25, 1920. Two arcs operated in welding joint or seam, one being used for welding one portion of the seam and the other for welding remaining portion.

1,446,182. Clock; W. A. Hicks, Cincinnati, Ohio. App. filed May 10, 1921. Electrically operated clock.

1,446,234. Thermotelephonic Receiver; A. Williams and L. D. Williams, London, England. App. filed April 24, 1920. Arrangement of metal foil improved.

1,446,246. Means for Recording and Reproducing Sound; L. de Forest, New York, N. Y. App. filed Sept. 18, 1919. Sound waves recorded on photographic film similar to motion-picture film.

1,446,317. Electrical Liquid Heater; W. Penzold, Hanover, Germany. App. filed May 22, 1922. Electric steam generators.

1,446,318. System for Electrically Heating Liquids; W. Penzold, Hanover, Germany. App. filed Aug. 5, 1922. Liquid heated by electric current flowing through it.

1,446,385. Aircraft Landing Station; E. C. Hanson, Washington, D. C. App. filed March 5, 1919. Radio compass signal system to guide airplanes in flight and in landing.

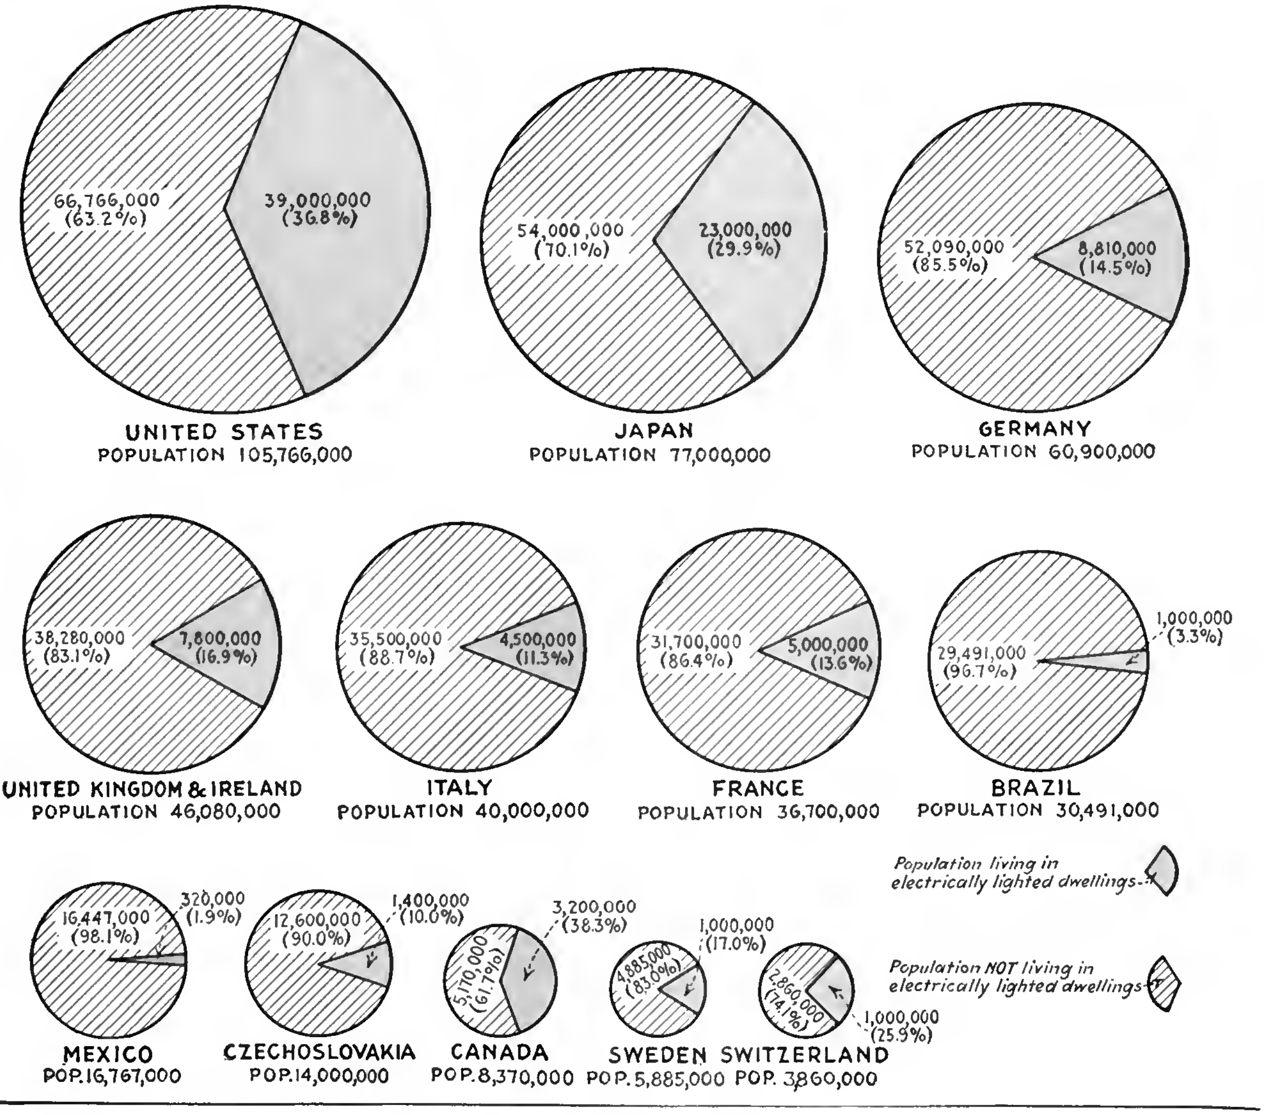
1,446,433. Circuit Arrangement for Indicating the Deviation of a Sender from a Desired Frequency; W. Schaffer, Berlin, Germany. App. filed Aug. 3, 1922. For wireless transmitting work.

1,446,436. Machine Synchronizing System; F. Stevens, Philadelphia, Pa. App. filed Sept. 30, 1920. Means for controlling speed relations between any driven machine and one or more other independently driven machines intended to be operated in conjunction.

# Business Facts for Electrical Men

Selected Statistics Presented Graphically for the Use of All Interested in Analyzing the Trend of the Electrical Business

## Only 111,822,000, or 6.5 per Cent, of the World's Population Live in Electrically Lighted Dwellings



## A Test of Civilization

DEGREE of civilization is judged by certain standards. One of these is the extent to which home life has been developed. The general adoption of home comforts and domestic labor-saving devices places a nation upon a high plane of civilization. This is particularly true of the use of electrical energy in the home. Nations which are recognized as the leaders in modern civilization will be found to be rated high in the percentage of their inhabitants living in electrically lighted dwellings. Such peoples have at their beck and call a source of comfort in the way of light, heat and power which has a strong tendency to elevate the mental and moral standards of the community. It may be stated with confidence that the central station bids fair to be one of the greatest civilizers in the world's history.

## The Rise in Construction Costs

THE gradual rise in the cost of construction materials which has taken place during the past eleven months is playing a large part in holding back the rapid return to normal industrial conditions. Many construction projects which last fall appeared certain of realization in 1923 are being held up on account of the excessively high cost of material and labor. In February the cost of general construction was 26.4 per cent above that of March last year and was only 25.2 per cent under the high record figure of June, 1920. A very large part of this is due to the increased wages demanded by labor, but the cost of construction material has also shown a decided upward trend. What effect this adverse condition will have on the sales of electrical apparatus and supplies as well as on new consumers of electrical energy is problematical, but it is a condition which will bear careful watching by the industry.

Electrical World

*The consolidation of Electrical World, Electrical Engineer and American Electrician*

Published by McGraw-Hill Company, Inc.

W. H. ONKEN, JR. Editor HAROLD V. BOZELL Editor

*Volume* 81 New York, Saturday, March 17, 1923 *Number* 11

# Allies of Industry

FINANCED by private capital and not by the public treasury, managed by business men selected by people who have put their savings into the service of the public, and regulated in the public interest by public authority, our utilities are today essential allies of industry. What kind of allies does industry want? It doesn't want weak, anemic, crippled, halting, shriveling, broken-down, "busted" allies—it wants them strong, alive, dependable, on the job 8,760 hours per year, if, as and when needed, progressive and growing!

As Vice-president Hall of the American Telephone & Telegraph Company recently told the Boston Chamber of Commerce in speaking upon this theme, public utilities must be prosperous if they are to be strong. Now, a prosperous public utility is not the same thing as a prosperous industrial or mercantile corporation. An electric service company or a transportation company cannot fill the valleys of the lean years from the large profits of the good years. All it can ask and all it does ask is money enough to pay good, fair, reasonable wages to the men and women engaged in giving its service; a good, fair, reasonable return for the capital necessary to provide the service; enough money to pay all its bills, and only one thing more—a narrow margin just wide enough to give a cushion of safety to maintain its credit.

If utilities prosper, they never prosper at the expense of the public. If they fail to prosper, they fail to prosper always at the expense of the public. As allies—yes, agencies—of industry they render a fundamental service on which modern civilization is built.

New money does not come in to make *more* money for present investors. These are limited to a reasonable return. The new money is needed just to "carry on," to provide the service demanded by the public, to do the job as the community wants it. The ability to get this money depends on one thing, assuming reasonably good management—credit. Credit means just a good, fair, decent, able-bodied margin or surplus to come and go on after expenses are met. The only real mistake utilities can make is by having rates even a little bit too low. The damage that is done by too low rates is stupendous compared with any little temporary saving through rate reductions. What the public pays for service is not a horse trade. This relation is a permanent, livable one whereby public and company can work together for each other's benefit from now on, and not on the outworn theories of twenty-five years ago. And the greatest reward for service rendered is not money, but appreciation by the customers of the utility. This appreciation warms the heart of the utility worker and strengthens his power to serve.

# Matthew Orpheus Troy

*A sales executive whose masterly application of the principles of engineering to commercial problems is helping the industry to attain higher planes of efficiency.*

IN THE extreme specialization of the present age it is out of the ordinary to find in a single individual the talent for high leadership in both technical and commercial fields. Matthew O. Troy, manager of transformer sales for the General Electric Company, combines to an unusual degree these qualities. He is a sales executive of wide reputation, an inventor and designing engineer, and relatively few men illustrate so well the possibility of completely harmonizing technical and sales problems. Mr. Troy's work in a national way along the line of transformer standardization and the reduction of excess sizes and ratings has accomplished the conservation of material and labor to a degree difficult to estimate. A trained engineer with a strong penchant for sales work, he has for more than twenty years been intimately concerned with the advance of transformer design and application along sound lines. To him is credited the original idea of organizing a sales force of transformer specialists who assist the general salesmen in the field, a development in sales management which has found wide acceptance in other branches of the electrical industry.

Mr. Troy was born in Burlington, N. C., in 1872 and was graduated from the University of Virginia in 1896 with the degree of B. S. in electrical engineering. He entered the testing department of the General Electric Company in Schenectady a year later and shortly thereafter was transferred to Lynn, Mass., where he was soon made foreman of transformer tests. In 1898 he was associated with Prof. Elihu Thomson and Richard Fleming in pioneer work on constant-current transformers.

In 1901 Mr. Troy was made assistant engineer of the Lynn alternating-current engineering department, but shortly thereafter was transferred to the transformer sales department at the Schenectady works. In 1910 he became head of the department. Throughout his sales work Mr. Troy has always been a close analytical student of engineering design.

Mr. Troy has been a leader in the Pittsfield and Schenectady Sections of the A. I. E. E. He is chairman of the service voltage sub-committee of the electrical apparatus committee of the National Electric Light Association and chairman of the joint conference committee of the Electrical Manufacturers' Conference and the N. E. L. A. on service voltages. For a number of years he has been chairman of the transformer section of the Electric Power Club. He has, besides, found time to be a frequent contributor to the technical press of the country.

Volume 81 Number 11

### Water Power of Navigable Streams Is the Nation's

ALFRED E. SMITH, Governor of New York, is a stalwart and likable man whom multitudes of his admirers hope some day to see in the White House. Much to his credit, he deprecates this idea and asserts that his only present desire is to do his duty as Chief Executive of the Empire State. His sincerity can be doubted by no one without reflecting likewise on his intelligence, for surely no intelligent man whose heart was set on being head of the nation would proclaim a belief that power from Niagara Falls or the St. Lawrence must never be allowed to cross the boundaries of New York. As well might Pennsylvania announce that it will consume all its anthracite coal, Montana all its copper or Kansas all its grain. The news columns of last week's ELECTRICAL WORLD presented the contrasting views of Governor Smith and Guy E. Tripp in this matter, Mr. Tripp indicating that the Governor's conception of hydro-electric service is sixteen years behind the time and that only by interconnected systems transcending state lines can its full benefit to the nation be realized.

Mr. Smith was born in New York City's East Side, and one reason for his popularity is that, unlike most men who rise from poverty to prominence, he still keeps his home among the scenes of his early struggles. Every one likes him for that, and every one admires his democratic spirit. But, just as he has in state affairs acquired an outlook far broader, even if less picturesque, than can be afforded by the Bowery or the sidewalks of New York, so, if he is to develop into a national leader, he must learn to look beyond the boundaries of his state. In this great nation, indissolubly welded by centripetal forces, state's rights are no longer a shibboleth by which to conquer. We prosper and thrive through free and unlimited co-operation, and each state is proud to share its resources with all the others. In this regard the attitude of Governor Pinchot of Pennsylvania on water-power development stands out in refreshing contrast to that of Governor Smith of New York.

### Radio Interference or Radio Co-ordination?

SECRETARY HOOVER'S second radio conference, scheduled for March 20, should result in some constructive agreements which will make possible a wider utilization of radio with full co-ordination of the various radio facilities of the country. This should surely be so if the conferees approach their task on the basis of "co-ordination" rather than on that of "interference." Though the terminology may not, technically, have a great deal of significance, the psychology of the appeal to co-ordinate or co-operate should mean a stronger effort to reach a common agreement than can spring from a state of mind where elimination of "interference" is the uppermost thought and where every person is strongly on guard in his own particular domain of ether waves.

It is, of course, recognized that there are commercial considerations, pride, priority and many other intangible though forceful elements in the problem, yet in the end the technical solution of the instrumentation of stations must decide what can and cannot be done. With the rapid advance in the science and the art of radio—the greater ability to confine radiant energy to limited wave bands and to control direction, the increased sensitivity and selectivity of receiving sets, and the more intimate knowledge of the peculiar radio characteristics of certain parts of the country—there is no doubt that the technical problem of allowing full opportunity to every legitimate radio use will be adequately solved. As the term "inductive interference" has given way with advantage to "inductive co-ordination," so let the radio problem be approached not as one of "radio interference" but as one of "radio co-ordination."

### Midnight Oil Must Still Be Burned to Keep Up with Progress

EVERY time a practicing electrical engineer decides that he knows enough theory for sound judgment in his particular branch of the profession he is rudely awakened by an unexpected advance in scientific and technical knowledge, a new set of phenomena that bear directly upon his problems, an unexpected application of some obscure physical relationship, a new terminology, an important new mathematical method, or what not. Hardly a year passes without a progressive engineer having to face the dilemma of again burning midnight oil or being relegated into the class of "has beens."

It seems like a big step from the ancient bellhanger to a modern superpower expert, and yet the progress has come in imperceptible installments most of which are within our memory. Beginning with Ohm's law for direct current, the transmission engineer had to absorb trigonometry, inductance and capacity, to swallow transients, ionization theory, polyphase relationships and catenary curves, and to learn to look blasé when hyperbolic functions and complex quantities were mentioned. Now something new is about to be sprung on him in the form of decremental vectors due to a complex angular velocity of rotation.

A decremental vector, it is asserted, is one which rotates uniformly, like the old ones used to do, but at the same time decreases in size. If it increases in size, it is to be called incremental. To get a simple idea of a decremental vector one must think of a rotating flywheel with a bug creeping leisurely along one of its spokes toward the hub. The distance between the center of the wheel and the bug is then a decremental vector because it revolves uniformly and at the same time decreases in size. Furthermore, the particular

kind of decremental vectors of importance in the study of electrical transients is one whose length decreases in a geometric progression. It means that when the bug is, say, three feet from the wheel center it should creep at one-half the speed at which it creeps when six feet from the center. The bug thus describes a logarithmic spiral in space, whether it wishes to or not.

At the recent midwinter convention of the American Institute of Electrical Engineers decremental vectors were treated in at least four papers, at three different sessions, and were discussed by two manufacturing engineers, an operating engineer and two professors. Unless a sordid conspiracy existed, the admission is forced that such vectors must be useful in the understanding of and in the calculations relating to transient conditions in transmission lines, in transformers and in rotating machinery. Next it will be necessary to get posted on the new notation and on the properties of such vectors, lest there soon shall be another category of papers which the uninformed simply cannot read beyond the title and the acknowledgments at the end.

### Needed Changes in Wiring Code Rules

THIS ought to be a happy week for the electrical industry, particularly for the electric light and power companies and the electrical wiring contractors. At the biennial meeting to revise the National Electrical Code held in New York this week the Underwriters abolished the 660-watt limitation on circuits, permitted the installation of a solid neutral and also sanctioned the use of a 15-amp. fuse on 125-volt branch circuits. For years these changes have been proposed, but no action has been taken until now. Naturally the Underwriters are slow to move in matters affecting fire hazards, but there is such a thing as being too cautious, and the Underwriters are inclined to stand so straight at times that they lean backward. That they have sensed the handicaps of some of their rules on household electrical devices augurs well, and that they have acted accordingly is even better.

### The Specifications of 1914 Are Retired

THE adoption of the National Electrical Safety Code as an American engineering standard has placed a more or less effective ban on most of the specifications for overhead-line work that have hitherto been used, particularly in the cases where crossings and conflicts are involved and utility-regulating bodies may be called upon to take a hand. By its formal withdrawal of the "1914 specifications" the overhead-systems committee of the National Electric Light Association removes more of the specifications that have been superseded but, because of the lack of authoritative action, have remained to confuse those called upon to make use of specifications for line construction.

It would be well if the other technical bodies having specifications of this kind which have become more or less obsolete because of the presence of the safety code in the field would take action similar to that of the N. E. L. A. and clear the slate of specifications that will only be a source of controversy so long as they have some sort of official standing. A method of revising the safety code has been provided in the routine of the American Engineering Standards Committee, and the place to stage any discussion of matters that may affect line construction and modify the code is through that routine and not by the maintenance of separate specifications which some one must try to thrust down the throat of the electrical industry. The thrusting process results in bad feeling and controversy that do not help in the final solution of line-construction problems where conflicts between the lines of two or more utilities exist.

### The War-Learned Lesson of Excess Varieties

WHILE the nation was struggling to win the war many simple truths were uncovered that had long lain buried, but many of them apparently are being covered up again. The principle of simplification, for instance, was found and recognized and shown to all the people and was adopted by industry, and the manufacturers of America made great strides in the elimination of excess varieties and the reduction of waste. One large firm that builds a certain piece of machinery used in power stations was when the war began manufacturing sixty-odd modifications of that machine, but when the pinch came and economies were demanded a conference of executives was held and the sales manager recommended simplification. The president, filled with pride for his line, argued against it; but the meeting voted for this obvious economy and the line was gradually cut to three modifications of the machine only. And the same policy was applied to other products until the plant was 80 per cent occupied with staples.

As times grew bad after the war the eagerness for business, the demands of customers and the importunities of salesmen gradually broke down this economic principle, and the plant began to turn out more varieties, until today the company is taking orders for almost anything that customers call for. A manufacturing plant has been turned into a job shop with resultant high prices to the consumer. It is a typical case, and yet this manufacturer knows and admits, as other manufacturers must know, that the best way in the world to cut down costs is to save waste on bad habits and that carrying excess varieties is economically as bad a habit as a man can have.

Turning the back on simplification and ignoring the undoubtable demonstration which the war gave of the effectiveness of this fundamental principle of industry do not alter the position of the manufacturer today nor the needs and rights of those he sells to. How can any manufacturer justify the presence of excess varieties in his catalog? It is his responsibility and his job to weed them out.

### Kelvin's Law Should Not Be Misinterpreted

LORD KELVIN was a pioneer in engineering economics, and few realize to what an extent he studied the subject. His findings and the use that has been made of them constitute a lesson in what should and what should not be done in engineering.

What is commonly known as Kelvin's law declares that "the most economical size of conductor is that for which the annual charge on the investment is equal to the annual cost of energy losses." This statement, though probably made by Lord Kelvin, was not made without due reservations by him. It is well recognized that it is true only in some very specific cases and is in no way general. However, many have used it for solving

general problems because it seemed convenient and because they did not recognize the necessity for doing a thorough piece of work. Lord Kelvin, however, as his own writings attest, believed that a thorough study of all factors entering into the problem of design of a line must be made and that from such a study alone an economical solution could be attained.

The paper by P. O. Reyneau and H. P. Seelye in this issue emphasizes that fact and points the way to a thorough and complete study of the problem of designing a distribution line. The wire is but one part of a distribution system, and it should be evident that no economical design can be obtained if none of the other elements that enter into line construction are taken into consideration. The lesson to be drawn from the application of Kelvin's law is that an indiscriminate use of laws and rules whose exact application is not thoroughly understood will not produce sound results and is not engineering.

### How to Co-operate with the Farmer

IN COMMENTING on efforts now being made to bring together the organized farm interests and the electrical industry in a study of the use of electrical energy on the farm Philip S. Rose said, in a recent issue of the *Country Gentleman*: "This is a kind of co-operation that brings results. It gives the farmers first-hand inside information of what is going on in the minds of those whom they depend upon for service. It enables the farmers to present their views in court where they will have a respectful, sympathetic hearing. Such a policy should result in a happier understanding of the problems both parties are obliged to meet."

Mr. Rose's article is a fair and commendable statement of the entire problem written from an agricultural viewpoint. In it he points out some of the pitfalls that must be looked for in the establishment of the service, winding up by saying: "The rural market is a big one and needs developing. There may be no big immediate profits in it as there have been in city and industrial development, but it is necessary for the healthy growth of the entire country. It will not pay for one-half the country to let the other half exist under half lights. The big power companies cannot afford to network the country with power lines and neglect the farmer. He will feel discriminated against and become bitter. There is thus involved in this problem not only engineering but a problem of politics and of social relationships that is even more important."

The last statement is one of which the electrical industry cannot afford to lose sight. The effort referred to by Mr. Rose is one that is only in its initial stages, but in which the National Electric Light Association is vitally interested. The organized agricultural interests involved view the farmer as a business man who must take his place among business men and cease to be classed with the radical and unstable elements in any way. With this viewpoint, co-operative work with the farmer in the effort to solve the problem of the use of electrical energy on the farm ought to progress rapidly. However, every central station ought to be in close relations with its own local agricultural organizations, looking the problem square in the face from all angles and seeking so far as possible to hasten the solution. A good way to do this is to get on intimate terms with the state agricultural schools, the county agent and the farm organizations back of him as representing the agricultural viewpoint. While they are interpreting this viewpoint to the central-station man, he in turn can be interpreting his own viewpoint to them. Mutual understanding thus built up will not only clear away many of the difficulties to be met but will be a valuable asset on both sides.

### Thermal Resistivity and Surface Emissivity of Cables

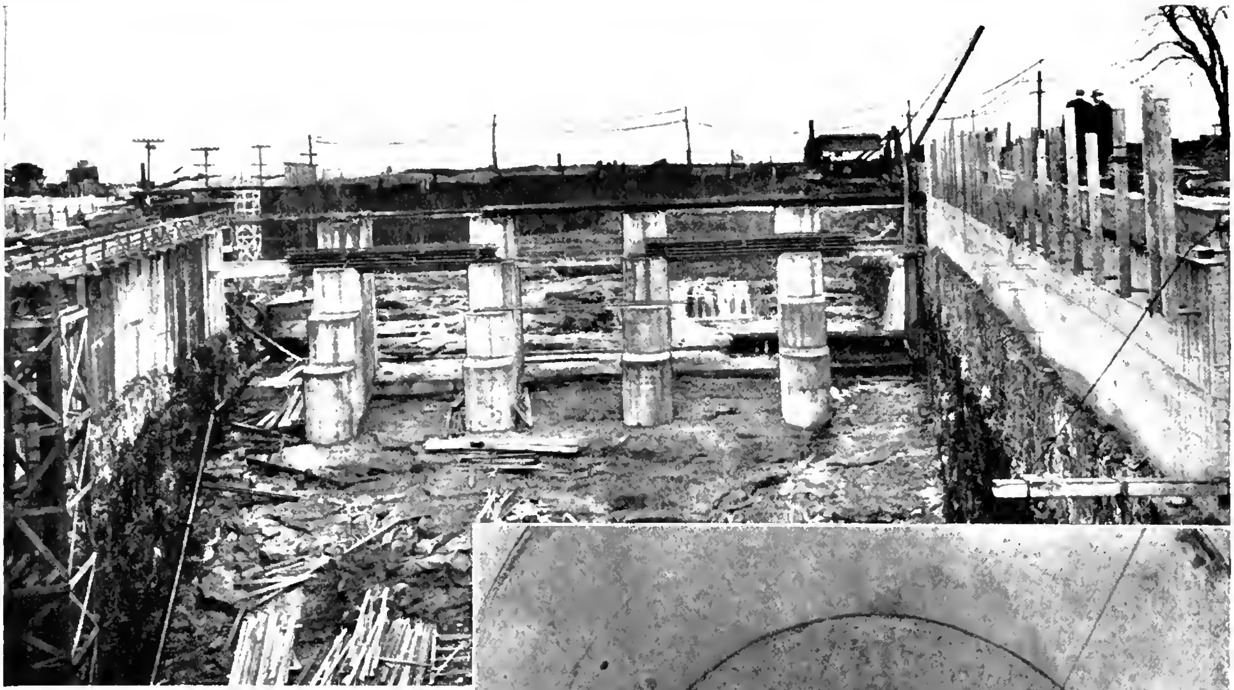
THE Biblical saying about straining at gnats and swallowing camels has been exemplified by some recent tests on lead-covered, paper-insulated power cables. A difference of 10 per cent in the carrying capacity of two apparently identical cables was caused by the differences in the thermal resistance of the insulation and in the amount of heat emitted by the lead surface. It is insisted in many cable specifications that the prescribed amount of copper should be correct within a fraction of 1 per cent, and yet nothing is usually said about the above-mentioned factors, which, as just stated, may affect the carrying capacity by ten times this amount. Seeing that the thermal resistivity clause is included in some British contracts, the time should not be far distant when makers and users of cables in this country will come to some reasonable standard agreement on this point.

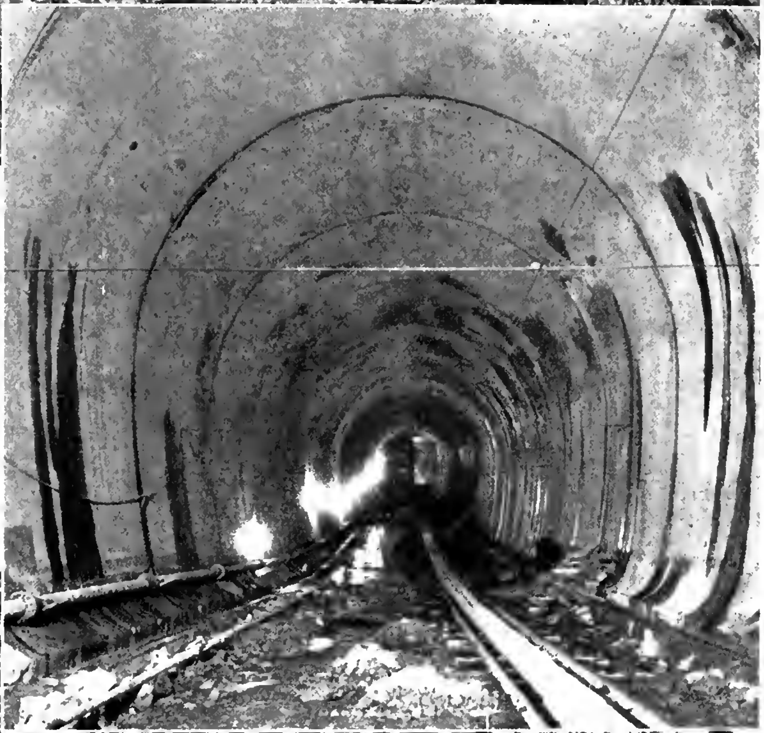
### Engineers Must Have Time for Forethought and Retrospection

IF THE distribution engineer is to do what should be done to eliminate the present wastes in distribution systems and bring them on a par with the economy of power stations, he must be provided with sufficient statistical help to work out ahead of time the possibilities and economy of the contemplated work. This does not mean that a statistical department especially for the distribution engineer must be supported, but it does mean that sufficient help must be provided to permit him or some of his staff to spare time from routine duties to devote to forethought, planning or retrospection.

Economies achieved are more self-evident in power stations than in distribution systems. In the power station the coal pile and other material, the payroll and the maintenance and interest charges tell the story of the cost per kilowatt-hour generated. In the distribution system results are not so immediately perceptible, and an analysis is necessary to make them clear, because the many factors involved vary continually in their cost and conditions vary greatly in different sections.

It was recently stated in these columns, in a letter by D. W. Roper, that the cable investment alone of the Commonwealth Edison Company is double that in turbo-generators. That economy in installing and operating such a system can be realized should be self-evident. But the possibilities of economies in the whole distribution system and the magnitude of the task of obtaining these economies are known only to those in close contact with the work. Means must be given them to prove their point either while they are doing their work or before they do it. A great deal is heard about the necessity of improved distribution-system conditions, and most managements are talking about it, but there is little evidence of a real appreciation of the engineer's requirements or of support for him in these problems.

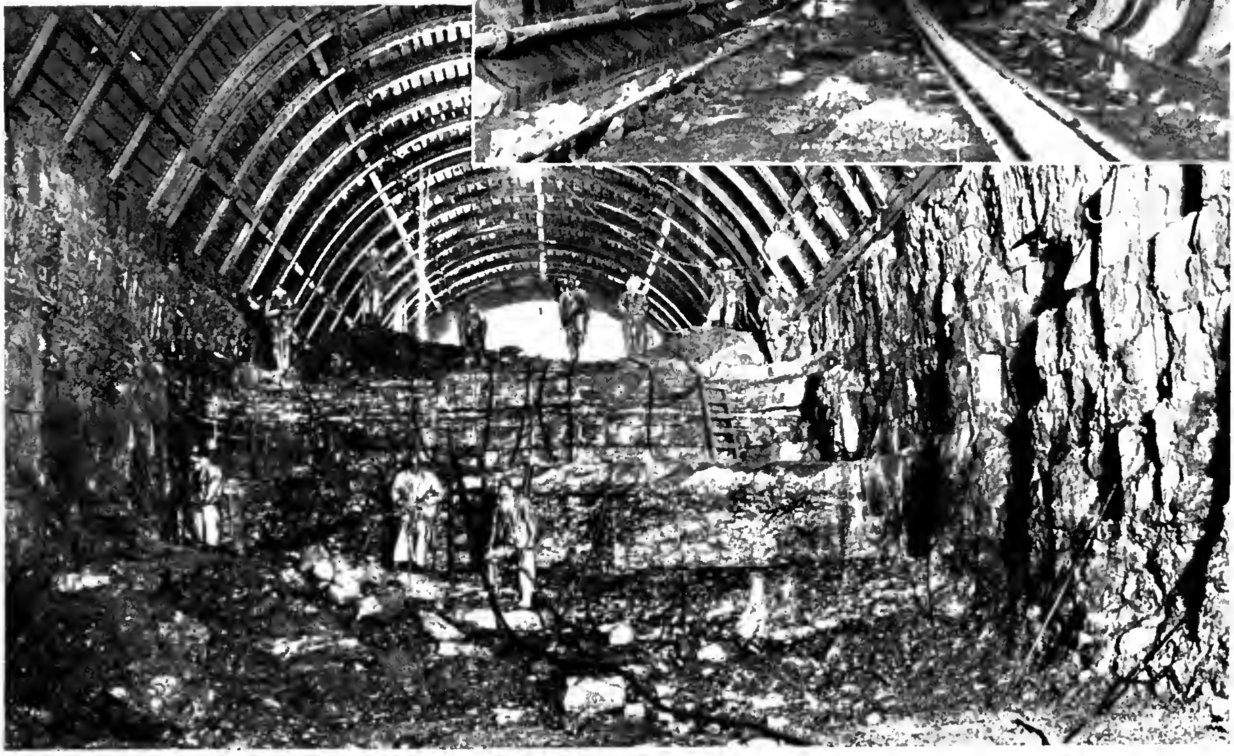




## New Pressure Power Tunnel of the Niagara Falls Power Company

THE improvement in efficiency, of which the construction of this new pressure tunnel is a part, will practically double the power which the water it carries will produce. It is excavated in solid rock for its entire length of 4,500 ft. Its cross-section is horseshoe shaped, having a maximum height of 32 ft., and a maximum width of 32 ft. measured inside the concrete lining, which is about 2 ft. thick. From its inlet at Port Day it dips to a depth of 120 ft., passes underneath to the city of Niagara Falls, and emerges near the brink of the Gorge about a half mile below the falls.

Engineers interested may inspect the tunnel between March 20 and April 1, if advance notification is sent to the Niagara Falls Power Company. It is expected that the tunnel will be filled with water by April 1.



# New Radial Relay Protection*

## Utilizes Excess-Current Relays with Current, Time and Voltage Elements to Insure Selective Operation on a Radial Transmission System

By P. ACKERMAN
*Electrical Engineer Shawinigan Water & Power Company
Montreal, Canada*

THE principle now employed for a radial distribution system makes use of the excess current in the line to indicate the abnormal condition of a short circuit, whereas selectiveness of tripping is obtained by time-delay difference on relays of switches located in series with each other between the point of fault and the generating station. This principle of protection is found to be entirely inadequate for transmission systems where the whole generating capacity is fed out over a few long lines.

A new principle has been developed which makes use of the fact that a short circuit manifests itself not only by excess current but also by low voltage. This fact is made use of so as to obtain a selectiveness of switches located in series, not only by time selective setting, but by a relay which will respond only if the relay is located close enough to the point of short circuit to insure that the voltage at that point will be so low as to offset the relation between voltage and current sufficiently to actuate the relay.

### THE 30-CYCLE SHAWINIGAN SYSTEM

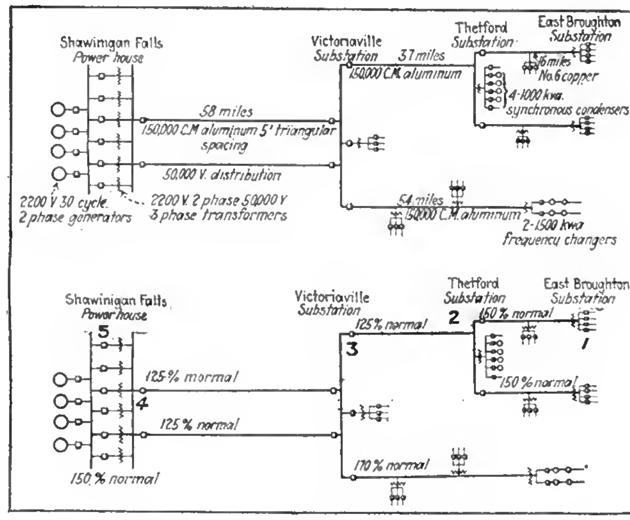
Fig. 1 shows a schematic single-wire diagram of the 30-cycle transmission system. The system is one of the oldest existing transmitting power at 50,000 volts. The power is generated at Shawinigan Falls as 2,200-volt, two-phase current. It is stepped up at the power house to 50,000-volt, three-phase current, and as such is transmitted over 150,000-circ.mil aluminum lines.

The system is particularly characterized by the comparatively large load of 25,000 kw. being transmitted over a distance of 110 miles with the small-size conductor and the comparatively low transmission voltage, the voltage drop under normal load being nearly 30 per cent. These features are particularly responsible for the rather limited short-circuit current in case of distant short circuits.

The generator capacity is liable to vary between 12,000 kva. and 35,000 kva., depending on load conditions, so that during light-load conditions line short circuits may be limited as to current magnitude on account of limited generator capacity. Two parallel transmission lines are feeding Victoriaville. If one of these lines is taken out of service, the total reactance between Shawinigan Falls and Victoriaville will double and as a result cause a further limiting of the short-circuit current in case of short circuits beyond Victoriaville.

Toward the end of 1918 a careful investigation was started on the system in question in an endeavor to improve the relay protective system. Up to that time ordinary bellows-type overload relays were employed with varied success. The result of the investigation led to the decision to equip the main system with a time selective excess-current protection, consisting of modern inverse definite-time relays of great accuracy and reliability.

The serious short-circuit current limitation in case of distant line shorts and under certain operating conditions was then already realized, but no effective means were then known to assure the same protection for all operating conditions. As a result a protection was developed which would offer fair effectiveness during heavy load conditions. In an endeavor to improve the ordinary time selective protection a com-



FIGS. 1 AND 2—SYSTEM DIAGRAM AND CURRENT SETTINGS OF RELAYS

Above is the schematic layout of the 30-cycle system. Below are the current settings adopted on various lines in per cent of normal maximum load current.

bination of time-limit and instantaneous relays was provided on each line. One set of relays consisted of the customary inverse definite time relays, set so as to be time selective with switches in series. The other set consisted of instantaneous excess-current relays of such high current setting that they would respond only to short circuits very close to their respective station.

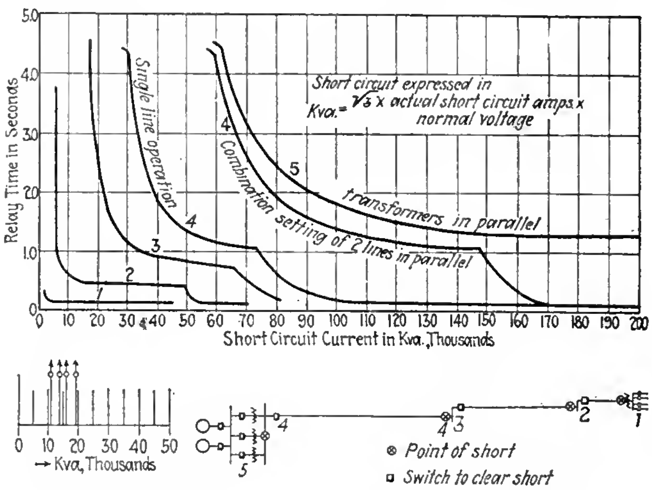
This combination protection assured quick clearance in case of most serious shorts. Such rapid clearance was essential in order to limit the damage at the point of fault and also to limit the seriousness of the disturbance, particularly in view of the sensitive synchronous load of the system. The combination protection also permitted shorter time settings, which was particularly essential in order to obtain at least some effectiveness from the excess-current protection. The settings were governed by the following considerations:

(a) The current setting of each time-limit excess-current relay must be in excess of the maximum load current of the respective line. This is necessary so as

*Paper read before the Montreal Branch, Engineering Institute of Canada, Nov. 16, 1922.

to prevent normal load current actuating the relays. Fig. 2 shows the current settings of the relays of the various line switches in relation to the normal load current of the respective line. Ordinary practice considers a current setting of at least one and a half to two times normal as minimum permissible current setting to avoid wrong tripping on account of momentary overload.

Fig. 2 indicates that most lines were provided with a current setting of less than one and a half times normal load current. These low current settings were somewhat dangerous, but it was realized that they were essential if at least some good were to result from the protection, owing to the limited short-circuit current to be expected.



FIGS. 3 AND 4—TIME CURVES OF EXCESS-CURRENT PROTECTION AND SUSTAINED SHORT-CIRCUIT CURRENTS UNDER MOST LIMITED CONDITIONS

The distant 2,200-volt local distribution feeders (see Fig. 2) were equipped with instantaneous excess-current relays (1). The line switch (2) had to be set time selective with switches (1) up to any maximum short-circuit current value which might be created by a short circuit beyond switches (1). It was calculated that such shorts would never exceed 45,000 kva., owing to the limiting effect from the transformer reactance. Short circuits on the 50,000-volt side of this line, however, could exceed the value considerably. Switch 2 was, therefore, equipped with an inverse definite-time relay having sufficient time lag up to shorts of 50,000 kva. to allow feeder switches (1) to clear ahead of the main-line switch (2). In addition to this time-limit protection, switch 2 was equipped with instantaneous relays of 50,000 kva., to effect a quick clearance of 50,000-volt line shorts. Thus time curve 2 was obtained for switch 2. Switch 3 in turn had to be time selective with switch 2. In this case the most critical point of the two time curves is the point where the instantaneous relay of switch 2 starts. Time curve for switch 3 had to be chosen so that at that point sufficient time difference would exist to allow switch 2 to clear a trouble on its own line before the relays of switch 3 would close contacts. Switch 3 was also equipped with an instantaneous protection for heavy short circuits close to its station, similar to switch 2. The time curve for switch 4 was determined in a manner similar to that given for switch 3.

Finally, transformer switches (5) had to be made time selective with line switches (4). In this case, however, the time curve had to be made time selective with respect to the combination setting of the two lines (4) operated in parallel. Time curve for the generator switch (6) was found to become so high that this protection was considered useless and was never installed.

The sustained short-circuit current values are shown for minimum condition of two generators and one line feeding to the extreme end of the system. The current values are the sustained values which would be created with short circuits at the extreme end of the respective lines. Comparing these values with the current settings of the respective line switches, it will be noticed that these values are all below the current setting of the respective line switches, with the exception of short circuit 2 cleared by switch 2.

(b) The time curves of the various relays were adjusted in such a way that under maximum short-circuit conditions, when two switches had to function selectively as to time, the switch closer toward the power house was given about 0.4 second additional time lag. Such time difference is necessary to allow a switch to rupture the current before the next switch toward the power house may be released by the relay protection. With the combination protection of inverse time setting for limited shorts and instantaneous settings for heavy shorts, the critical condition for time selective action exists always under a short-circuit condition, which reaches a current value of the magnitude of the current setting of the instantaneous excess-current relay.

This may be more clearly understood from an example. Fig. 3 shows the time curves adopted for the various switches.

The system of protection and settings, as shown in Fig. 3, was installed early in the spring of 1919. In addition to this time-selective excess-current protection, a double line protection and ground protection in conjunction with a ground selector were installed.

## Operating Results of Time-Selective Excess-Current Protection

The performance of the protection was carefully watched during the summer months of 1919. A considerable improvement could be noticed compared with previous conditions. It was, however, soon noticed that the protection was unable to function properly in case of distant line shorts. In several instances it happened that a trouble at the Thetford end which should have been cleared by switch 3 cleared very slowly or not at all, and as a result the short had to be cleared by the power-house operator pulling line switches (4), thus causing a total interruption.

Upon closer investigation it was noticed that this condition was particularly pronounced whenever one line only was in service between Shawinigan Falls and Victoriaville. Suspicion arose then that, apparently under the above operating condition, the sustained short-circuit current dropped below the current settings of the relay, and that it was for this reason that the relay was unable to clear the short-circuited line.

To verify this a short-circuit test was arranged, as per operating diagram (Fig. 5). Three generators with four step-up transformers were feeding over one line to Victoriaville into the Thetford line. A short circuit was thrown onto the system at Thetford and the relays of switch 3 were watched. The inverse definite time relay of the induction type started to move on the initial short-circuit current kick, which indicated that the initial current rush was in excess of the current setting of one and a quarter times normal load current. Before the relay disk reached the trip position its movement became slower and slower and finally stopped completely. This was an indication that the short-circuit current had dropped to the relay setting equal to one and a quarter times normal load current. Finally, the relay disk started to move backward, returning to its original dead position, which indicated that the final sustained short-circuit current had dropped even below the tripping value of the relay; in fact, from some other observations it could be noticed that the ultimate sustained short circuit had dropped even slightly below normal load current. All this happened within an interval of about two seconds.

The explanation of this apparently strange behavior is to be sought partly in the high reactance of the lines and partly in the short-circuit characteristics of generators in general. A dead short circuit at the terminals of a generator will cause a momentary current flow in the generator of up to ten times normal load current or more. This short-circuit current will, however, within one and one-half to two seconds, gradu-

ally drop to one and a half to two and a half times normal load current or less, depending on the characteristics of the generator. Fig. 6 shows a typical curve of the gradual decrease of the short-circuit current of a generator. This gradual decrease of the generator short-circuit current from a high initial value to an ultimate low, or so-called sustained, value explains the behavior of the relay in our short-circuit test.

The test demonstrated clearly that the sustained short-circuit current on the line under the given conditions dropped below normal load current. It was, therefore, clear that for such condition the principle of excess-current protection was utterly inadequate, since no such excess-current relay could naturally be given a setting low enough to be effective in case of shorts and still not operate under normal load conditions.

From the operating experience of the summer season 1919, it had also been realized that it was very unsatisfactory to have a protection which would only offer a fair effectiveness under maximum generator and load condition, whereas under light load of abnormal operating conditions the protection would be inoperative.

Fig. 4 shows how particularly inadequate the excess-current protection is with respect to light load conditions and with distant line short circuits.

From the foregoing it became evident that a new principle of protection had to be adopted before effective protection could be obtained for this system.

In the search for a new principle it was instantly realized that a new scheme had to take advantage of the fact that under short-circuit conditions low voltage existed. Normal voltage had to keep the current relay blocked, even if its setting were below normal load current, so that it would not operate under any circumstances on normal load current unless a short circuit existed at the same time, pulling down the voltage.

An attempt was made first to develop a combination protection, consisting of current relays and low-voltage relays. The complications and the difficulty of effective settings, however, were found to be so great that the idea was abandoned. After a few other fruitless attempts with alternate schemes, the principle of the so-called current potential overbalance protection was conceived. A thorough preliminary study disclosed the soundness of the new principle, and as a result it was decided to have the necessary relays developed and installed as a first trial installation on switches 3 and 4 of Fig. 2.

## THEORY OF THE NEW TYPE OF PROTECTION

A transmission line of a certain physical characteristic represents a certain impedance $Z$. If such line was short-circuited at the far end and voltage was built up at the station bus from which the line emanates, the relation between current in the line and the bus voltage would be expressed by $E = IZ$. In other words, the current in the line is proportional to the bus voltage. Referring to Fig. 7, as an example, it is assumed that the impedance drop of the line is 10 per cent of normal voltage with normal line current flowing in the line; that means that the line, short-circuited at its extreme end, would require 10 per cent of normal voltage at the station busbar to cause normal current to flow in the line. Any greater short-circuit current under the same condition would leave a proportionally higher voltage at the station busbar.

In case of a line short circuit closer to the station, the impedance of the circuit to the short-circuit point would become lower, and as a result less voltage would be left at the busbar, with the same current flowing in the line, compared with a far end short. On the other hand, a short circuit beyond the next substation would offer a higher impedance and in consequence would leave higher voltage for the same current.

A relay (see Fig. 7) consisting of a beam pivoted in the center and equipped at either end with a solenoid, one side being equipped with a current coil fed from the line and the other side having a potential coil fed from the station bus, could be adjusted with respect to current and potential coils in such a fashion that the magnetic pull of current and potential coil

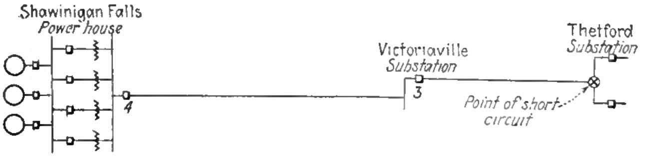


FIG. 5 (ABOVE)—OPERATING CONDITION DURING SHORT-CIRCUIT TEST WHICH PROVED INADEQUACY OF EXCESS-CURRENT PRINCIPLE

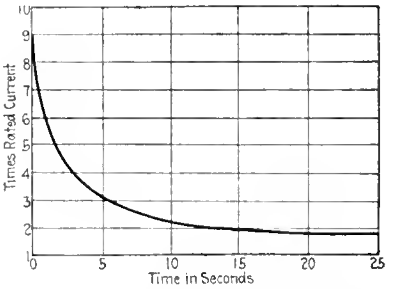

FIG. 6 (AT RIGHT)—TYPICAL CURVE OF TRANSIENT SHORT CIRCUIT ON THREE-PHASE GENERATOR

would just be equal under the condition of a short circuit at the extreme end of the line. A trip circuit arranged as shown would trip the line switch whenever the current coil would overpower the potential coil.

In our specific case of Fig. 7, the two coils could be adjusted for a balance of 10 per cent voltage against normal current. Such balanced condition would exist irrespective of the actual short-circuit current as long as the short circuit would be at the same point, since any change in the current coil would also produce a proportional change in the potential coil. A short circuit closer to the station, however, would leave a lower voltage on the potential coil of the relay, because of the lower impedance, and as a result would cause the current coil to overpower the potential coil and would thus trip the line switch. A short circuit beyond the end of the line would leave more than 10 per cent voltage per normal current, because of the higher impedance and, in consequence, the potential coil would overpower the current coil and would thus keep the trip circuit blocked. Under normal load condition, the potential coil, with full voltage across, will keep the current coil overpowered and will thus keep the trip circuit blocked.

From the foregoing it will be seen that the new type of protection has the following valuable features, none of which can be attained by the excess-current principle of protection:

1. Its actuation depends entirely on the relation between current and voltage irrespective of their actual magnitude.

2. The protection will be just as effective, therefore, for currents below normal load current; and in consequence the functioning can be made the same for all operating conditions and irrespective of the generator capacity.

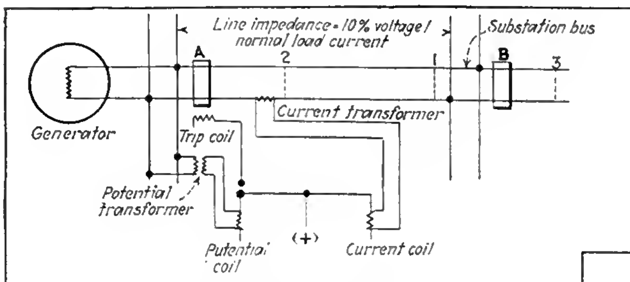
3. The actuation of the relay depends on the location

of the short circuit, so that its radius of action can be fixed. In consequence, selective action of switches in series can be obtained by limiting the active radius of the relay, instead of by time selective setting. Thus it is possible greatly to reduce the time settings of relay protection toward the power house.

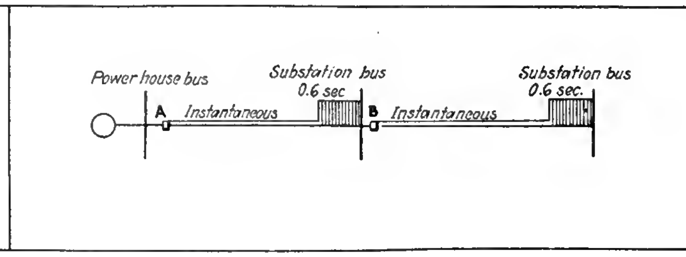
4. The protection is unaffected by load conditions and thus does not cause wrong tripping of line due to unexpected load increases.

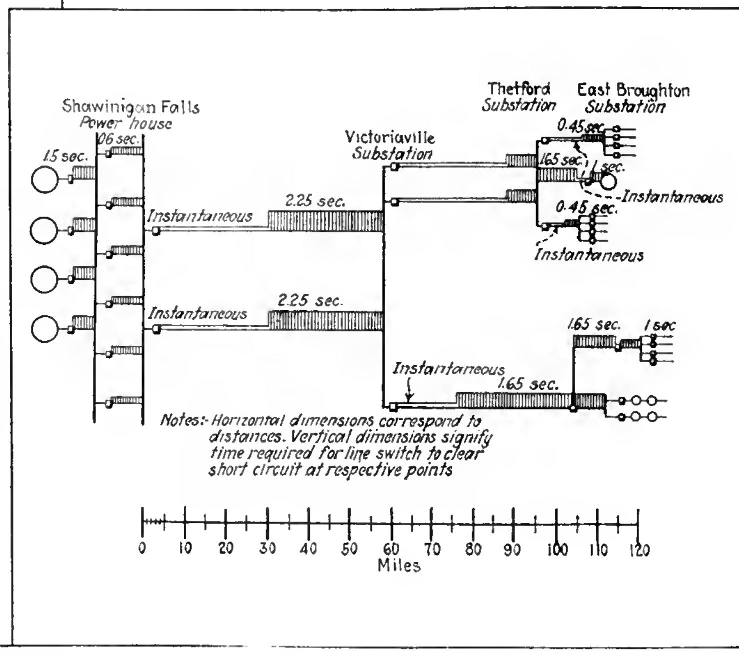
In the example of Fig. 7 it was assumed that the relay would be adjusted for such balance that it would just cover the short-circuit condition of the line end short. In actual practice no such accurate adjustment will thus assure effective tripping. As a result of this higher balance adjustment in the relay of switch *A*, its radius of action will extend into the line controlled by switch *B*. A short circuit at point (3) in that line would, therefore, be liable to trip switch *A* as well as switch *B*, if both were instantaneous. In order to prevent a wrong tripping of switch *A* under these conditions, switch *A* protection would have to be provided with a time lag sufficient to allow switch *B* to clear ahead of switch *A*.

In actual practice the selectiveness between the switches in series was solved by providing each switch with two sets of protection. One set is adjusted for a



| Condition | Relative Magnetic Pull on Solenoids | | Action of Relay |
|---|---|---|---|
| | Potential Coils | Current Coil | |
| Light load | | | Potential coil overpowers current coil and keeps trip circuit blocked |
| Full load | | | " " |
| Short at end of line at point 1 | | | Potential and current coils just keeping balance relay adjusted for this balance |
| Short near Power house at point 2 | | | Current coil overpowers potential coil and trips switch |
| Short beyond line at point 3 | | | Potential coil overpowers current coil and keeps trip circuit blocked |





FIGS. 7, 8 AND 9—CURRENT-POTENTIAL OVERBALANCE PROTECTION FOR ALTERNATING-CURRENT SYSTEMS

Fig. 7 (left)—Schematic diagram of current-potential overbalance principle for a single-phase circuit, with table showing functioning under different conditions. The principle of protection is based on an overpowering effect of current against voltage, irrespective of phase-angle relation. Any relay principle could be employed, therefore, in which current and potential produce mechanical forces which are proportional to the actual value of current and voltage respectively. The two mechanical forces thus created must cause opposing movements on a mechanical structure, so that movement occurs in direction of greater force. The induction principle, similar to the induction-type excess-current relay, could be used, having current and potential creating opposing torques on the shaft. Similarly the dynamometer principle could be used to produce opposing torques on a shaft.

In this case it was felt that a simpler and more rugged relay was obtained by using a beam pivoted in the center and with current and potential solenoid mounted on opposite ends of the beam. Thus the beam is pulled to the side of excess force. All relays were developed along this line. Current and potential coils were provided with taps so that different adjustments could be obtained. In this way any desired balance can be established by choosing such taps on the two coils that for a given current and potential value for which balance is to be created the ampere-turns, and thus the magnetic force of the two coils, become the same.

Fig. 8 (above, right)—Typical time graph of current-potential overbalance protection as applied to a system of several stations in series.

Fig. 9 (below, right)—Time graph of current-potential overbalance protection of 30-cycle system.

would be possible. In order to be sure that the protection of switch *A*, Fig. 7, will be effective for shorts at the end of the line and for troubles in the substation, it will be necessary to set the relay balance of potential and current somewhat higher than the impedance would require, say 12 per cent voltage per normal load current, instead of 10 per cent voltage per normal load current, as was assumed in Fig. 7. Thus, in case a substation bus short creates on the relay 10 per cent voltage per normal load current only, the current coil will have a decided overpowering effect and balance to be effective for line end shorts and substation shorts. This set is provided with a time delay sufficient to allow switch *B* to clear on instantaneous protection. The other set of protection is adjusted for a balance which will confine its active range to its own line. This set can be made instantaneous since its balance adjustment prevents it from operating in case of a short circuit beyond switch *B*, so that no time-selective adjustment will be required for this set.

The functioning and radius of action of a protection as above described for a system of two lines in series

is illustrated in Fig. 8. Distant line shorts on line $A$, as well as line $B$, are cleared by their respective switches by time-limit relays. Short circuits at the beginning of the respective lines are cleared by instantaneous relays. From this example it will be noticed that the great advantage of the new scheme is that no progressive time setting toward the power house is required, such as is necessary with the excess-current principle of protection; but that instantaneous protection can be introduced by applying relays of such a potential current balance setting that their range of action does not overlap the switch ahead.

In the spring of 1920 the first lines were equipped with this new type of protection. The protection was tested out with actual extreme conditions, and the result proved fully satisfactory. It was, therefore, decided to equip the whole system with this new type of protection. The 50,000-volt line system has been completed and in service since the fall of 1921, and the power house protection is in the course of completion. Fig. 9 shows a diagram of the system, indicating in what time short circuits at various points of the system are cleared. From this diagram it will be noticed that the action of the relay depends entirely on the location of the short circuit, the protection being equally effective for both minimum and maximum generator capacity. The diagram shows how distant line shorts only are cleared by time protection, whereas shorts nearer the substations are all cleared instantaneously.

In the fall of 1921, after completion of the line protection a series of tests were made to find out any possible weak feature of the new protection, and the tests proved that the protection was fully effective for all conceivable conditions.

The protection has effectively operated ever since its installation. The outstanding features with respect to the operating results are:

1. Since the installation of the new protection there has been no case where the operator had to clear a short-circuited line by hand, a condition which was quite a common occurrence with the previous excess-current protection.

2. There is nothing to indicate that the new principle might cause incorrect actions.

3. The one inconvenient feature of the protection wherever the protection has to be effective even for currents below normal load current is the danger that the relay is liable to trip a line on normal load current should ever the potential circuit be ruptured accidentally. During the two years of service there have been two such cases recorded. Both these cases were caused by an open circuit developing in the tap block of relays. Some alteration in the design, however, has prevented any recurrence. Other causes of open circuiting the potential circuits are very remote as long as the wiring layout is carefully worked out and as long as the operating staff is properly instructed.

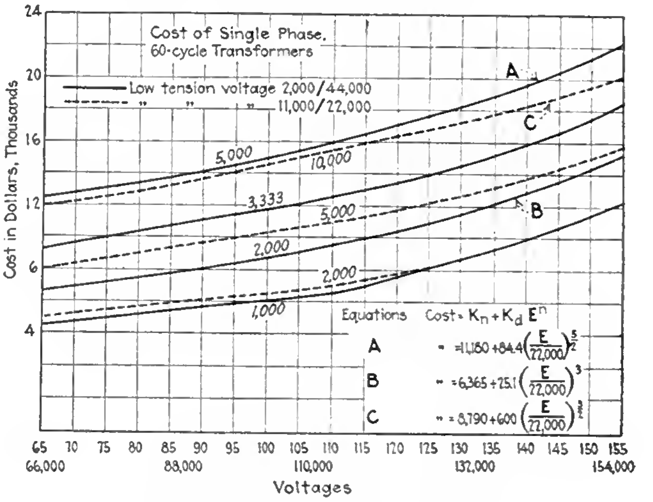
Similar conditions exist on all systems where the total power-house capacity is fed over a few large-capacity trunk lines. In any such case the sustained short-circuit current for distant shorts will always drop near or below the maximum normal load current, so that any excess current relay, set at 150 per cent of normal load current, will become useless. This condition is still more pronounced on modern systems, where the tendency is to install high-reactance generators which have a sustained short-circuit current of normal load current or less.

# The Economical Design of Transmission Systems

## The Determination of the Most Economical Design for Backbone Lines Requires the Exercise of Judgment and Many Data

BY P. O. REYNEAU AND H. P. SEELYE

ANY problem of transmission design is one which will bear an almost infinite amount of study. Naturally the detail to which such a study should be carried will depend somewhat on the size and nature of the project. As a rule, however, time spent on an economical determination is well repaid. In many cases some of the variables are limited—voltage may be determined by other than economical considerations, route and location for towers may be fixed, and so on. This simplifies the problem, but in any case some study is essential to an accurate determination. Variations in the details will, of course, be found to accommodate special conditions. In any case it is to be emphasized that the problem is a complicated one and usually does not admit of solution by any easy, approximate method.



A CONVENIENT FORM ON WHICH TO KEEP COSTS OF SINGLE-PHASE TRANSFORMERS

In order to systematize the computations and to facilitate the determination of the effect of changes or additions to any design on the total cost the following factors should be considered:

1. *Fixed Quantities.*—As many as possible of the elements affecting the problem should be fixed. These will be:

(a) The maximum load. The expected increase should also be determined, and in case of more than one feeding point each load must be considered separately.
(b) The load factor and equivalent hours of the load.
(c) The power factor of load.
(d) The cost of energy per kilowatt-hour.
(e) The length and cost of right-of-way (at least approximately) for the various possible routes.
(f) The type of tower to be used for each route.
(g) The percentage of annual charges applicable to the various kinds of property entering into a transmission line.

2. *Limits of Problem.*—It is essential to discover approximately the limits of the problem so that time will not be wasted in considering voltages and wire sizes which are far from the final result. In case the designer's experience is not sufficient to tell him this, approximate formulas will be found useful.

3. *Cost Data.*—The necessary cost data, quotations, etc., must be collected. These will be:

(a) Cost of transformers, of the size determined by the load for various voltages within the range of the problem (more than one size may be necessary, especially if there

are several feeding points with different sized loads). Core loss and copper loss should also be ascertained.

(b) Cost of switches of proper size for various voltages.

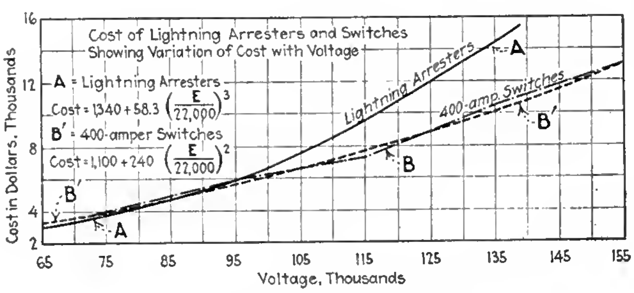
(c) Cost of lightning arresters for various voltages.

(d) Cost of insulators for various voltages. The limit in mechanical load for any string of insulators should also be determined. In cases where pin insulators are considered in comparison with suspension type, the cost of both must be obtained. The cost of placing insulators should be included.

(e) The cost per pound of conductors of different materials—copper, copper-clad steel and aluminum steel. In case the price per pound varies considerably with the size, the cost for a variety of sizes within the range of the problem should be obtained. The cost of stringing the conductor should be estimated or determined from previous experience.

(f) The cost of various sizes of tower for each type. If possible, sufficient costs on towers should be obtained to enable the variation of cost with span, wire size and voltage to be determined. This could be accomplished if three voltages, three wire sizes and three different spans covering the probable range of the problem were considered. By plotting curves the intermediate values could be determined with sufficient accuracy. The cost of foundation should be included with each tower. Anchor towers and semi-anchor towers should also be considered and similar costs obtained.

(g) The cost of terminal substations of the required size. The variation in this cost with voltage should be



CURVES LIKE THIS FACILITATE COMPARISONS

determined if possible. In case other special terminal apparatus, such as condensers or regulators, are considered, the additional substation cost for these must be estimated.

(h) Quotations on special apparatus considered, regulators, condensers, etc., should be obtained with variations in this cost with size and voltage.

(i) Annual cost of maintenance, testing, patroling, etc., must be estimated.

4. *Arrangement of Cost Data.*—After the data are collected they should be arranged for convenient use. This probably can best be done by means of curves. Such curves are illustrated in the accompanying figures. They should give:

(a) Annual cost of transformers (in place) in terms of voltage.

(b) Annual cost of switches (in place) in terms of voltage.

(c) Annual cost of lightning arresters (in place) in terms of voltage.

(d) Annual cost of insulators per string in terms of voltage.

(e) Annual cost per mile of conductors of different materials in place in terms of cross-sectional area.

(f) Annual cost of towers in place. These can be arranged, for example, as a series of curves for each standard voltages, showing for each standard wire size and material the variation of cost with span.

(g) Annual cost on terminal substation in terms of voltage.

(h) Annual cost of transformer energy losses in terms of voltage.

(i) Annual cost of line energy losses per mile for each material of conductor considered in terms of cross-sectional area.

5. *Most Economical Design.*— It now remains to apply these costs to determining the most economical design. The route is usually the most limited of all the variables, there ordinarily being no more than two or three possible routes at most. Likewise, on any route the layout is somewhat limited. Locations of anchor towers and semi-anchor towers are usually more or less fixed. On straight runs the span can often be varied. If two or three possible layouts are made for each route, varying the span where possible, a sufficient comparison will be obtained.

If, now, for each of these layouts a sheet of curves is prepared showing, for each standard conductor considered, a curve giving the variation in total annual cost with the voltage, a complete and accurate study of the economy may be made. Not only will the most economical voltage, wire size, route and layout be obtained but the comparative effect of variation in these quantities may be studied. Curves may be added to show comparison of two or more circuits with a single circuit. If a design chosen tentatively proves on further investigation to be impracticable on account of corona limit, too great regulation, etc., the cost of correcting the fault by a change in design, addition of regulator or in some similar way, as compared with one of the other designs not having that fault, may be easily determined.

## Fewer Pounds of Coal per Kilowatt-Hour

SOME interesting studies have been made by A. H. Horton, chief of the Power Resources Branch, United States Geological Survey, of the reports of production of electricity and consumption of fuel by public utility plants which are received by that government bureau. The gradual decrease within the last few years in the rate of consumption of coal per kilowatt-hour of electricity generated by public utility power plants is a remarkable achievement, the importance of which is very readily recognized when it is considered that 10,575,000 tons more of coal and its equivalent in other fuels would have been consumed in generating the electricity produced in 1922 by the use of fuel if the rate of consumption of fuel per kilowatt-hour had been as high as that of 1919. This gain in efficiency represents a saving of approximately $50,000,000.

A comparison of the percentage change in output by the use of fuel from one year to another with the percentage change in the consumption of coal for the same years indicates a marked advance in economy and utilization of fuel. For instance, the output by the use of fuel was 17 per cent greater in 1922 than in 1921, but the increase in coal consumption was only 8.2 per cent, or less than half the increase in output. The remarkable gain in efficiency and utilization of fuel and in plant operation is clearly shown by considering the average fuel consumption per kilowatt-hour for each of the four years, that is from 1919 to 1922. This average is most satisfactorily determined by converting the oil and gas consumed to their equivalent in coal. Records of actual operation indicate that a ton of coal is equivalent to about four barrels of oil and about 35,000 cu.ft. of gas. These figures will, of course, vary with the relative efficiency in utilizing the three fuels, especially coal, the methods of using which are the most susceptible to improvement. The accompanying table indicates most thoroughly the increased efficiency which has been obtained in public utility electric generating plants during the last four years.

AVERAGE CONSUMPTION OF COAL PER KILOWATT-HOUR BY PUBLIC UTILITY POWER PLANTS IN THE UNITED STATES, 1919 TO 1922

| Year | Output with the Use of Fuel* (Kw.-hr.) | Net Tons | Consumption of Coal and Its Equivalent in Other Fuels† Pounds per Kw.-hr. | Percentage of 1919 Rate |
|---|---|---|---|---|
| 1919 | 24,176,000,000 | 38,784,000 | 3.22 | 100.0 |
| 1920 | 27,248,000,000 | 41,424,000 | 3.04 | 94.4 |
| 1921 | 25,863,000,000 | 35,236,000 | 2.73 | 84.8 |
| 1922 | 30,215,000,000 | 37,996,000 | 2.52 | 78.3 |

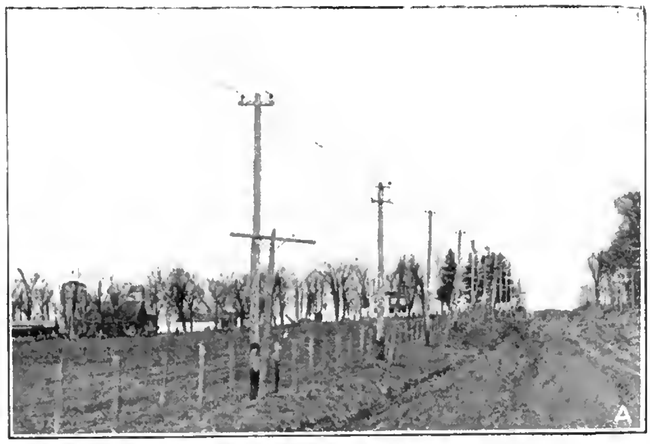
* Coal, oil, and gas. † 1 ton coal = 4 bbl. oil = 35,000 cu.ft. of gas.

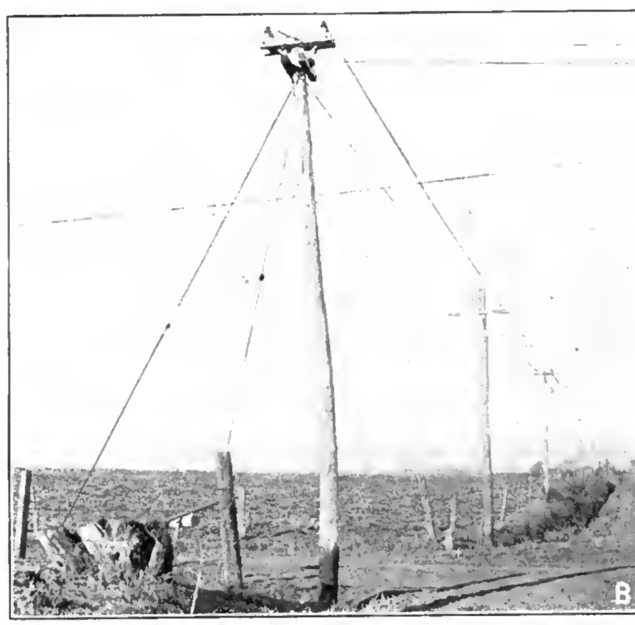
# Some Iowa Rural-Line Practices

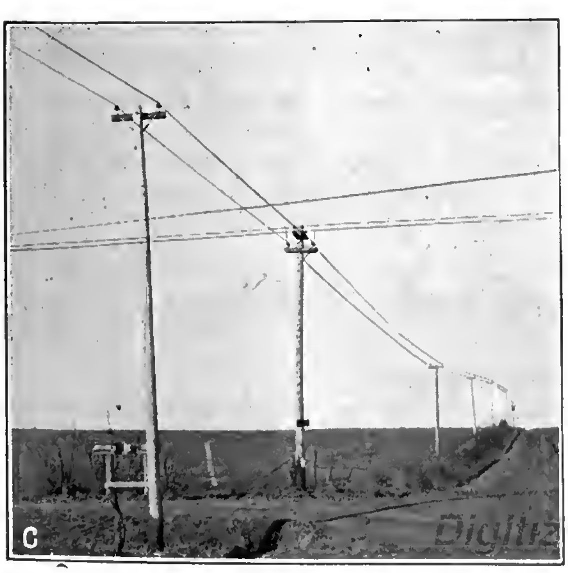
South Fairfax Line Constructed Under Iowa Commission Specifications — Construction Features and Load Characteristics —Utility to Maintain Line at Expense of Farm-Line Company

THE construction and operation of rural lines has seemed, in common opinion, to involve something special in the way of construction, maintenance methods and operating arrangements. In the sense that there is more territory to be covered, and therefore more expense involved, it may be necessary to adopt maintenance and operating methods slightly different from those in city or town territory. Such matters as meter reading may be done by means of cards on which the consumer marks the position of the meter dial hands at the billing period and then drops the cards into the mail so that the utility company may "read" the meters and render the bill. In such cases it is customary once or twice a year to make check readings, the work being done by a utility employee. This is to insure that no errors creep in and continue from year to year, leading to a reckoning at some future time that might be embarrassing to every one concerned. Operating matters such as trouble shooting, repairs due to accidents, action of the elements or emergency troubles of any kind are sometimes taken care of by arrangement with some local electrical contractor who works with the central station on such matters and who is on call for emergency purposes. Such arrangements are usually on a contract basis. In heavy maintenance work this arrangement is sometimes used, and in other cases the work is taken care of by the regular maintenance crews of the central-station company.

Just how such matters are best cared for depends on the individual central-station situation. In the case of







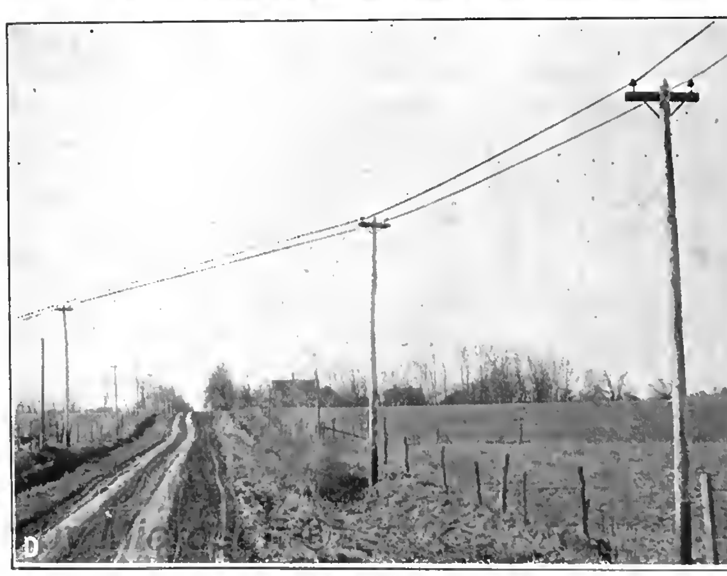


FIG. 1—CHARACTER OF LINE CONSTRUCTION EMPLOYED ON THE RURAL LINES BELONGING TO THE SOUTH FAIRFAX ELECTRIC COMPANY AND SUPPLIED FROM THE SYSTEM OF THE IOWA RAILWAY & LIGHT COMPANY

A—Straight-line construction on which two-pin cross-arms are used to carry the 6,600-volt, single-phase circuits. B—Typical corner construction. C—Typical crossroads construction with lines branching both ways. D—Cross-over construction necessitated by location of telephone circuits on the highway.

a company with a well-organized operating force, a fairly large number of centers from which the various crews work and distances to travel that are not too great, the work is usually best done by these forces, including even the meter reading. In other cases arrangements with local agencies that can be depended on seem to be best.

What shall be done in any particular case will depend on the local situation, the availability of organized utility crews at convenient points or the availability of other agencies that can be depended on to carry out the work properly. In short, the problem is economic in character, and its solution must depend on the distinctive factors present in each case.

Iowa probably contains as many rural lines as any state in the Union. This is due to the extent of its agricultural areas. A good example of the present rural-line practice of the Iowa Railway & Light Company is the 6,600-volt, single-phase, 60-cycle line south of Fairfax, which was built about three years ago. Thirty farmers raised slightly more than $5,000 to build the eleven miles of line, to which they added a considerable amount of labor contributed by the farmers themselves. The line was built by a utility employee loaned for the purpose. In the contract with the utility for wholesale power it is specified that the local company, the South Fairfax Electric Company, shall follow the specifications drawn for such lines by the Iowa Board of Railroad Commissioners. These specifications are practically identical with those in the report of the Overhead-Systems Committee of the National Electric Light Association presented at the 1922 convention. The National Electrical Safety Code is the basis of the requirements, and the aim is to insure substantial construction—construction that in maintenance and operation results will compare with construction in ordinary distribution practice.

The aim is to prevent the construction on the public highways (a) of lines which will fail within a few years and require rebuilding at a high expense because flimsy construction was used in the beginning, (b) of lines which will require very high expense for maintenance after a few years for the same reason, and (c) of lines which will become a menace, because of their physical condition, to the public and to other utilities occupying the same highway. There is no departure from well-established distribution practice, as will be seen from examination of the photographs of the completed lines. The lines are maintained under a contract by the Iowa Railway & Light Company, and the cost of maintenance is charged to the South Fairfax Electric Company. As the situation has actually worked out there has so far been no real maintenance work required as the lines are not old enough to require repairs except those due to accident or storms. For fuse replacements and minor troubles there is always available among the group of farmers some one who has learned to take care of such troubles.

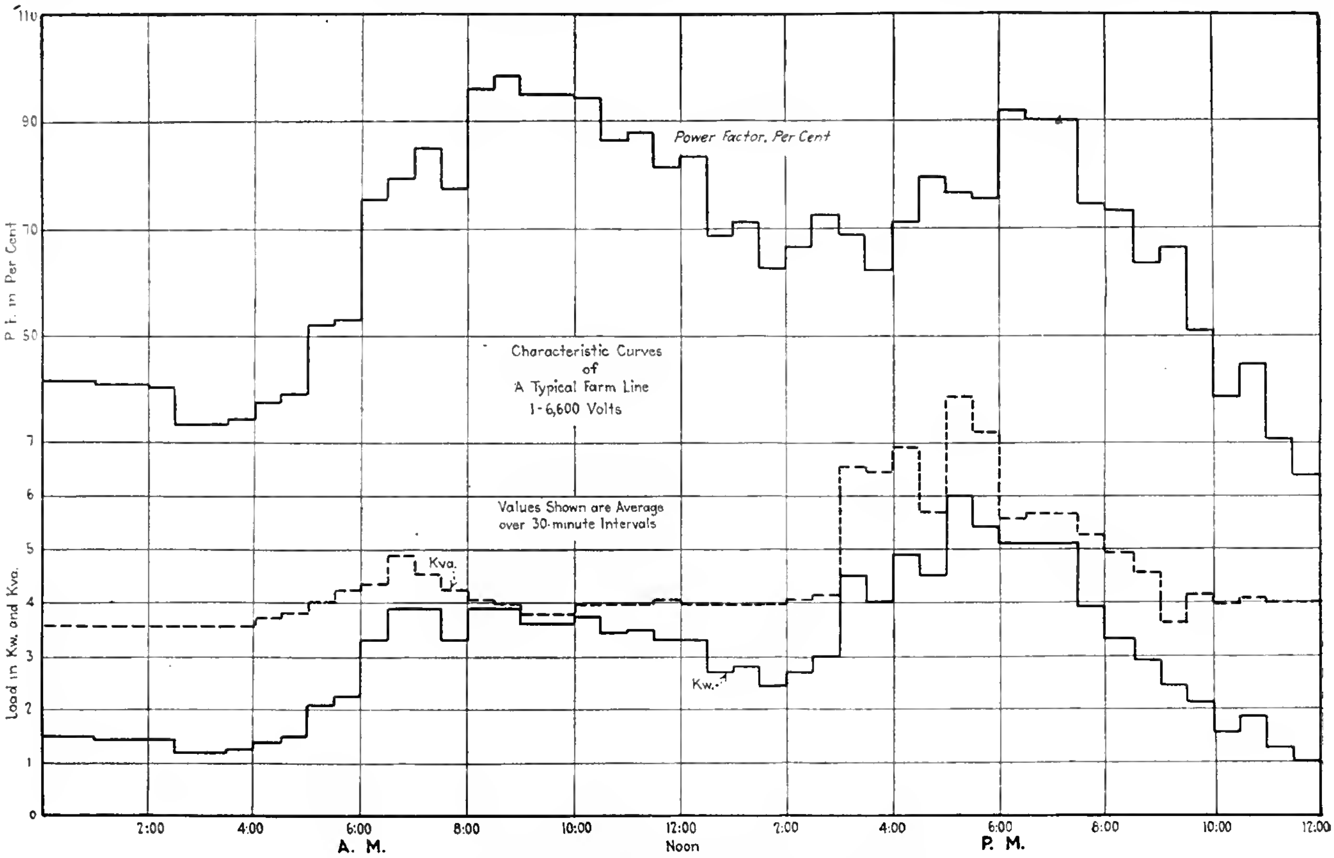

FIG. 2—POWER-FACTOR LOAD AT SOUTH FAIRFAX

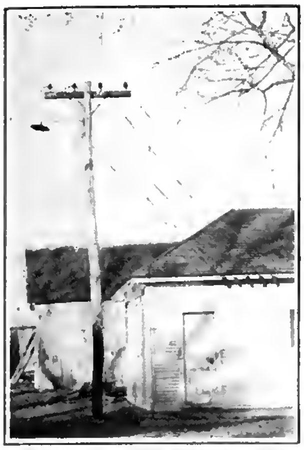
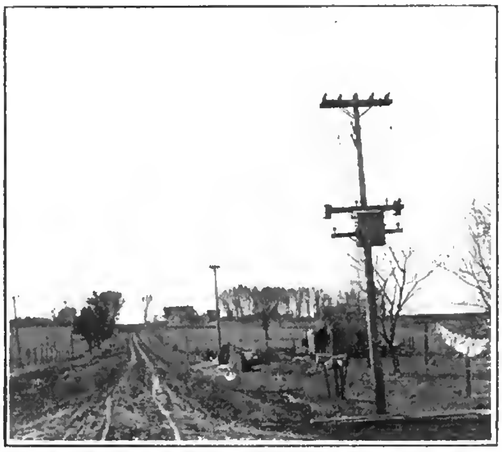
Much has been said about the poor characteristics of rural-line loads. This typical curve shows that there are times in the day when the power factor is on a fairly satisfactory basis. The middle of the day and the late night and early morning hours give the worst power-factor conditions. There should also be no objection to the power load here shown.

### CONSTRUCTION FEATURES OF THE LINES

Fig. 1 shows several views of the 6,600-volt, single-phase, straight-line construction and the corners. A is a section along the highway in which a transposition is placed. The poles are 25 ft. high except at the highway crossings or other points where greater clearance is needed and where 30-ft. poles are used. Minimum top





FIGS. 3, 4 AND 5—YARD LIGHTING ON A FARM, SECTION SWITCH INSTALLATION AND MASTER METER EQUIPMENT AT FAIRFAX

Fig. 3—This illustrates the terminal pole for the service which is employed for the yard lighting also. The meters are in the small building at the right of the pole.

Fig. 4—Plain underhung disconnecting switches for 6,600-volt sectionizing pole.

Fig. 5—The farmers buy power wholesale and then retail it to the members of the South Fairfax Electric Company. The farmers read their own meters and transmit the readings to the secretary, who sends separate bills to all of the individual consumers each month.

diameters of 6 in. are adopted. All poles are butt-treated Western red cedar. The line cross-arms are two-pin, while four-pin arms are used at points where special construction requires more pin space. The standard N. E. L. A. specification is followed in the use of cross-arms, a 3¼-in. x 4¼-in. cross-section being employed. Cross-arm braces are 26 in., and the bolts used except on the braces are ⅝ in. No attempt is made to use special hardware. B shows the corner construction and the guying practice followed on the entire line. C shows a corner at a crossroads point where the line branches in both directions. D shows a point where it has been necessary to jog across the highway because of the presence of telephone-line construction.

Fig. 4 shows section switches which are used on the line and the method of mounting. These are plain underhung disconnecting switches for 6,600-volt service.

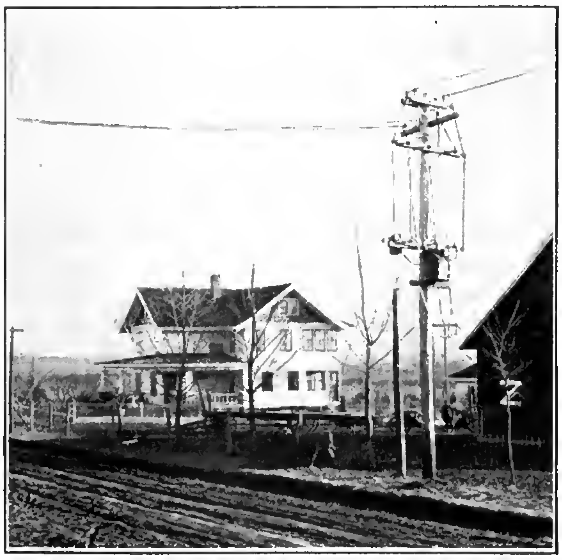
Fig. 6 shows a transformer mounting that is somewhat unusual in that it is of 10-kva. capacity and the meter is mounted on the pole. The farm is that of Cyrus Tow, a well-known cattle fancier, who makes a rather larger use of electricity than the average farmer. Feed grinding and water pumping as well as lighting all over the farm call for fairly large amounts of electrical energy.

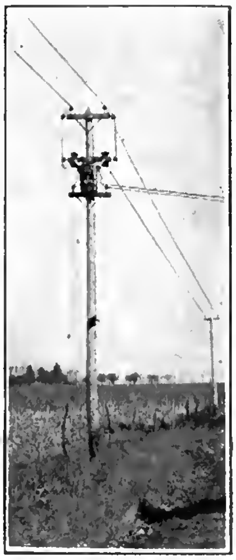
Figs. 7 and 8 show typical transformer mountings on the rest of the line. Fig. 7 is at the end of the present line and serves two consumers. Fig. 8 is erected on the highway and shows the service tap-off clearly. Consumers are so far apart that in most instances each consumer has his own equipment, because secondaries would be too long to reach more than one individual from a transformer.

Fig. 3 shows the way in which the farmers make use of light in their yards. In this case the end of the service line and also a yard lighting installation are represented. The meter installation is in the small building to which the service lines drop.

Typical meter installations are shown in Figs. 9 and 10. Fig. 9 is typical for places having a single meter. Fig. 10 is one case in which both power and lighting meters are employed. It is interesting to note that the farmers themselves hung at least a part of the meters.

Fig. 5 is the master-meter installation at the begin-





FIGS 6, 7 AND 8—TYPICAL TRANSFORMER INSTALLATION ON RURAL LINES

Fig. 6—A transformer installation with the meter on the pole. This 10-kw. installation is at a well-known cattle-raising farm, where a rather unusual amount of power is used. Most of the farms use transformers rated at 1½ kw.

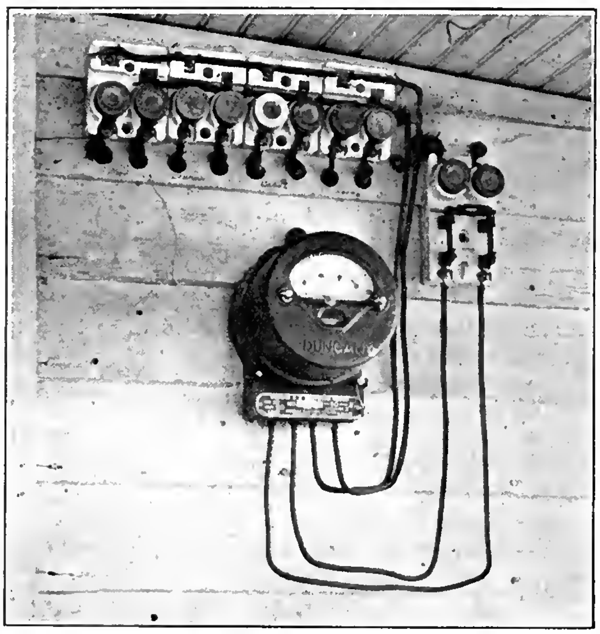
Fig. 7—Transformer installation located at the end of the line and serving two customers.

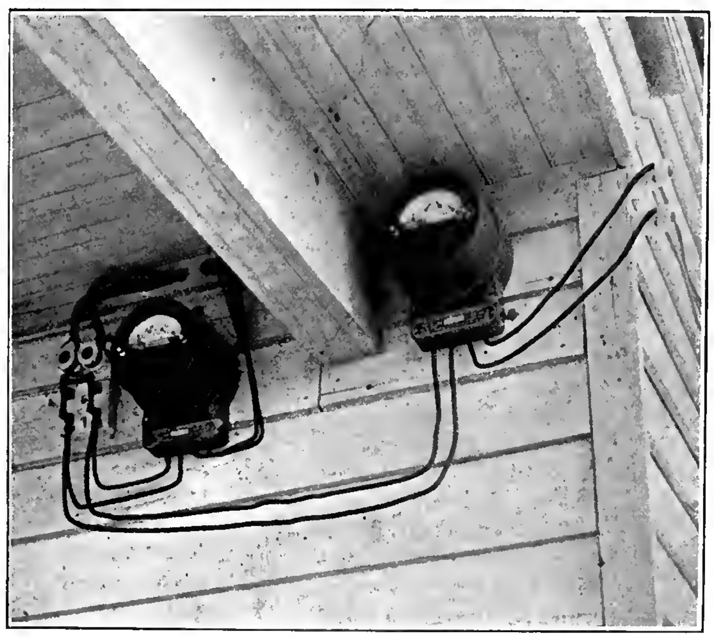
Fig. 8—The majority of services are of the nature shown here, where a single customer is served from each transformer.

ning of the line out of Fairfax. Since this photograph was made the meter has been placed in another box near the foot of the pole, only the transformers being left in the upper box. Energy is sold wholesale to the corporation and each farmer reads his own meter. These readings are sent to the secretary of the company, who handles the billing that divides the expense of energy, maintenance and other expenses between the farmers getting service. The rate to the South Fairfax Electric Company is made up of a monthly demand charge of $5 per kva. plus a service charge of $5 per month. An energy rate of 2½ cents is charged for the consumption shown by the master meter. On Jan. 1 and July 1 a 1-mill adjustment plus or minus is made on the energy rate for each 30-cent variation above or below $5.50 per ton taken as the average cost of coal for the previous six-month period. The monthly demand is taken as the highest average kilovolt-ampere load recorded in a fifteen-minute period, provided this figure be not less than 75 per cent of the highest maximum for the preceding twelve months, in which event it shall be 75 per cent of the preceding twelve months period.

Some studies have been made on this line to determine the characteristics of the load. Fig. 2 shows the results of the study in the form of a typical daily load curve giving the kilowatt load, the kilovolt-ampere load corresponding to the kilowatt load, and the power factor for the different hours of the day. The interesting curve is that showing power factor. Contrary to the usual assumption, there are hours of the day when the power factor on the line is on a good basis. Twice a day it rises to 90 per cent or better. During the middle of the day it drops to less than 70 per cent, and during the late night and early morning hours it falls far below 50 per cent.

This sort of study is being carried out regularly by the engineering school at the Iowa State College at Ames. These studies are expected to continue for several years, or at least until reliable data on the characteristics of rural-line loads are established.





FIGS. 9 AND 10—METER INSTALLATIONS AT CONSUMER'S PREMISES

Fig. 9—This represents a lighting and small power installation. The farmers have made some of these installations themselves.

Fig. 10—Where considerable power is used the consumer employs a power meter in addition to that for lighting.

## Putting a Tangible Value on Diversity Factor

THE value of diversity factor between classes of service in the economical production and distribution of electrical energy was very clearly explained in a recent address by Samuel Insull before the Western Society of Engineers. He pointed out that with the existing street-railway and light and power load in Chicago the combined maximum demand if all steam railroads entering Chicago were electrified at their terminals would be 1,110,500 kw.—that is, if the separate demands were added together. In 1922 about twice as much power was required to supply light and power for Chicago as it took to supply the street railways, and if the steam railroads had been electrified they also would have required about one-half the power now used for light and power. Still, if all of these loads had been served from one electric system, as is now being done so far as the street railways and light and power are concerned, the coincident demand would be only 959,500 kw. as compared with the combined maximum demand of 1,110,500 kw., making a diversity of 151,000 kw. between the various classes of load.

Mr. Insull went on to say: "If you will take that saving of 151,000 kw. and figure it out at $100 per kilowatt, which is a very low price for central stations at this time, and allow a 25 per cent reserve, that diversity would save an investment of $18,120,000. And if you go a little further and include the diversity that exists between the city and county districts, the diversity is increased to about 170,000 kw. The saving in serving all these various organizations, with energy produced from the same source, would be upward of $20,000,000, not figuring anything for the electrification of the steam railroads outside the switching area."

The foregoing saving is not based on the diversity between the demands of individual consumers, but, as pointed out by Mr. Insull, on the diversity between the major classes of service.

# The Preference of Preferred Stocks

## Remarkable Record of the Junior Securities of Electric Light and Power Companies in Earning Power and in Popularity—Customer Ownership a New Factor

By VAN H. CARTMELL
*Bonbright & Company, Inc., Investment Bankers, New York*

ONE of the outstanding features of the trend of financial affairs in 1922 was the rise in popularity of preferred stocks. This was the perfectly natural outcome of a sequence of investment conditions which had its beginning in the period of inflation subsequent to the chaotic markets of the war. At that time high money rates prevailed, and new bond issues commonly bore coupons at 7 and 8 per cent. The reconstruction of industry, furthermore, demanded large capital, and these bonds and similarly high-interest-bearing notes were issued in considerable volume. As money rates eased and as industry gradually began its return to a state nearer "normalcy" such companies as were the first to rehabilitate themselves began calling their high-interest-bearing bonds. By the beginning of 1922 conditions were sufficiently better to occasion a very general reduction of these high-coupon issues. During the year a great many of the 7 and 8 per cent bonds and notes were retired by the companies that issued them during the stress of the previous competition for capital. Refunding issues commonly bore considerably lower coupons, and the general average of bond prices was correspondingly higher.

For two or three years, however, the investor had been receiving not only a high ultimate yield on his investment, but had been securing an annual return of 7 per cent or better with a very fair security. It was a perfectly natural reaction for him to look about for a means of reinvesting his money to similar advantage. There followed a period characterized by an assiduous hunting out of laggards in the bond market. The stragglers behind the general up trend of bond prices were one by one brought up to the procession by individual investors who still sought a 7 per cent return.

Very naturally the time came when the great bulk of well-secured bonds were selling consistently at a rate to yield less than 7 per cent and bonds with 7 per cent or higher coupons were very rare indeed.

It was then that the investor, influenced by the rich yields of his investments during recent years, sought another class of investment in which he might with a certain sense of safety still obtain a generous return on his capital. This opportunity was immediately presented by the broad field of preferred stocks.

### Opportunity Offered by Preferred Stocks

Preferred stocks had for a period been rather overlooked in the market. There was small inducement to invest in this class of securities when bonds were yielding a high rate and the speculative possibilities of common stocks were enormous. Suddenly, however, they became strikingly attractive. The inattention that had been theirs during the early part of the reconstruction period had left them relatively far behind the procession of advancing values. The gradual betterment of the companies behind them at the same time made their investment position correspondingly better. Almost overnight came a sudden realization of the peculiar advantages of their situation. No issues of preferred stock were in a better position to attract investors than those of public utility companies, and more particularly those of electric light and power companies. Examination of the record of a few of these securities brought out their unusually strong investment foundation in an extremely vivid manner.

Many began to appreciate rapidly in price, and a report on public utility preferred stocks more exhaustive than any available seemed worth preparing. A thorough investigation of their record over a protracted period was made by George J. Wightman. The results are certainly worthy of a good deal of thought.

The most significant portion of this careful analysis was that covering the preferred stocks of the prominent electric power and light companies. The dividend record of every power and light company in the United States whose output exceeded 100,000,000 kw.-hr. per year, as well as that of all the larger holding companies in which traction operation had not been an important element and any of whose subsidiaries supplied power and light to cities with more than 100,000 population, was carefully checked. This list included practically all electric light and power companies with gross earnings of $3,000,000 and upward. The combined capitalization represented more than 85 per cent of the total capitalization of all the electric light and power companies in the United States.

### The Remarkable Record

This list included eighty-one companies, sixty-seven of which had preferred stocks. In the case of the fourteen with only common stock outstanding the records were investigated and included in the results. The conclusions obtained through this analysis are indeed striking. It shows that:

1. Current cash dividends are being paid on all the issues in question.
2. In only three cases are there accumulated back dividends unpaid.
3. In thirteen other cases dividends have been deferred but have subsequently been paid off in stock or in cash.
4. In all other cases the stocks have unbroken dividend records.

In more detail, and distinguishing between the companies having preferred stock issues and those with simply one capital stock outstanding, the results of the analysis follow:

Of the sixty-seven companies having preferred stocks:

Fifty-one companies have never omitted a preferred dividend since such stocks were issued. The majority of these have been outstanding for ten years or more.

Thirteen companies had accumulations—now paid off in stock, cash or both. (Many of the companies included in this analysis conduct some traction operation in addition to their electric power and light business. The contributing causes of these deferments seem to have been about equally divided between the high cost in recent years of such traction operation and the heavy expense incurred in initiating hydro-electric enterprises.)

# Dividend Record of Electric Light and Power Companies

PREFERRED STOCK

| Company | Incorporated | Dividend Record |
|---|---|---|
| Adirondack Power & Light Corp. | Mar., 1920 | 7 per cent preferred annually July, 1920, to date—8 per cent preferred annually July, 1921, to date. |
| Alabama Power Co. | Dec., 1906 | 7 per cent annually from issuance 1920 to date. |
| American Gas & Electric Co. | Dec., 1906 | 6 per cent annually 1907 to date. |
| American Light & Traction Co. | May, 1901 | 6 per cent annually 1901 to date. |
| American Power & Light Co. | Sept., 1909 | 6 per cent annually 1910 to date. |
| Appalachian Power Co. | May, 1911 | First preferred 7 per cent annually from issuance March, 1920, to date.* |
| California Oregon Power Co. | Oct., 1920 | 7 per cent annually from issuance October, 1921, to date. |
| Carolina Power & Light Co. | July, 1908 | 6 per cent July, 1909, to January, 1911—7 per cent annually January, 1911, to date. |
| Central Illinois Public Service Co. | May, 1902 | 6 per cent annually 1912 to date. |
| Cleveland Electric Illuminating Co. | In 1892 | 6 per cent preferred annually 1893 to date—8 per cent preferred annually from issuance September, 1920, to date. |
| Colorado Power Co. | Apr., 1913 | 7 per cent annually 1913 to date. |
| Columbus Railway, Power & Light Co. | Nov., 1913 | 5 per cent preferred from 1914 to date—6 per cent preferred from 1914 to date.† |
| Connecticut Light & Power Co. | Aug., 1917 | 8 per cent annually from issuance December, 1921, to date. |
| Consolidated Gas, Electric Light & Power of Baltimore | June, 1906 | 6 per cent 1906 to 1917 when retired—new 7 per cent and 8 per cent issued 1922—common paid not less than 5 per cent since 1911. |
| Consumers Power Co. of Michigan | Apr., 1910 | 6 per cent preferred annually 1910 to date—7 per cent preferred from issuance September, 1920, to date. |
| Dayton Power & Light Co. | Mar., 1911 | 6 per cent annually 1911 to date. |
| Duquesne Light Co. | Aug., 1903 | 7 per cent annually from issuance in 1915 to date. |
| Electric Bond & Share Co. | Feb., 1905 | Dividends of 5 per cent annually 1905 to 1911—6 per cent 1911 to date. |
| Empire District Electric Co. | Oct., 1909 | 6 per cent from 1909 to date—accumulated unpaid dividends paid up by 1918. |
| Fort Worth Power & Light Co. | July, 1911 | 7 per cent annually 1911 to date. |
| Georgia Railway & Power Co. | Oct., 1911 | Cumulative at 6 per cent from 1912—a new issue of 8 per cent preferred was brought out in 1922 to care for unpaid dividends amounting to 30½ per cent. |
| Idaho Power Co. | May, 1915 | 7 per cent annually 1916 to date. |
| Indiana & Michigan Electric Co. | May, 1907 | 7 per cent annually from issuance in 1920 to date. |
| Kansas City Power & Light Co. | June, 1919 | $7 annually February, 1921, to date. |
| Kansas Gas & Electric Co. | Dec., 1909 | 7 per cent annually 1910 to date. |
| Louisville Gas & Electric Co. | Feb., 1913 | 6 per cent annually 1913 to date. |
| Metropolitan Edison Co. | Aug., 1917 | $7 annually from issuance October, 1919, to date. |
| Milwaukee Electric Railway & Light Co. | Jan., 1896 | 6 per cent annually 1900 to date. |
| Mississippi River Power Co. | Aug., 1910 | 6 per cent—accumulation amounting to 37½ per cent from 1915 paid off in stock March, 1921—cash dividends began April 1, 1921. |
| Montana Power Co. | Dec., 1912 | 7 per cent annually 1913 to date. |
| Nebraska Power Co. | Apr., 1917 | 7 per cent annually 1917 to date. |
| Nevada-California Electric Corp. | Dec., 1914 | Not less than 4 per cent 1915 to October, 1918—none to January, 1923, when resumed at 7 per cent. |
| New England Power Co. | In 1911 | 6 per cent annually 1912 to date. |
| Niagara Falls Power Co. | In 1886 | 7 per cent annually 1919 to date. |
| Niagara, Lockport & Ontario Power Co. | May, 1894 | 6 per cent annually 1912 to December, 1920—stock since exchanged for common shares—new 7 per cent preferred issued November, 1922. |
| North American Co. | June, 1890 | 6 per cent annually from issuance July, 1921—common has paid not less than 3¾ per cent from 1903 to date, except 1908, when no dividend was paid. |
| Northern Ohio Traction & Light Co. | Nov., 1902 | 6 per cent preferred annually 1911 to date—7 per cent preferred from issuance May, 1921, to date. |
| Northern States Power Co. | Dec., 1909 | 7 per cent annually 1910 to date. |
| Northwestern Electric Co. | In 1911 | 6 per cent preferred annually 1914 to date—7 per cent preferred annually from issuance August, 1921, to date. |
| Northwestern Power Co. | Jan., 1905 | 6 per cent—cumulative from 1909—accumulated unpaid dividends taken up in 1914 by stock dividend and in 1922 by exchange into American Power & Light Co. preferred—on a cash basis since January, 1921. |
| Ohio Power Co. | Apr., 1907 | 6 per cent annually 1907 to date. |
| Pacific Gas & Electric Co. | Oct., 1905 | 6 per cent annually 1906 to date—three years' accumulation paid off in stock 1909. |
| Pennsylvania-Ohio Power & Light Co. | Oct., 1920 | 8 per cent annually from November, 1920, to date. |
| Pennsylvania Power & Light Co. | June, 1920 | $7 annually July, 1920, to date. |
| Philadelphia Electric Co. | Oct., 1902 | 8 per cent annually from issuance in September, 1920, to date. |
| Portland Railway, Light & Power Co. | June, 1906 | Old preferred 5 per cent annually 1906 to retirement in 1910—new 6 per cent preferred from 1915 to date—accumulated unpaid dividends paid off in cash and stock 1921—7 per cent preferred annually from issuance January, 1922, to date. |
| Public Service Corp. of New Jersey | May, 1903 | 8 per cent annually from issuance February, 1919, to date. |
| Puget Sound Power & Light Co. | Jan., 1912 | 6 per cent from 1912 to date—accumulated unpaid dividends of 22½ per cent paid off in stock and cash 1922—7 per cent preferred annually from issuance January, 1922, to date. |
| Rochester Gas & Electric Co. | June, 1904 | 5 per cent preferred annually 1904 to date—7 per cent preferred from issuance March, 1918.‡ |
| San Joaquin Light & Power Corp. | July, 1910 | 6 per cent preferred annually 1912 to 1914, and from 1917 to date—accumulated dividends unpaid amount to 16½ per cent —7 per cent preferred annually from issuance September, 1920, to date. |
| Scranton Electric Co. | Apr., 1907 | 6 per cent annually 107 to date. |
| Southern California Edison Co. | July, 1909 | 5 per cent annually 1909 to 1914—6 per cent 1914 to 1916—7 per cent 1916 to 1921—8 per cent 1921 to date. |
| Southern Power Co. | June, 1905 | 7 per cent annually accumulated unpaid dividends have been taken care of. |
| Southwestern Power & Light Co. | July, 1912 | 7 per cent annually 1912 to date. |
| Standard Gas & Electric Co. | Apr., 1910 | 7 per cent 1910 to 1912—8 per cent 1912 to date—13 per cent accumulation paid off in stock, 1919. |
| Syracuse Lighting Co. | May, 1901 | Not less than 5 per cent annually since 1901—8 per cent 1915 to date. |
| Tennessee Electric Power Co. | June, 1922 | 6 per cent and 7 per cent first preferred from issuance July, 1922, to date. |
| Texas Power & Light Co. | May, 1912 | 7 per cent annually 1912 to date. |
| Toledo Edison Co. | July, 1901 | 8 per cent annually from issuance October, 1921, to date. |
| United Electric Light & Power Co. | In 1887 | 6 per cent annually—stock practically all owned by New York Edison Co., which see. |
| United Gas Improvement Co. | Apr., 1888 | 7 per cent annually from issuance May, 1920—common paid not less than 4 per cent since 1889. |
| United Light & Railways Co. | July, 1910 | 6 per cent annually 1910 to date. |
| Utah Power & Light Co. | Sept., 1912 | 7 per cent annually 1913 to date. |
| Virginia Railway & Power Co. | June, 1909 | 5 per cent annually 1910 to 1914—6 per cent 1914 to date—dividends from July, 1919, to July, 1922, paid in stock—dividends now in cash. |
| Washington Railway & Electric Co. | Feb., 1902 | 5 per cent annually 1904 to date. |
| Western Power Corp. | June, 1915 | 4 per cent 1916 to 1919—6 per cent 1919 to date—accumulated unpaid dividends total 13 per cent. |
| West Penn Power Co. | Mar., 1916 | 7 per cent annually 1916 to date. |

## Dividend Record of Electric Light and Power Companies (Continued)

| COMMON STOCK | Incorporated | Dividend Record |
|---|---|---|
| Brooklyn Edison Co. | June, 1890 | Dividends of not less than 6 per cent since 1900—8 per cent from 1903 to date. |
| Buffalo General Electric Co. | Aug., 1892 | Dividends of not less than 5 per cent since 1900—8 per cent 1918 to date. |
| Columbia Gas & Electric Co. | Nov., 1906 | Dividends of not less than 4 per cent—1917 to date. |
| Commonwealth Edison Co. | Sept., 1907 | Dividends of not less than 5 per cent since 1907—8 per cent from 1913 to date. |
| Detroit Edison Co. | Jan., 1903 | Dividends of not less than 4 per cent since 1909—8 per cent from 1916 to date. |
| Edison Electric Illuminating Co. of Boston | In 1886 | Dividends of not less than 5 per cent since 1890—12 per cent from 1910 to date. |
| Hartford Electric Light Co. | In 1881 | Dividends of not less than 8 per cent since 1903—10 per cent from 1919 to date. |
| Indianapolis Light & Heat Co. | Dec., 1904 | No dividend record available. |
| Narragansett Electric Lighting Co. | May, 1884 | 8 per cent annually 1886 to date. |
| New Bedford Gas & Edison Light Co. | ** | Dividends of not less than 6 per cent since 1899—not less than 10 per cent 1905 to date. |
| New York Edison Co. | May, 1901 | 6 per cent annually 1907 to 1915—not less than 7 per cent 1915 to date. |
| Pennsylvania Water & Power Co. | Jan., 1910 | Dividends of not less than 4 per cent since 1914—7 per cent from 1920 to date. |
| Turners Falls Power & Electric Co. | In 1907 | Dividends of not less than 6 per cent 1907 to date. |
| Washington Water Power Co. | In 1889 | Dividends of not less than 4 per cent 1901 to date—7 per cent from 1920 to date. |

*Accumulated dividends on original preferred, amounting to 70 per cent, were paid off in stock Oct. 1, 1922; cash dividends accrue from Oct. 1, 1922.
†Accumulated unpaid dividends on both issues from 1918 paid off by stock in 1922—cash dividends have been resumed.
‡The 5 per cent preferred was cumulative at 4 per cent the first two years and only that amount was paid.
**Incorporated in 1850 but did not acquire light properties until 1884.

Three companies are now paying regular preferred dividends, but still have unpaid accumulations. These are:

(a) The San Joaquin Light & Power Corporation, which accumulated 16½ per cent between 1914 and 1916.

(b) The Western Power Company, the preferred stock of which has an uninterrupted dividend record but still owes 13 per cent back dividends, the explanation being that the dividend was not paid during the first year and was then paid at a reduced rate for four years.

(c) The Nevada-California Electric Corporation, which paid dividends until 1918 and deferred from 1918 to 1922. This was owing largely to slackness in the mining industry. The company has now resumed dividend payments.

Of the fourteen companies having only common stock outstanding:

One company does not make public its record.

Ten companies have an unbroken dividend record of more than fifteen years.

Three companies have an unbroken dividend record of more than five years.

Of the total of eighty-one companies cited—i.e., sixty-seven companies with preferred stock issues and fourteen with common stock—every one is paying current cash dividends.

This record speaks for itself and more than justifies the prevailing popularity of this class of security in the public utility field.

### Customer Ownership a New Factor

It is interesting, furthermore, to bear in mind that another factor has entered into this particular class of investment, a factor which is so comparatively recent as to have scarcely affected the history of those stocks in past years. This new element is "customer ownership." The distribution of preferred stocks among the customers and employees of public utility companies has had the effect of stabilizing the market and of distributing the issues into strong co-operative hands. Undoubtedly this single consideration will have an increasingly potent effect on the investment rating of these securities. It is a subject too broad for discussion here, but it is nevertheless a vital condition that should not be overlooked in the consideration of preferred stocks.

That the present favorable attitude of the investor toward electric light and power preferreds is well justified seems apparent, and that the future holds an attractive promise of appreciation in value for this class of security seems a very reasonable belief.

# Fuel Oil Helps Overcome Strike Menace

**With Slight Changes in the Structure of Its Coal Furnaces the Nebraska Power Company Found That It Was Able to Use This Substitute for Coal Successfully**

By K. R. MacKinnon

Chief Operating Engineer Nebraska Power Company

Among the lessons to be learned from the recent coal strike one should be taken to heart by all public utilities. It is that with present methods of producing coal we must always be prepared to face a prolonged stoppage of the larger part of the supply—a stoppage which cannot be entirely taken care of by increased storage. Unless the work of the President's committee now studying this subject results in some basic changes in the industry, we may expect that there will be periodic upheavals which are bound to cause serious shortages of power.

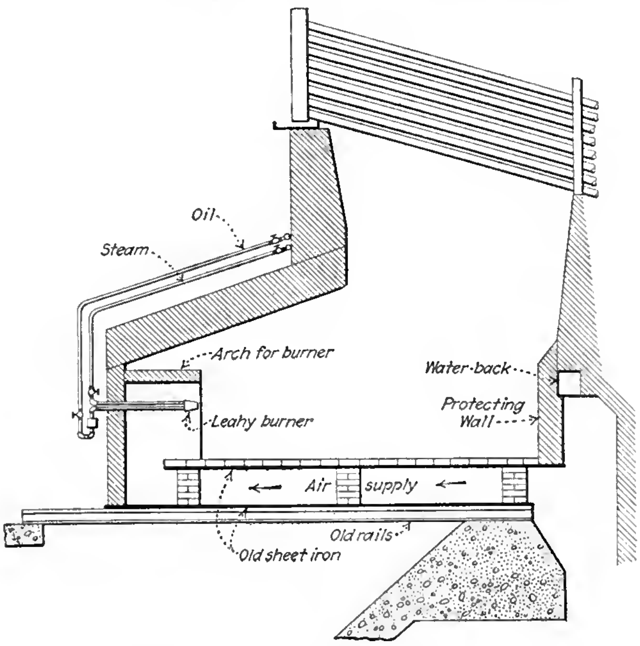
When the recent coal strike had been in effect about four months nearly all public utilities companies found their supply of coal in storage getting dangerously low. Some had exhausted it entirely. A large number turned to oil for relief, with various degrees of success. Numerous cases of secondary combustion and of burned-out grates, baffles or furnaces occurred. It may be that some plants that experimented unsuccessfully can benefit by an account of the methods used to overcome these difficulties in the plant of the Nebraska Power Company.

The boiler equipment in the plant consists of seven 550-hp. Stirlings, eight 508-hp. B. & W. and one 1,450-hp. B. & W. in service, with two more under construction. About Aug. 1, 1922, it was decided to burn oil under the eight 508-hp. B. & W. boilers. They are rather low-set boilers, six having front headers 10 ft. and two having headers 12 ft. above the floor. The Stirling boilers are equipped with an emergency oil system consisting of a 3,750-gal. underground tank, steam pumps, 250-gal. pressure reservoir, steam and oil lines to boilers and Leahy burners. This system is an emergency one only and is not suitable for continuous

use as it is not convenient to provide an adequate air supply for oil while burning coal.

To equip the B. & W. boilers for oil burning, the oil and steam lines were extended into the B. & W. boiler room. The boilers were changed over from chain-grate coal burners to oil burners at the rate of one per day. The work done on each boiler was as follows:

The chain grate was pulled out. A false sheet-iron floor was installed with another one 12 in. above it, so that the air was preheated in passing under the furnace floor from rear to front. The air came from the basement through the ash hoppers, then under the furnace floor to the front of boilers and up to the burners. The ledge plates and waterbacks were protected by side and rear walls built up on the sheet-iron floor to a height of 6 in. above them. A small air space was left under the ledge plates for air to circulate from rear to front into the furnace. Two small arches were built at the front end for the two burners. A firebrick covering was placed on the top floor. The front of the furnace was bricked up, leaving 4½ in. square openings for burners only. Two burners per boiler were used, taken from the Stirling system. The boilers were fired up in each case about eight hours after the work was started.



CHANGING OVER FROM COAL TO FUEL OIL

To equip its 508-hp. B. & W. boilers for burning oil, the Nebraska Power Company pulled the chain-grate stokers out and a false sheet-iron floor was built in. The 12-in. space between the false floor and the bottom of the furnace was utilized for preheating of the air supply, which was brought in from the rear through the basement and ash hoppers. The ledge plates and waterbacks were protected by side and rear walls built up on the false floor and the floor was protected by a layer of firebrick. Temporary arches were built at the front end for the two oil burners.

To control combustion test, ratings of 100, 135, 150, 170, 190 and 200 per cent were run on each boiler, and the draft over the fire was adjusted in each case until the $CO_2$ at the boiler uptake was between 12.5 and 13.0 per cent with no CO. As the oil being used was 36-38 Baumé, and therefore high in hydrogen, it was found that 13 per cent $CO_2$ was as high as it was safe to run. Each boiler-draft gage was then equipped with a card showing the draft over the fire to be used on that boiler at each of the above ratings. The firemen soon became accustomed to this control. and it was found that the $CO_2$ was held very steadily at all times between the limits set. This method was developed after $CO_2$ readings alone had been tried for control—a method which allowed CO to be formed on one occasion, causing secondary combustion and an overheated breeching. An average rating of 170 per cent was maintained on these boilers while burning oil.

The bottom two rows of tubes in all boilers were bored to make sure that no scale was present. This eliminated all chance of trouble from leaks. Previous experience has proved that tubes free from scale will never burn, while even a thin patch of scale will often cause blistering when burning oil. The only trouble that did develop was in the front baffles. The flame impinged on these baffles just above the bridge wall. The intense heat melted the slag which had coated the baffle tile, and in a short time there were numerous holes through the spaces between the tubes and the tile. This difficulty was overcome with an air gun, the baffles being completely smothered with a mixture of finely screened crushed firebrick and fireclay put on with an air blast. This gave excellent results and kept the baffles absolutely tight.

When coal became available the oil supply was cut off very quickly on account of the high cost. Changing back from oil to coal was done at the rate of two boilers per day. The average actual working time taken was one and one-half hours per boiler from the time dismantling was started until coal was being fed by the grate, ready to fire up. The chain of one grate had been taken off to reduce its weight while handling. This grate, measuring 10 ft. 6 in. long by 9 ft. wide, was rechained in seven hours. The furnaces were found to be in excellent condition in spite of their small size. The average furnace volume was 560 cu.ft., which at 170 per cent rating gave 1.5 hp. per cubic foot furnace volume, whereas a properly designed oil furnace generally allows 1 hp. per cubic foot.

### Furnace-Wall Erosion Slight

About 2,000 firebricks per boiler were used for the protection of the walls, ledge plates and waterbacks and for the floors. After two months' use 80 per cent of these bricks were in first class condition and were used in building linings in furnace walls. The erosion of the furnace walls was very slight. This was due to the fact that the spread of the burners was such that the flame did not impinge directly on the walls. If the flame is too wide for the furnace, it will cause very rapid erosion. The ledge plates and waterbacks were found to be unharmed. If occasion should arise again to use oil, the only change in furnace design will be in abolishing the air preheating device and lowering the burners one foot, thus increasing the distance from burner to tubes and increasing the furnace volume about 17 per cent. Burners using steam for atomization give a long, flat flame, and unless the setting is very high this flame at high ratings goes well up into the tubes. The saving that will be effected by complete combustion before the tubes are reached will more than offset any gain due to preheating the air, especially when the preheating is done by the furnace floor.

The monthly over-all boiler and furnace efficiency was 77 per cent, without deducting for steam used for atomization. Daily oil samples were taken and water was measured by Venturi meters. The regulation of steam pressure was done with these boilers, swinging either two or three at a time between 100 and 170 per cent rating. This efficiency compares very favor-

ably with that obtained in plants where the firemen are trained in oil burning. An adequate supply of air under proper control is probably the most important point to be taken care of when burning oil. If the stoker cannot be removed, as in the case of a forced-draft chain-grate or underfeed stoker, special care must be taken to admit air in sufficient quantities. Portions of the stoker and front wall must be removed in nearly every case. The method outlined above for controlling the air supply is extremely simple and is easily learned by the firemen. It is simply the principle of steam-flow-air-flow worked with separate instruments.

Mechanical burners are making great headway in replacing steam atomizers in permanent oil-burning installations; but for temporary work, such as changing over during a coal strike, the steam atomizer is in a class by itself for first cost and speed of installation. In efficiency they break about even. Experience with oil burners was first gained in this plant in the strike of 1919. This was followed in 1920 by several months when there was a shortage of boiler power and poor coal. The Stirling room was then fitted with emergency oil burners to be used in addition to coal for pulling over peaks. The only storage used is a 3,750-gal. underground tank, which is normally kept full of byproduct tar from the city gas works. With eight boilers using oil at the rate of 300 gal. each per hour, this storage was a little too small to be comfortable, but by close watching it was possible to switch the oil cars in such a way that the oil supply did not give out at any time. The experience of this plant is that the equipment required for such emergency service is small and cheap. Coal shortage can be met very quickly and at low installation costs. It is an excellent asset to any plant.

# Letters from Our Readers

**A Place Set Apart for Suggestions, Comments and Criticisms, to Which All Men of the Electrical Industry Are Cordially Invited to Contribute**

## How Shall Our Farms Be Served with Electricity?

*To the Editors of the* ELECTRICAL WORLD:

Your article on "Farm Power as an Issue" (ELECTRICAL WORLD, Feb. 3, 1923, page 257) is no doubt well meant but shoots wide of the mark. The article "Uses of Electrical Energy in Agriculture" (ELECTRICAL WORLD, Feb. 3, 1923, page 268) is also of little interest to American farmers and has little bearing on their conditions, because it is based on uses in England and Europe.

When you consider that rural lines serving the farmer in the Middle West, which is a wealthy, progressive farming territory, will have but three farms to the mile of line, and that each farm must be served with a separate transformer and necessary equipment to protect it from lightning and storms, and that the average farm will use but 240 kw.-hr. a year, you can commence to realize why the farms will not be served with electricity.

We are serving 450 farms in this section of Iowa, distributed over three counties, and we feel that we are able to judge of the conditions and possibilities. The farms we serve use electricity for lighting and to operate household appliances, such as washing machines, vacuum cleaners and flatirons, as well as electric fans, and possibly one-third of the farms have a small motor of 0.5-hp. or 1-hp. rating for pumping water. Most farmers have tractors, and when one considers that a Ford tractor costs but $432 delivered and will plow ten acres per day of ten hours with a kerosene consumption of 20 gal., at a cost of $2 plus oil costing 25 cents, giving a total cost of $2.25, or 22½ cents per acre, one can begin to wake up to the situation. This same Ford tractor can be used for operating a feed grinder and filling silos in the fall after the plowing season is over.

Electric service in England in a densely populated community of very small tracts is one thing, while electric service to farms averaging 160 acres to 200 acres in size is quite another thing. I can see no solution of the question of electric service on the farm until the farmer makes up his mind that he will pay a fair price for the service and that it is not to be compared to the old farm-line telephone systems, which were built in the cheapest possible manner and on which no money has been expended for maintenance, with the final outcome that they are in deplorable condition.

There is this feature in electric service, that it helps the farmer's wife with washing and ironing and makes the home brighter when well lighted; but even this advantage is somewhat discounted when the farmer's family pile into a Ford car and go to the village or town to take in the "movies" once or twice a week.

Further, in the matter of grinding feed for farm use, even this part of the work has been simplified by a mill which has recently been perfected and that will grind corn and oats almost like flour in one operation at the rate of 50 bushels an hour. This results in the farmer taking a load of corn and oats to the mill to have it ground while he is doing his shopping, and in a few hours he is ready to return home with the finest feed for hogs or cows.

Electric farm service is a business proposition and can only be settled the same as any other business, which means that it must have sufficient earnings if it is to survive.

GEORGE S. CARSON, President.
Iowa Gas & Electric Company, Iowa City, Iowa.

[Mr. Carson's idea of the English situation is natural and probably the same that most Americans hold. R. B. Matthews, the author of the paper on English and European practice in the rural use of electrical energy, says in the paper referred to: "For farms of under 150 acres careful thought must be given to insure that an adequate return is obtained for the capital expended, as the number of hours of use of each machine is limited. Similar care must, of course, be taken in designing installations for larger farms, but, as the hours of use are longer, it is not so easy to make a mistake in regard to the equipment." The research work Mr. Matthews has done is concerned with the larger farms that correspond well with Middle Western American farms in size. Just how far the research work done in England will apply in America is, of course, an open question. In human, animal and mechanical power the American farmer is a large power user. He is a great many years behind the other industries in his use of mechanical or electrical forms of energy. He has made up his mind that electrical energy should offer him the same advantages it has given all other industrial pursuits. The basic question is whether any considerable part of his operations can be handled electrically. Agricultural engineers of standing are already taking the position that ultimately a large part of them can be handled electrically at a profit to the farmer. The problem of the central station is either to help prove that these authorities are right and speed the development as rapidly as possible or help prove that the whole idea is fallacious. Accomplishments already noted in the little research work so far undertaken are such that the central station dare not sit still and say, "It cannot be done." Its influence must be actively exerted toward finding the real answer. The problem is fundamentally economic, as Mr. Carson

concludes, and as, too, agricultural men all agree, and if the use of electrical energy is to be established on the farm, it will be on the basis that the lower cost of farm production and better living conditions make it profitable to the farmer to utilize a sufficient volume of energy to enable the central station to furnish the service with profit. There can be no other answer. The issue is already well defined and is not of central-station making. The central station has no choice but to face it intelligently.—EDITORS.]

### Halifax's Hydro-Electric Plant

*To the Editors of the* ELECTRICAL WORLD:

In the Feb. 3 issue of the ELECTRICAL WORLD, page 298, the statement appears that Moncton, N. B., will be the first city in the Maritime Provinces of Canada to obtain power and light from a hydro-electric source, through the early completion of a connection with the Musquash hydro-electric station. Halifax, N. S., has been receiving hydro-electric power since June, 1922, from a development at St. Margaret's Bay. The Province of Nova Scotia built the development and entered into a thirty-year contract with the public utility in Halifax for virtually the entire output of the present development.

A. STUART PRATT,
District Manager.

### Uniform Classification of Accounts

*To the Editors of the* ELECTRICAL WORLD:

My attention has been called to your editorial on uniform classification of accounts in the issue of Jan. 13. I hope that your editorials on other subjects, with which I am not familiar, are based on more complete information or are less partisan, so that those not conversant with the facts may reach accurate conclusions.

I attended the accounting conference last September before the Federal Power Commission. Representatives of the National Electric Light Association, the then president of the National Association of Railway and Utilities Commissioners, now counsel for the National Electric Light Association, and members of the committee on statistics and accounts of the two associations attended the conference and for several days argued in favor of their classification as then drawn. Since then their classification has been again revised, and it is apparently this revised form which you think is the final word on accounting matters. Your editorial is very much in line with some of the statements made at the Washington conference by representatives of the organization mentioned. The editorial impresses me as a bit of propaganda in favor of the classification recommended by the National Association of Railway and Utilities Commissioners and indorsed by the National Electric Light Association.

I assure you that I am not alarmed about your editorial but, rather, amused by it. You adroitly call attention to "certain mandatory practices of the Interstate Commerce Commission," but refrain from stating how such practices came to be written into the federal water-power act and the Federal Power Commission's accounting system. Nor do you point to a single defect in the classification you advocate. Of course, it would have been poor policy for you to do so. However, I feel confident that any impartial critic of accounting systems who will compare the system you favor with that adopted by the Railroad Commission of the State of California will decide in favor of that adopted by the California commission. Not only do I believe that this system is more complete and better adapted to California conditions than the one you advocate, but it also affords the means of keeping accounting work and expense of public utilities at a minimum. In the end the consumer must pay such expense. I have had the consumer's interest as well as the utilities' in mind when reviewing the two systems of accounts.

W. C. FANKHAUSER,
In charge department of finance and accounts.
Railroad Commission of the State of California,
San Francisco, Cal.

[The editorial to which our contributor takes exception dealt with the uniform classification of accounts adopted after much discussion and study by the National Association of Railway and Utilities Commissioners at its annual meeting in Detroit Nov. 14-16, 1922. That classification is at once flexible and universally applicable and does not embody regulatory functions in an accounting system. The Railroad Commission of the State of California, which is a member of the National Association of Railway and Utilities Commissioners, is the only commission which to our knowledge has discarded the work of its own association for that of the Federal Power Commission. Other water-power states in the Far West, like Washington, Idaho, Utah, Wyoming and Colorado, have adopted the "commissioners'" classification. In Oregon a decision favorable to the Federal Power Commission's classification has just been reconsidered and final action is expected in a few weeks. The commissioners' classification needs no justification from us. It speaks for itself, and the fact that it has been so widely adopted proves its worth. Our contributor presumes too much when he implies that no other commission has the interest of consumers and utilities in mind. We prefer to look upon them all as broad-minded and solicitous of the public welfare.—EDITORS.]

### Advantages and Difficulties in Copying Manufacturers' Methods

*To the Editors of the* ELECTRICAL WORLD:

On reading over the excellent article in the Nov. 11 issue of the ELECTRICAL WORLD on a manufacturing company's method of testing meters I was struck with the following differences in manufacturers' and operators' test requirements:

The meters handled by the manufacturer's meter testers are all new, and, except for trouble with defects in material and workmanship, only a few bad meters are encountered, so it becomes largely a problem of getting through as many as possible in a day. Electric service company's meter testers, on the other hand, have to look for trouble due to wear, dirt and other service conditions, and it is of the greatest importance that they be required to look for and remedy these troubles and not be allowed to race for speed only.

The manufacturer puts through so many meters a day that most of the racks can be arranged for one size and type of meter only, but this practice cannot always be followed by operating companies except by the largest.

Nevertheless, a number of the arrangements and methods used by the manufacturer can be utilized to increase speed, convenience and thoroughness. It would be of great value to readers of the ELECTRICAL WORLD if they could hear of meter-testing methods and practice from other manufacturers' men and from utility companies' meter engineers or superintendents. Such an exchange of ideas would acquaint meter engineers with different ideas and arrangements which might be combined to suit local conditions. These very often present a difficult problem for the metermen to tackle. As a general rule the rooms available for tests are not designed and built for the purpose, and a considerable amount of ingenuity has to be exercised in adapting them to laboratories and test rooms.

BEDFORD J. BROWN,
Superintendent Meter Department.
Southern Power Company, Charlotte, N. C.

Installation, Operation, Maintenance, Test and Repair of Generation and Distribution Equipment, and Methods of Economically Utilizing Electric Service in Large Industrial Plants

## Safety Switch Withstands Severe Service

By installing a new safety switch on the control of its motor-driven ice conveyor the Consumers' Company, Chicago, has been able to keep this conveyor in service for more than a year under very severe operating conditions. Withstanding successfully several hundred abrupt starting movements daily is the record of this control switch. The durability of this switch is insured by the four-surface engagements of contracts, the double break, the self-alignment and the absence of springs. The ice conveyor is 80 ft. long and runs the entire length of the ice-storage room. An average of 350 tons has been handled daily with it. Cakes of ice are placed on the conveyor and then the conveyor is started by closing the switch on the loading platform, located in front of the ice house where the ice cake emerges through a narrow chute, whence it is directed to the ice delivery truck. This switch has become so popular that, although several hand-fed exits are available, the ice men prefer to wait their turn to get ice from the motor-driven conveyor.

The safety switch has several important features differing from other safety switches. The main contacts are also the fuse mountings so that when the switch is opened these contacts are swung outward on a center rod.

By closing the switch the contacts are swung inward, thereby closing the circuit. When in this position the switch is foolproof, since there are no live parts exposed. Besides the protection offered by the impossibility of closing the switch when the door remains open, a glass shows the position of the switch itself. When once closed the door can be opened to allow fuse testing, but no live parts are exposed to the operator. No padlock is required since when the switch is opened it is impossible to touch any of the live parts.

The cabinet is made of two parts, one a box body containing the back and sides and the other the switch proper and the door.

All of the apparatus has operated satisfactorily. L. Winkler,

Consumers' Company, Chicago, Ill. Engineer.

## Production Expenses at Connors Creek

### Total Cost of Energy Now 0.577 Cent as Compared with 0.846 Cent for 1921 Peak—Thermal Efficiency of System Is the Best on Record

Although the unit fuel expense was higher and the load factor was lower, the total production expense per kilowatt-hour at the Connors Creek Station of the Detroit Edison Company for the twelve-month period ended Dec 31, 1922, was lower than for the same period ended June 30, 1922, according to figures just made available through the courtesy of Alex Dow, president of the company, and tabulated herewith. Another notable change since the Electrical World last printed these figures (see issue for Sept. 2, 1922, page 487) is the further increase in plant economy, the B.t.u. per kilowatt-hour being 19,660, the lowest since the plant was placed in operation.

The Connors Creek plant is still without economizers, and the average steam pressure at the turbine throttles is 219 lb. gage. The average steam temperature is 585 deg. The kilowatt-hour output given in the

table is net, delivered to the transmission lines as approximately 24,000 volts All energy used in the plant and yards and the losses in the step-up transformers are treated as plant uses so that the output figure is the current sent out and available for sale.

It should also be noted that the Connors Creek plant is not a base-load plant. It takes its share of the fluctuations of the load, which condition is indicated by the variation in the load factor of the station from year to year.

The tendencies in production expense, economy and load factor since 1917 are shown in Fig. 1, while the relation between fuel, wage and superintendence expenses is illustrated in Fig. 2.

The output for the twelve-month period ended Dec. 31, 1922, has increased to 613,263,100 kw., or 10.3 per cent more than for the period ended June 30, 1922. The maximum demand (thirty-minute period) has increased 20.4 per cent and the average load 10.2 per cent, while the load factor has decreased from 52.9 per cent to 48.5 per cent, or by 4.4 per cent.

The total production expense for this period was 0.577 cent per kilowatt-hour, as compared with 0.582 cent for June 30. The lowest figure in the table is 0.334 cent for the period ended June 30, 1917, while the peak was 0.846 cent for the period ended June 30, 1921. Last year's figure is 31.8 per cent less than the peak, but is still 72.7 per cent higher than the figure for the twelve months ended June 30, 1917.

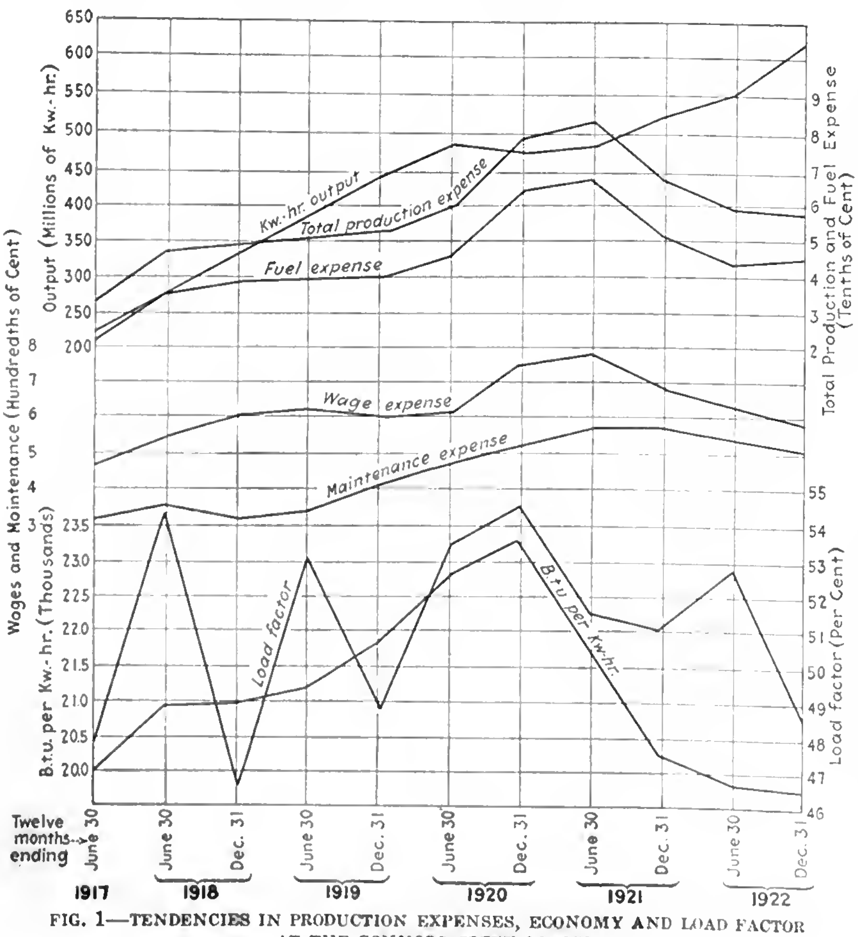

FIG. 1—TENDENCIES IN PRODUCTION EXPENSES, ECONOMY AND LOAD FACTOR AT THE CONNORS CREEK PLANT

## Building an Organization from Within

OPERATION of hydro-electric plants is usually an isolated occupation. No city-bred man can long remain in such a position without becoming restless. Hence the Alabama Power Company draws its isolated-plant operators from among the country folk who live in the vicinity of these plants and who are accustomed to the quiet of the "sticks." With careful training these recruits become good operators, and if paid fair wages and given a good home, as is done in the Alabama system, they may remain company employees for a lifetime. Some of these men turn out to be excellent handlers of men and acquire sufficient technical knowledge to act as superintendents of the station in which they are reared. In any event the company helps its men to find their niche by transferring them from one job to another or from one station to the next, leaving them long enough in one position to find what worth there is in them. Furthermore, it believes in placing responsibility on its men in proportion to the way in which they show they can shoulder it. Sometimes they are even forced to shoulder responsibilities merely to awaken latent ability. This practice eliminates the monotony of the occupation and has usually stimulated increased interest in the job.

### SELECTING THE BEST GRADUATES FROM TECHNICAL SCHOOLS

For another type of man who can grow within the company the Alabama company selects the best graduates it can from technical schools —not alone for scholarship, although a good technical foundation is required, but for alertness, aggressiveness, personality, thoroughness, etc. These men are put through a sort of apprenticeship—perhaps first as a governor-floor attendant or water boy in a power plant, then on the turbine floor, next as switchboard operator and later as an assistant load dispatcher. Then the recruit may be given several months of home office training in the production, distribution, operation and maintenance departments and finally exchanged with an electrical manufacturer who desires to give one of its representatives operating experience. When the man returns from his apprenticeship with the manufacturer it is usually possible to determine what position he will fit into best.

As a result of this type of training he Alabama company is building up real organization which has an opportunity to develop the best in itself for the individual and for the development of an interprising company.

## How to Prevent Priming and Foaming in Boilers

PRIMING, or the mechanical carry- ing of water out of the boiler by eam, is caused by foaming, which in turn caused by the collection of spended matter, such as salts, eases or sewage on the surface of e water. This renders the libera- on of steam bubbles difficult, so that e steam escapes in belches and car- es water with it. The best method r overcoming priming and foam- g, as pointed out in the operat- g code of the Philadelphia Electric mpany, is to reduce the water level d to rid the surface of the foreign aterial. This is most readily done use of both the main and surface ow-offs.

Following are the specific instruc- tions for this operation:

1. Close the feed valve.
2. Bank the boiler.
3. Open the surface blow-off valve d blow down until the water level lowered about one gage.
4. Start from a banked condition.
5. If foaming is not stopped by this thod, shut down the boiler and wash it out.

## Operating Synchronous Motor-Generators

IN THE case of a synchronous motor with a separate direct-cur- rent generator used as an exciter, t exciter voltage must be adjusted to approximately normal value as in- dicated by voltmeter or pilot lamps, according to the operating code of the Philadelphia Electric Company. With the proper rheostat setting this will insure a definite amount of field current to be taken by the motor when the field switch is closed and will cause a minimum amount of cur- rent to be drawn from the alternat- ing-current system.

It is a characteristic of synchro- nous motors that for every load there is a field-current value that gives unity power factor and minimum armature current. Increasing and decreasing the field current from this value give, respectively, a leading and a lagging current of greater value. The generator voltage must be made equal to that of its bus before connecting to it, otherwise a sudden rush of current would flow either from the bus into the machine or from the machine to the bus. This current may be of such value as to trip out both ends of the unit, which would necessitate starting all over again. The instructions for starting a synchronous motor-generator from the alternating current side and for shutting down as abstracted from the above code follow:

### STARTING

1. Close the alternating-current bus switch.
2. Close the starting switch and observe that the rotor turns over.
3. Adjust the exciter voltage to the proper value.
4. When the wattmeter or ammeter shows that the motor is taking minimum power, change to the running side of the compensator. If separate starting and running switches are employed, open the starting and immediately close the running switch.
5. Close the motor-field switch and adjust the field to give minimum armature current.
6. If the generator is compound-wound, close the equalizer switch.
7. Adjust the direct-current voltage to that of the bus and close the circuit breakers and the negative and positive machine switches.

### SHUTTING DOWN

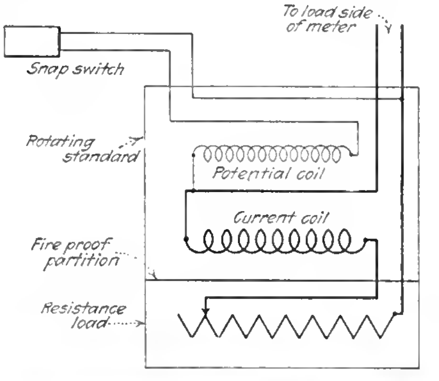
1. Reduce the load on the machine to be taken off to as low a value as possible.
2. Trip the circuit breakers and open the machine and equalizer switches.
3. Open the running and alternating-current bus switches.
4. Cut in all the field resistance and open the field switch.

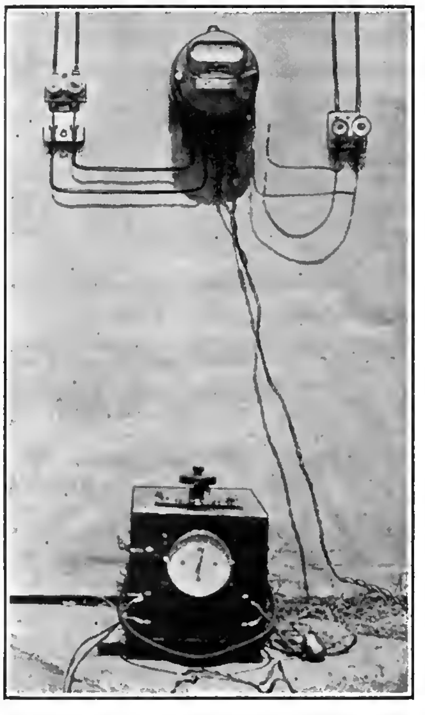
## Compact Meter-Test Set

IN THE testing of house meters much time is lost and inconvenience created by the usual method of connecting separate units containing the rotating standard and the phantom load. In order to eliminate these objectionable features and also to simplify routine testing the writer designed and built the test set illustrated.

The cost of the set, excluding the standard and resistance wire, was $50. One single carrying case, 8 in. x 8 in. x 14 in., contains the rotating standard, the resistance load and all the necessary leads. Instead of requiring 16 connections to be made on the site of the test, a meterman has but to disconnect the load side and connect them to the terminals on the test set.

A variable resistance load, built of five iron elements bolted in asbestos, is contained in the bottom of the case, which is protected by a fireproof composition board. Perforations in the case allow the heat to escape with any temperature rise. This resistance has steps of 1 amp. to 5 amp. at 100 volts, and the steps are all numbered to indicate the load, being made similar to a rheostat. There is a dial on the top of the case, graduated in 100 minor divisions in order to make it easy to read the accuracy of the meter under test in percentage. The accuracy of this test set, like all other rotating standards, depends upon comparison with a fixed standard.





COMBINED ROTATING STANDARD AND LOAD RESISTANCE

The simplicity of the set itself and

the reduction of the number of connections allow an ordinary layman or an unskilled meterman to make rapid tests on the meter site. For, once installed, it is only necessary to turn the rheostat handle to the desired load and note the number of revolutions of the disk on the service meter, then snap the switch on the test set to start or stop. This snap switch also has binding posts so that one can make the leads any desired length.

Pineville, Ky.

## Testing Transformer Oil in Field

A CONTINUOUS round of transformer inspection is made by one Southern power company to test the oil in the tanks. One man is engaged in doing nothing but this work and hence becomes expert at it. Since moisture in the oil is most likely to collect at the bottom of the tank, the test sample is drawn from this point and tested with a portable transformer and a $\frac{1}{10}$-in. disk gap. If the oil will not withstand 15,000 volts, another sample is drawn off 8 in. to 18 in. from the bottom of the tank and tested. If this fails to withstand 15,000 volts, another sample is withdrawn at the oil gage. If this still tests bad, all of the oil is replaced at the earliest opportunity. If it tests all right at the oil gage and not below, that much oil is drawn off and replaced by good oil.

Records of the oil tests are made on forms like the accompanying one and compared with tests which are made at a central point with a standard testing transformer. This is done to keep a check on the accuracy of the portable transformer. The latter has a 110-volt primary which can be energized from any lighting socket which is usually available around a substation.

The minimum test limit of 15,000 volts with a $\frac{1}{10}$-in. disk gap is maintained for all transformers having voltages up to and including 110,000.

With circuit breakers the practice of testing oil is not standardized to so great a degree, first, because facilities are not provided on most of the tanks for withdrawing oil and, second, because there is question regarding the extent to which moisture is seriously harmful in circuit-breaker oil. For lack of other means this company now has to wait until a circuit-breaker is de-energized and disconnected from the buses before any oil samples can be withdrawn. Then access is gained to the interior through the top of the tank by inserting a tube into the oil. The oil tester holds his thumb over the top of the tube until the lower end is at the elevation desired, when the top is opened and oil from the level of the lower end of the tube allowed to flow in. Then the top of the tube is closed again and the tube withdrawn so the oil can be transferred to the sample bottle.

Until tests can be conducted or experience obtained which will show how much moisture in oil is detrimental to circuit-breakers and how much water can collect in the bottom of the tank before opening of the breaker will force it to permeate the entire mass of oil, this company is determining the necessity for replacing all oil by testing samples withdrawn from the zone between the upper and lower contacts of the breaker. Of course, a collection of moisture at the bottom of the tank is drawn off whenever detected, regardless of what the oil tests show. The feeling is expressed that more information is needed regarding the extent to which moisture and carbon in the oil imperil curcuit-breaker performance and that better facilities should be provided for withdrawing samples from breaker tanks.

## Estimated Cost of 75-Mile 110,000-Volt Line

IN CONNECTION with the construction of a new hydro-electric plant at Davis Bridge, Vt., the New England Power Company plans to build a 110,000-volt steel-tower line connecting this station with the Millbury (Mass.) central substation. The estimated cost of the Massachusetts section of the line, 75 miles in length, is given in the accompanying table. The line traverses rural territory.

COST OF 110,000-VOLT TRANSMISSION LINE

| | |
|---|---|
| Rights-of-way | $201,000 |
| Clearing rights-of-way | 64,250 |
| Towers, double-circuit galvanized, spaced 7.7 per mile, 46 ft. to 70 ft. high; power wires spaced 12 ft. and 13 ft. apart in horizontal plane; minimum clearances: ground, 20 ft.; highways, 25 ft.; telephone wires, 8 ft.; towers in place | 655,000 |
| Power wires in place, one three-phase circuit, No. 4/0 B. & S. seven-strand conductors, hand-drawn copper, sagged to reach a tension of 4,000 lb. under ½ in. ice plus 8 lb. wind at 0 deg. F. | 181,200 |
| Insulators, suspension type, standard 10-in. porcelain disks, 8 disks in suspension and 9-in. strain | 54,500 |
| Ground wires in place, two $\frac{7}{16}$-in. double galvanized high-strength steel cables, one carried over each pair of tower legs, to be strung slightly tighter than conductors; strength of 15,000 lb. | 24,100 |
| Special work | 23,700 |
| Telephone line complete, two-wire private line carried on wooden poles about 60 ft. from and parallel to power line | 71,000 |
| Camp operation and tools | 26,900 |
| Superintendence, surveys, payroll, insurance, etc. | 65,200 |
| Total | $1,366,850 |
| Cost per mile | $18,225 |

## A Practical Plan for Wiring Old Houses

**How a Central-Station Company Signs Up the Business for Contractors Who Share in Advertising Expense—Installment Payments Financed by a Local Bank**

By R. F. McGuinness
Lighting Division, Commercial Department, Utica (N. Y.) Gas & Electric Company

AT THE close of the year 1920 our company's records showed that only a small percentage of our cut-ins were made for old houses, most of them being for newly built homes. This indicated that there were a considerable number of unwired dwellings along our existing lines, and as no special effort had been made by the contractors to wire these homes the Utica Gas & Electric Company decided to launch a drive to get the old houses wired and using service.

To determine the number of prospective customers, a careful examination of our ledgers was made and a list prepared of all customers using gas who did not have an electric meter. Upon completion of this survey it was found that 6,100 houses were not wired. The majority of these were along existing lines, and the problem then to be considered was a practicable method of obtaining this business. Our company did not do wiring and did not care to enter this branch of work. It was realized that an important feature of such a campaign was extending terms of payment to the customer; also that many of our contractors could not afford to do wiring on the installment plan. The different features were investigated, one of our local banks was approached relative to handling the accounts, and tentative plans were prepared.

### Getting the Contractors Together

A meeting of all the contractors was called and the subject discussed in detail. It was explained to them that we would furnish the required number of solicitors and turn over the business to them all signed up ready to be installed. The only expense to the contractor would be the advertising, and our company offered to pay $1 toward the fund for every dollar the contractor paid. The arrangement made with the bank for handling the payments and the charge for this service were also explained. The payments were to be made 10 per cent down and the balance in twelve months, payable on the Christmas club plan. The bank's interest and carrying charges were added to the contractors' price for the job.

TABLE I—PRICE LIST OF OUTLETS AND HARDWARE

All openings for switches, receptacles, drop cords and fixtures are considered as outlets and based on a unit price for houses of different classes of construction.

The cost of conduit entrance, switches and receptacles should be added to the price of outlets, and this sum will he the contract price for all labor and material necessary to complete the work as outlined in the schedule.

All extra outlets, switches and receptacles will be charged for according to the class of wiring for which the contract is written.

The minimum number of outlets for any class of wiring shall not be less than four.

| | |
|---|---|
| **Class A—Outlets** | |
| All ceiling or switch outlets located under single flooring, each | $2.90 |
| **Class B—Mixed Flooring** | |
| Prices as per Class A except as below: | |
| Located under double or hardwood flooring: | |
| Ceiling outlet, extra | $1.85 |
| Switch outlet (controlling any center outlet), extra | 1.85 |
| **Class C—Mixed Walls** | |
| Prices as per Class A except outlets appearing on brick walls, extra | $3.15 |
| **Hardware** | |
| Push-button, single-pole switches, each | $1.50 |
| Push-button, three-way switches, pair | 3.60 |
| Snap single-pole switches, each | .85 |
| Flush-plate receptacles (one only) | 5.30 |
| Additional flush-plate receptacles, each | 1.30 |
| **Pilot Light** | |
| Installed in kitchen unless otherwise specified, including receptacle (no lamp) | $3.50 |
| Bullseye in plate including outlet and switch | 8.00 |
| **Conduit Entrance** | |
| Two-wire grounded entrance | $27.50 |
| Three-wire grounded entrance | 30.00 |
| **Garage** | |
| Feeders, using tubes on house | $5.00 |
| Feeders, using conduit on house | 10.00 |
| Maximum distance from house, 50 ft. 5 cents per foot over 50 ft. | |
| **Meter Boxes** | |
| For each additional meter box above two meters | $5.00 |

Ten per cent to be added to the above figures if applicant desires to make payments on the deferred payment plan.

We told them that, in consideration of our company furnishing the solicitors and turning the contract over to them without any effort on their part, and as they would get their money on completion of work, we would insist upon a very liberal price for the wiring. After some discussion, it was decided that a flat price for the entrance, outlets, switches, etc., would be the best way of figuring a job. By such a method many complications which would be sure to arise later were avoided, in addition to saving considerable time figuring the job. This flat price also enabled salesmen not thoroughly familiar with house wiring to arrive at the cost much more easily than if the old method had been adopted. The price for the work was determined by submitting a blank to all the contractors, requesting them to fill in their prices. An average was then taken and this figure used as our price. We investigated prices in other cities before accepting this figure, and found that it compared very favorably with wiring prices in other places. The accompanying price list of outlets and hardware shows the schedule of cost for wiring and terms of payment now in effect.

Fourteen dealers agreed to participate. An advertising budget was prepared and with our own payment we had $1,400 to start the campaign. Later on an additional $800 was added to the fund. Two salesmen were employed, whose business it was to sell house wiring and nothing else. They worked on a commission basis of $5 per contract, with a drawing account of $25 per week. Before making any calls in their territory, we sent out a letter to the owners telling them of our plan for wiring their homes, together with a booklet explaining the easy manner in which already-built houses were wired. This booklet also contained other information relative to the use of appliances in the home and the cost of operating them. The letter was mailed

about two days before the salesman was due to call. Besides paving the way for his visit, it got the customer thinking and talking about electricity in the home, and in many cases it was simply a question of giving a price and getting the contract.

It was decided that our company would not enter into the fixture end of the job but leave that to the customer to call on any of the dealers and select his own fixtures. Such a procedure did not require our salesmen to call back on the customer after the wiring contract was secured in order to change some style of fixture which the customer decided was not satisfactory. However, arrangements were made with the bank whereby the customer could pay for the fixtures on the same plan as the wiring, provided that the fixtures were purchased from one of the fourteen dealers.

### How the Plan Operates

When the contract is brought into the office a letter is mailed the customer acknowledging receipt of his contract, mentioning some of the advantages of electricity in the home and stating the name of the contractor to whom the job was assigned. The agreement is then forwarded to the ledger department, where it is checked for credit. Upon its return it is approved by the commercial manager and sent to the bank. The bank investigates his credit, approves or rejects the contract and returns it to our office. If the contract has been accepted by the bank, it is allotted to one of the dealers in alphabetical order regardless of the amount of the job. In case a dealer telephones us the name of a "prospect" we will have our salesman call, and if he is successful in closing the job it will be given the dealer without penalizing him when his regular turn comes.

Upon completion of the work the customer makes his first payment to the contractor and then gives him a twelve-month note for the balance. The note is indorsed by the contractor and turned over to the bank together with the wiring agreement, the contractor receiving immediately 90 per cent of the amount due him. The balance, or 10 per cent, is retained by the bank until the customer makes all his payments. In this way the contractor is interested in the job until it is fully paid. The bank notifies the customer that it has his agreement, the amount of the monthly payment agreed upon, and incloses a Christmas club booklet.

TABLE II—RESULTS OF UTICA HOUSEWIRING CAMPAIGN FOR YEAR 1922

| | | |
|---|---|---|
| Number of calls made on canvass | | 5,671 |
| Number of estimates given | | 1,067 |
| Number of prospects | | 587 |
| Number of contracts closed | | 438 |
| Number of new customers | | 769 |
| Total amount of contracts | | $32,910 |
| Average amount of contracts | | 75.13 |
| Number of contracts handled through bank | | 213 |
| Cost of obtaining new business: | | |
| Commissions to salesmen | $3,163 | |
| Advertising | 193 | |
| | | $3,356 |
| Number of new contracts solicited but closed independently | | 40 |
| Number of new customers on independent contracts | | 71 |
| Total number of new customers obtained through campaign activities | | 840 |
| Total estimated revenue from all customers secured through campaign activities | | $18,720 |
| Average cost for all customers secured | | $3.99 |
| Total number of houses wired through campaign activities | | 478 |
| Total number of already-built houses connected (city of Utica) | | 1,176 |
| Total number of new houses connected | | 373 |

During the first twelve months of the campaign 565 new customers were added to our lines in addition to the regular trend of business. The wiring for these jobs amounted to $31,438.51, or an average of $76.67 per contract. The amount subscribed by all the contractors for advertising was approximately $1,000. This represented 3.5 per cent of the business secured.

During 1922 we added 840 new customers to our lines through campaign activities. The average cost for obtaining each customer was $3.99. A total of 438 wiring contracts was taken, amounting to $32,909.59, or an average of $75.13 per contract. Table II shows the status of the house-wiring campaign at the end of the year, giving the cost per contract of obtaining the business and its value in gross revenue. This, of course, does not include the natural gain in business which came in unsolicited. During the first year of the campaign the number of meters connected increased from 15,198 to 16,993, a gain of 1,795 for the year 1921, while in 1922 there were 3,203 new meters added, bringing the total on Jan. 1, 1923, to 20,196.

Of the total number of contracts closed from Jan. 1, 1922, 45 per cent were cash jobs. Taking the total gain in residence lighting meters since Jan. 1, we find that we have added 50 per cent more business to our lines, which is directly traceable to our efforts in wiring old houses.

We recently increased the commission paid to salesmen by giving them $4 for each application turned in with a contract. Some contracts call for three meters, in which case the commission paid to a salesman would be $12, provided he turned in the three applications. We are getting more business in this way and the salesman is making more money. The average earning of the salesmen since this change is $38 per week.

We have on file a list of all the unwired homes in the city, together with the majority of the owners' names and addresses. Circular letters are mailed to the owners at different periods of the year urging them to wire their houses. The majority of the cards are also marked with the reason why the owners do not go ahead with the work.

One great advantage of the campaign, besides the additional business, has been to eliminate to a large degree price competition. In the past the contractor would estimate on a job on the hit-or-miss fashion, and in case he knew that other men had estimated he would cut out a plug or switch in order to get the job. Now, since all the reliable contractors are using these figures as a standard, it reduces work on the contractors' part and at the same time gives them a larger volume of business.

## Getting the Message Over to the Public

MOST electric service companies have found it difficult or impossible to get their message to the public through their local newspapers. Usually it has been because they have not investigated what the newspaper requirements are for material acceptable for publication in the reading pages. A few lessons may be learned from the experience of Preston S. Arkwright, president of the Georgia Railway & Power Company, who says: "Before any public relations work can be done there must be good service, and this service must be kept up to the best standard of the country." Next he maintains that the public is always glad to listen to anything about something that vitally affects it, if

told in an interesting manner and in terms it can comprehend. What business has more intimate contact with the public than that of the electric service company? In its various ramifications it has countless phases which would interest the public if related in the right manner. To be effective, however, the stories must be presented in an oral address, illustrated if possible. If properly prepared and presented, they can be made to establish a better understanding of public utility problems, the large investment, the nominal profit allowed by regulation, etc.

In addressing the public, utility men must learn to talk about those phases of their business which vitally affect it or about those which contain an element of "human interest," such as restoring service or constructing plants. Furthermore, they must talk about these things in the terms of the audience's business. For example, cotton-mill men must be addressed in terms of the cotton business and shoe men in terms of the shoe business. Dry statistics should be avoided.

Through his ability as a speaker Mr. Arkwright has made himself so welcome before public audiences that he receives periodic requests to speak before commercial organizations, clubs and civic bodies despite the fact that he refuses to talk in public on anything but the public utility business.

If such messages, prepared to interest the public, are made available to newspapers in typewritten form sufficiently in advance of presentation to allow them to be set in type and published while news, the newspapers are much more likely to use the information and to print it at greater length. Recognizing this, the public relations department of the Georgia company places copies of all addresses made by Mr. Arkwright in the hands of local editors—and of the associated press where the subject is of more than local interest—several hours before the delivery of the address. As a result the company has no difficulty in getting accurate information to the public.

The secret, in brief, is to deliver messages to the public through addresses at public gatherings—to talk about how the utility's activities affect any class of persons in the terms of their own business, and to make copies of the addresses available to the newspapers well in advance of presentation.

## El Paso Exhibits an Electrical Home

THE electrical home idea was introduced to the public of El Paso, Tex., in the recent exhibition of an "electrical home beautiful." During the three weeks the home was open to the public 10,982 people were shown through it, which is a very creditable showing in view of the fact that the population of the city is but 80,000 and of these 60 per cent are Mexicans. Merchandise and appliance sales by the electrical dealers during and after the opening of the home were greater than ever before. Sales of the larger appliances such as washing machines, electric refrigerators and ranges were particularly good.

The home chosen for the exhibition was a seven-room bungalow of Spanish architecture, which had been built for C. A. Winder, manager of the Southwest General Electric Company. To promote the home and raise the necessary funds for advertising and exhibiting, the electrical manufacturers, jobbers, contractors and dealers and the central station joined in forming the El Paso Electric Co-operative Association. Through this organization a total of $2,500 was raised, which was apportioned as follows: Central station, $900; manufacturers, $775; jobbers, $450, and contractors and dealers, $375.

ELECTRIC HOME DISPLAYED IN EL PASO AT AN APPROXIMATE COST OF 2¼ CENTS PER VISITOR

Free publicity concerning the home in the news columns of the local papers amounted to 1,140 in., and 2,895 in. of newspaper advertising was purchased. Based on the attendance and the total amount of money spent in displaying the home, the cost per visitor was approximately 2¼ cents. An attractive booklet entitled "My Own Electric Home in El Paso" was given to each visitor. The suggestion in the title was carried in headings throughout the booklet, as "My Living Room," "My Kitchen," etc., which made a personal appeal to the individual visitor and aroused a desire sooner or later to own a modern electrical home.

## Insull Properties Lead in Americanization Work

WITH 99.79 per cent of their 24,214 employees either American citizens or having signified their intention of becoming such by taking out their first naturalization papers, the group of six utility properties controlled by the Insull interests has an unuaual record. The employees are scattered over the fifteen states in which the companies operate, and the result has been obtained by eighteen months of Americanization work.

A report just made by the company committee in charge shows that on Jan. 1, 1923, 91.97 per cent of the employees were full-fledged American citizens. Those in possession of their first papers and who will gain full citizenship within the next few months total 7.82 per cent, and only fifty-one, or 0.21 per cent, were not citizens or had not taken out first papers. Of these nine are not eligible, being Japanese, East Indian or Filipino students in Chicago schools. In the Commonwealth Edison Company, only eleven out of 6,631 employees were non-citizens, nine of the eleven being the students referred to. The Middle West Utilities showed four non-citizens out of 4,702 employees, the Chicago Elevated Railroads thirty-two non-citizens out of 5,107, and the People's Gas Light & Coke Company's 3,398 employees were all either citizens or had taken out first papers.

Americanization work began with the People's Gas Light & Coke Company, in the summer of 1921, and by the following April every employee was a citizen or on the way to citizenship. The most difficult situation was that of the Chicago, North Shore & Milwaukee Railroad, where men of 15 nationalities, hired

through labor agencies, were scattered in camps along the right-of-way. The first step under the supervision of President Britton I. Budd was discontinuance of the practice of keeping such labor in contractors' boarding camps. Company camps, with better commissaries, baths, close attention to cleanliness and the things that go to make a camp that attracts the better class of men and keeps them contented, were established. Finally, a Y. M. C. A. secretary was employed to look after recreation.
